derived from melting snow and ice, there is no fear of summer shortage, but a winter stoppage may occur. Most of the great lakes of the subalpine region are used as sources of supply, as also are many of the smaller ones; in the latter cases the level of water is frequently raised by a dam. The water is drawn from the bottom of the lake in order to ensure a constant supply in winter. Reservoirs are also constructed in suitable places. The choice of site depends upon several factors, *e.g.*, the impermeable nature of the rocks forming the basin, an adequate supply of water, a minimum amount of deposition of sediment within the basin and the geographical position. Old lake basins have been transformed into reservoirs, *e.g.*, the Barbarine, and many deep gorges have been so utilized. Electric power and lighting are to be found in remote villages.

In the Alps are the sources of the great rivers of western Europe—the Po, Rhone, Rhine and Danube (the actual source of the latter is in the Black Forest, but its main tributaries rise in the Alps). These rivers drain the south, west, north and east slopes respectively, and the Danube also drains the north slope. There exists a very close connection between the direction of the river valleys in the Alps and the geological structure. Most of the valleys are either parallel to or at right angles to the trend of the chains. Examples of the former are the Isère, the Upper Rhone and the Upper Rhine, and of the latter the rivers of the Pennine Alps.

Climate.—It is well known that as we rise from the sea-level into the upper regions of the atmosphere the temperature decreases. Mountain chains cause the prevailing winds to rise to higher altitudes, thus frequently bringing about the precipitation of snow or rain principally upon the windward side. The vast mass of snow, converted into glaciers, maintains a gradation of very different climates within the narrow space that intervenes between the foot of the mountains and their upper ridges; it cools the breezes that are wafted to the plains on either side, but its most important function is to regulate the water-supply of the large region traversed by Alpine streams. Nearly all precipitation during six or seven months is in the form of snow, gradually released by melting in the course of the succeeding summer; even in the hottest and driest seasons the reserves accumulated in the form of glaciers maintain the regular flow of the greater streams. Nor is this all; the lakes that fill several main-valleys on the south side are somewhat above the level of the Lombardy plain, and afford inexhaustible water for that system of irrigation to which it owes its proverbial fertility.

Six regions or zones, which are best distinguished by their characteristic vegetation, are found in the Alps. They are (a) the olive region, (b) the vine region, (c) the mountain region or the region of deciduous trees, (d) the subalpine region or the region of coniferous trees, (e) the Alpine region, (f) the glacial region. Local conditions of exposure to the sun, protection from cold winds or the reverse, as well as height above sea-level, are of primary importance in determining the climate and the corresponding vegetation.

(a) The great plain of Upper Italy is colder in winter than the British Isles. The olive and the characteristic shrubs of the North Mediterranean coasts do not thrive in the open, but olives ripen in sheltered places at the foot of the mountains and along the deeper valleys and the lake shores. The evergreen oak is wild about Lake Garda, and lemons are cultivated on a large scale, with partial protection in winter.

(b) The vine is far more tolerant of cold than the olive, but to produce tolerable wine it demands, at the season of ripening, not much less warmth than the olive, about 68° F average. These conditions are satisfied in the deeper valleys of the Alps, and up to a considerable height on slopes exposed to the sun. Winter snow-covering helps the plant to resist severe and prolonged frosts.

(c) So many varieties of grain are grown under various climatic conditions that their limits of cultivation are less useful for determining zones than are those of the chief deciduous trees—oak, beech, ash and sycamore. These do not reach exactly to the same elevation, nor are they often found growing together; but

their upper limit corresponds accurately enough to the change from a temperate to a colder climate. This limit lies about 4,000 ft. above sea-level on the north side of the Alps, but on the southern slopes it often rises to 5,000 ft., sometimes even to 5,500 feet. The interference of man has in many districts almost extirpated these trees. Their place has been occupied by the Scotch pine and spruce, which suffer less from goats, the worst enemies of trees. The mean annual temperature differs little from that of the British Islands; but snow usually lies for several months, till it gives place to a spring and summer considerably warmer than the average of British seasons.

(d) The Subalpine is the region which mainly determines the manner of life of the peasant population of the Alps. Of the space lying between the summits of the Alps and the low country on either side roughly one-quarter is available for cultivation of which about one-half may be vineyards and corn-fields, while the remainder produces forage and grass. About another quarter is utterly barren, consisting of snow-fields, glaciers, bare rock, lakes and the beds of streams. There remains about one-half, which is divided between forest and pasture, and it is the produce of this half which mainly supports the relatively large population. For a quarter of the year the flocks and herds are fed on the upper pastures; but the true limit of the wealth of a district is the number of animals that can be supported during the long winter, and while one part of the population is engaged in tending the beasts and in making cheese and butter, the remainder is busy cutting hay and storing up winter food for the cattle. The larger villages are mostly in the mountain region, but in many parts of the Alps the villages stand in the subalpine region at heights varying from 4,000 ft. to 5,500 ft. above sea-level, more rarely extending to about 6,000 feet. Coniferous trees, where they have not been artificially kept down, form vast forests. They protect the valleys from destructive avalanches, and, retaining the superficial soil by their roots, they mitigate the destructive effects of heavy rains. On very steep slopes avalanches have frequently torn up the trees, leaving long avenues of varying width through the forests. In such places and in valleys where they have been rashly cut away, and the waters pour down the slopes unchecked, every tiny rivulet becomes a raging torrent, that carries away the soil and subsoil from the grassy slopes and devastates the floor of the valley, covering it with debris and gravel. The prevailing species are the common spruce, the silver fir, the larch and the Scotch pine. The Siberian fir is also found. In the northern Alps the pine forests rarely surpass the limit of 6,000 ft. above the sea, but on the south side they commonly attain 7,000 ft., while the larch, Siberian fir and mughus often extend above that elevation.

(e) Throughout the Teutonic region of the Alps the word *Alp* is used specifically for the upper pastures where cattle are fed in summer, but this region is held to include the whole space between the uppermost limit of trees and the first appearance of permanent snow. Here the characteristic vegetation of the Alps is developed in its full beauty and variety. Shrubs are not wanting. Three species of rhododendron give masses of red or pink flowers; the common juniper rises higher still, along with three species of bilberry; and several dwarf willows attain nearly to the utmost limit of vegetation, the so-called limit of perpetual snow.

(f) On the higher parts of lofty mountains more snow falls in each year than is melted on the spot. A portion of this is carried away by the wind before it is consolidated; a larger portion accumulates in hollows of the surface, and, gradually converted into glacier ice, descends slowly into the deeper valleys, to swell perennial streams. As on a mountain the snow does not lie in beds of uniform thickness, and some parts are more exposed to the sun and warm winds than others, we commonly find beds of snow alternating with exposed slopes covered with brilliant vegetation; and to the observer near at hand there is no appearance in the least corresponding to the term *limit of perpetual snow*, though the case is otherwise when a high mountain-chain is viewed from a distance, for the level at which large snow-beds show themselves along its flanks is approximately horizontal, in so far as conditions are similar. On the opposite sides of the same chain, exposure to sun or to warm winds may cause a wide difference in the level of

permanent snow; but in some cases the increased fall of snow on the side exposed to moist winds may more than compensate increased influence of the sun's rays. Still, even with these reservations, the so-called line of perpetual snow is not fixed. In some parts of the Alps the limit may be set at about 8,000 ft. above the sea, while in others it cannot be placed much below 9,500 feet. As very little or no snow can rest on rocks that lie at an angle exceeding 60°, some steep masses of rock remain bare even near the summits of the highest peaks, but as almost every spot offering the least hold for vegetation is covered with snow, few flowering plants are seen above 11,000 feet. It is, however, want of soil rather than climatic conditions that checks the upward extension of the alpine flora. Increased direct effect of solar radiation compensates for the cold nights, and in the few spots where plants have been found in flower up to a height of 12,000 ft., nothing has indicated that the processes of vegetation were arrested by the severe cold which they must sometimes endure. The climate of the glacial region has often been compared to that of the polar regions, but they are widely different. Here, intense solar radiation by day, which gives the surface when dry a temperature approaching 80° F, alternates with severe night frost. There, a sun which never sets sends feeble rays that maintain a low equable temperature rarely rising more than a few degrees above the freezing-point. Hence the upper region of the Alps sustains a far more varied and brilliant vegetation.

Flora.—The Alps owe the richness and beauty of their plant life partly to their position as the natural boundary between "Baltic" and "Mediterranean" floras, but chiefly to the presence on their heights of a third flora which has but little in common with either of the others. The stronghold of this last, the distinctively "Alpine" flora, is the region above the tree-limit. Its closest relationship is with the flora of the Pyrenees; but an alpine flora is characteristic of all the lofty mountains of central Europe. According to J. Ball, 2,010 well marked species of flowering plants occur within the limits of the Alps. If now we confine our attention to the alpine and higher regions of the Alps and exclude from our list all those plants which are not less abundant in the lowlands, we have left some 700 species. We must observe, as regards the plants of the lower alpine region, that it is the actual presence of a forest vegetation, rather than the theoretical tree-limit, which affects their vertical distribution; so that, e.g., they overflow into the extensive clearings made by man in the primeval mountain forests. Indeed, an analysis of the composition of the alpine flora as a whole leads to the conclusion that the chief bond of union between its members consists in the treeless character of their habitat.

We may broadly distinguish two main geographical elements in the alpine flora, namely, the northern element and the endemic element. This division (which is not, however, strictly exhaustive) directs special attention to what is undoubtedly the most striking feature of the flora, namely, that of its 693 species no less than 271 reappear in the extreme north. This relation of the arctic to the alpine flora is all the more remarkable in view of the very important differences between the arctic and alpine climates. The following circumpolar species are common, and widely diffused throughout the whole of the Alps: *Silene acaulis*, *Dryas octopetala*, *Saxifraga oppositifolia*, *S. aizoides*, *S. stellaris*; *Erigeron alpinus*, *Azalea procumbens*, *Myosotis alpestris*, *Polygonum viviparum*, *Salix retusa*, *S. herbacea*, *Phleum alpinum*, *Juniperus nana*. The proportion of northern forms, as regards both species and individuals, increases until, on islands of rock above the snow-line, it is equal to the endemic element. Northern flowers of the snow-region include *Silene acaulis*, *Eritrichium nanum*, and *Arenaria ciliata*. On the other hand, typical endemic species of this highest zone are *Androsace helvetica*, *A. glacialis*, *Petrocallis pyrenaica*, and *Cherleria sedoides*. All the plants just named are "cushion-plants." Their compact, moss-like growth and general structural peculiarities are analogous adaptations to the dry cold of their habitat. Among the northern plants of the alpine zone, in the narrower sense of the term (i.e., of the region between the tree-limit and the snow-line), there is a marked predominance of species that affect moist localities; and, conversely, the majority

of alpine flowers of wet habitat are found also in the north. For example, in the genus *Primula*, a highly characteristic genus of the alpine flora, whose members are among the most striking ornaments of the rocks, the single northern species, *P. farinosa*, grows only in marshy meadows. On the whole, then, adaptation to cold and wet is the note of the northern element.

During the glacial period, in the ice-free belt, between the northern ice-sheet and the vastly extended glaciers of the Alps, the two floras found refuge and congenial conditions; fossils confirm this view. With the return of a milder climate, the so-called northern forms of the present alpine flora were split in two, one portion following close on the northern ice in its gradual retreat to the Arctic, the other following the shrinking glaciers till the plants were able to establish (or re-establish) themselves on the slopes of the Alps. The same explanation covers the case of the similarity of the flora (not merely as regards the northern element) on all the high mountains of central Europe. Beyond this, disagreement begins between the most eminent writers on the subject. While some (e.g., Sir J. D. Hooker, Heer) regard the Arctic, and some (e.g., Wettstein) the Alps, as the original home of the bulk of the "northern" element, others (e.g., Ball, Christ) locate this in the highlands of temperate Asia. For it is a remarkable fact that, of the 230 northern species which are most typical of the far north, 182 are found also in the Altai (taking this as a collective name for the mountains that form the southern boundary of Siberia). In any case, however, the migration of these plants to the Alps must for the most part have taken place via the Arctic. The possibility of any extensive east to west migration having taken place direct from the Altai to the Alps seems excluded by the fact that 50% of the arctico-altaic alpine plants are absent from the Caucasus. On the whole, a common origin in the north for at least the arctico-altaic group of alpine plants seems to be the most reasonable hypothesis. A score of species are common to Alps and Altai, but a larger number of arctic-alpine forms are absent from the Altai.

Side by side with the northern element we find a group of species usually spoken of as the xerothermic or meridional element. These do not, however, form an "element," in the strict geographical sense in which this term is otherwise used here. They are those species which, on general phytogeographical grounds, must be regarded as having originated under steppe-like conditions. Their affinities are chiefly, with the present Mediterranean flora—about 50 are of presumably Mediterranean origin—and a large proportion of them are restricted to the southern slopes of the Alps. The following, however, among others, are distributed throughout the whole, or a great part, of the range:—*Colchicum alpinum*, *Crocus vernus*, *Orchis globosa*, *Petrocallis pyrenaica*, *Astragalus depressus*, *A. aristatus*, *Oxytropis Halleri*, *Eryngium alpinum*, *Erica carnea*, *Linaria alpina*, *Globularia nudicaulis*, *G. cordifolia*, *Leontopodium alpinum*. The last named (the well-known "edelweiss") is at the present day characteristic of the Siberian steppes. The presence of these plants among the alpine flora is traceable to the steppe-like conditions which prevailed in central Europe both during the warmer inter-glacial periods and (probably) for a time after the close of the ice-age. Subsequently, as the climate of the plains assumed a colder and more humid character, they retired before the invading forests to the high mountains. Here, in the intenser insolation which they enjoy, they seem to find a compensation for the drawbacks incidental to the altitude.

As regards the endemic element as a whole, the question as to the time and place of its origin is of a highly complicated and controversial nature. The question, too, in the case of this element, is necessarily of genetic rather than purely geographical scope. It must suffice to say that the weight of scientific opinion inclines to the view that at least the majority of endemic species are of pre-glacial origin, and are either strictly indigenous or products of the neighbouring lowlands. About 40% of the endemic element in the alpine flora are endemic also in the narrower sense, i.e., they are confined to the Alps. The following is a list of the most thoroughly characteristic alpine plants—all of them *ipso facto* members of the endemic element—which are at once peculiar to the Alps (or practically so) and widely distributed within the limits

of the chain. These are:—*Festuca pulchella*, *Carex microstyla*, *Salix caesia*, *Rumex nivalis*, *Alsiue aretioides*, *Aquilegia alpina*, *Thlaspi rotundifolium*, *Saxifraga seguieri*, *S. aphylla*, *Astragalus leontinus*, *Daphne striata*, *Eryngium alpinum*, *Bupleurum stellatum*, *Androsace helvetica*, *A. glacialis*, *Gentiana bavarica*, *Phyteuma humile*, *Campanula thyrsoidea*, *C. cenisia*, *Achillea atrata*, *Cirsium spinosissimum*, *Crepis terglouensis*.

Fauna.—The fauna of the lower zones in the Alps is, on the northern side of the chain, practically identical with that of central Europe, and on the southern side with that of the Mediterranean basin. But in the higher regions it presents many features of special interest. It seems, therefore, best to treat here principally of the animal inhabitants of the high Alps.

Though among mammalia—as also birds—there are but few forms peculiar to the Alps, many interesting animals have found in the high mountains at least, a temporary refuge from man. The European bison, the urus, the elk, the wolf and the wild swine have disappeared. But the lynx (*Lynx lynx*) lingers in remote parts, as also the brown bear (*Ursus arctos*) in the dense forests of the Lower Engadine. The fox (*Vulpes vulpes*), the stone-marten (*Martes foina*) and the stoat or ermine (*Putorius erminea*) range in summer above the tree-limit. The Ungulata are represented by a few chamois (*Rupicapra tragus*) and a rare bouquetin or steinbock (*Capra ibex*). The former—the sole representative, in western Europe, of the antelopes—is found elsewhere only in the Pyrénées, Carpathians, Caucasus and the mountains of eastern Turkey; the latter survives only in the eastern Graian Alps. Of the Rodentia the most interesting and conspicuous is the marmot (*Arctomys marmota*), which lives in colonies close to the snow-line. The snow-mouse (*Arvicola nivalis*) is confined to the alpine and snow regions, and is abundant at these levels throughout the whole chain of the Alps. The mountain hare (*Lepus variabilis*) replaces the common hare (*Lepus europaeus*) in the higher regions; though absent from the intervening plains it again appears in the north of Europe and in Scotland. Among the Insectivora, the alpine shrew (*Sorex alpinus*) is restricted to the Alps. Of the Chiroptera (bats) only *Vesperugo maurus* is characteristically alpine.

The birds of the Alps are proportionately very numerous. The lammergeyer (*Gypaetus barbatus*), once common, is now extremely rare, but the golden eagle (*Aquila chrysaetos*) still holds its own. Some of the smaller birds of prey are not uncommon, but there is none that can be regarded as specially characteristic either of the Alps as a whole or of the alpine region. As characteristic birds of the snow-region may be mentioned the alpine chough (*Pyrrhonorax alpinus*), which is frequently seen at the summits even of the loftiest mountains, the alpine swift (*Apus melba*), the wall-creeper (*Tichodroma muraria*), snow-finch (*Montifringilla nivalis*) and ptarmigan (*Lagopus mutus*); the geographical distribution of this last being similar to that of the mountain hare. The black redstart (*Ruticilla titys*), though common in the lower regions, is also met with in fair numbers almost up to the snow-line. The raven (*Corvus corax*) is fairly common in the alpine and sub-alpine regions. On the highest pastures we find, further, the alpine accentor (*Accentor collaris*) and the alpine pipit (*Anthus spinoletta*). The crag-martin (*Cotyle rupestris*) haunts lofty cliffs. On the upper verge of the pine forests, or in the scrubby vegetation just beyond, the following are not uncommon:—black woodpecker (*Picus martius*), ring-ousel (*Turdus torquatus*), Bonelli's warbler (*Phylloscopus bonelli*), crested tit (*Parus cristatus*), citril finch (*Citrinella alpina*), siskin (*Chrysomitris spinus*), crossbill (*Loxia curvirostra*), nutcracker (*Nucifraga caryocatactes*), blackcock (*Tetrao tetrix*) and the alpine varieties of the marsh-tit (*Parus balustris borealis*) and tree-creeper (*Certhia familiaris costae*).

The remaining classes of Vertebrata are sparsely represented in the high Alps, and what species occur are mostly common to the plains as well. Among the remaining land vertebrates only the black salamander (*Salamandra atra*) is exclusively alpine. This animal, though a member of the Amphibia, is terrestrial and viviparous.

The former connection between the Arctic and the Alps, which

has left such unmistakable traces in the present alpine flora, affords, as regards the fauna also, the only possible explanation of the present geographical distribution of many alpine forms; but it is chiefly among the Invertebrata that we find this collateral testimony to the influence of the glacial period. In this respect we may note that two small crustaceans, *Diaptomus bacillifer* and *D. denticornis*, swarm in the ice-cold waters of the highest alpine tarns throughout the entire chain; and the former of these is also a characteristic inhabitant of pools formed from melting snow in the extreme north. Among the remaining divisions of Invertebrata special mention may be made of the air-breathing Arthropoda—on the whole the most important and interesting group. About one-third of the animals belonging thereto that occur in the higher regions are exclusively alpine (or alpine and northern); these characteristically alpine forms being furnished chiefly by the spiders, beetles and butterflies. Most numerous are the beetles. Those of the highest zone are remarkable for the great predominance of predacious species and of wingless forms. In this last respect they present a striking analogy with the endemic coleopterous fauna of oceanic islands. As for the butterflies, not more than one-third of the species found in the alpine region occur in the neighbouring lowlands. The relations between alpine butterflies and plants are especially interesting, as regards not only their bionomic interdependence but also the analogies of their geographical distribution. It should be noted that butterflies are the chief agents in securing the continued existence of such alpine flowers as depend on insect fertilization, the other insect fertilizers being mostly wanting at great heights.

Inhabitants of the Alps.—From ancient times we have only scanty mention of Alpine peoples by classical writers, with a few references to conquests by Augustus and to later movements of Teutonic tribes of the 5th and 6th centuries. To them, as to Frankish kings and emperors, the Alps offered a route rather than a residence. In the case of the Western Alps (minus the bit from the chain of Mont Blanc to the Simplon, which followed the fortunes of the Valais), a prolonged struggle for the Alpine region took place between the feudal lords of Savoy, the Dauphiné and Provence. In 1349 the Dauphiné fell to France, while in 1388 the county of Nice passed from Provence to the house of Savoy, which also held Piedmont as well as other lands on the Italian side of the Alps. The struggle henceforth was limited to France and the house of Savoy, but little by little France succeeded in pushing back the house of Savoy across the Alps, thus forcing it to become a purely Italian power. One turning-point in the rivalry was the treaty of Utrecht (1713), by which France gave up to Savoy the districts (all forming part of the Dauphiné and lying on the Italian slope of the Alps) of Exilles, Bardonnèche, Oulx, Fénestrelles and Château Dauphin, while Savoy handed over to France the valley of Barcelonnette, situated on the western slope of the Alps and forming part of the country of Nice. The final act in the long-continued struggle took place in 1860, when France obtained by cession the rest of the county of Nice and also Savoy, thus remaining sole mistress on the western slopes of the Alps.

In the Central Alps the chief event, on the north side of the chain, is the gradual formation from 1291 to 1815 of the Swiss Confederation and the independent confederations of the Grisons and the Valais, which became full members of the Swiss Confederation only in 1803 and 1815 respectively. The Forest Cantons in the 15th century won the Val Leventina as well as Bellinzona and the Val Blenio (though the Ossola valley was held for a time only), while the Grisons added to the Val Bregaglia (which had been given to the bishops of Coire in 960 by the emperor Otto I.) the valleys of Mesocco and of Poschiavo. Further, in 1512, the Swiss Confederation won the valleys of Locarno with Lugano, which, combined with the 15th century conquests by the Forest Cantons were formed in 1803 into the new Canton of Ticino or Tessin. On the other hand, the Grisons won in 1512 the Valtellina, with Bormio and Chiavenna, but in 1797 these regions were finally lost to it as well as to the Swiss Confederation, though the Grisons retained the valleys of Mesocco, Bregaglia and Poschiavo, while in 1762 it had bought the upper bit of the valley of Münster that lies on the southern slopes of the Alps.

In the Eastern Alps the political history relates simply to the advance or retreat of the house of Habsburg. The Habsburgers' ruined castle still stands in the lower valley of the Aar; they lost this district to the Swiss in 1415, and won the duchy of Austria with Styria in 1282, Carinthia and Carniola in 1335, Tirol in 1363 and the Vorarlberg in bits from 1375 to 1523, not to speak of minor "rectifications" of frontiers on the northern slope of the Alps. But on the other slope their progress was slower, and finally less successful. It is true that they early won Primiero (1373), as well as (1517) the Ampezzo valley and several towns to the south of Trent. In 1797 they obtained Venetia proper, in 1803 the secularized bishoprics of Trent and Brixen (as well as that of Salzburg, more to the north) besides the Valtellina region, and in 1815 the Bergamasque valleys, while the Milanese had belonged to them since 1535. But in 1859 they lost to the house of Savoy both the Milanese and the Bergamasca, and in 1866 Venetia proper also, and in 1918-19 the Trentino. The gain of the Milanese in 1859 by the future king of Italy (1861) meant that Italy then won the valley of Livigno (between the Upper Engadine and Bormio), besides the county of Tenda (obtained in 1575, and not lost in 1860), with the heads of certain glens in the Maritime Alps, reserved in 1860 for reasons connected with hunting. After a decisive plebiscite, Vorarlberg requested to be admitted into the Swiss Confederation in 1919, but the request was not granted in the Treaty of St. Germain. By this same treaty, a large portion of the Southern Alps, much of which was held by them at the close of the World War (1914-18), passed into the legal possession of Italy, and the boundary between that country and Austria was readjusted. The southern frontier of Austria was not altered along the Swiss section, but eastward from Gruben it now passes through Dreiherrn Spitz, then south-east of Helm Spitz and along the summit ridge of the Carnic Alps to Grintove, and northward to Unter Drauberg, where it again turns east, and on to Spielfeld. The frontier between Italy and Yugoslavia branches off and passes southward from Tarvis (south-west of Villach). By the addition of this territory of German-speaking peoples to Italy the number of sections of the Alps in which the natives do not speak the tongue of the country was increased. In Italy there are also some French-speaking districts (the Waldensian valleys as well as the Aosta and Oulx valleys). In Switzerland there are Italian-speaking regions, as well as some spots (in the Grisons) where the old Romance dialect of Romansch or Ladin survives; while in Austria, besides German, Italian and Ladin, we have a Slavonic-speaking population in the South-Eastern Alps. The highest permanently inhabited village in the Alps is Juf, 6,998ft. (Grisons); while in the French Alps, L'Écot, 6,713ft. (Savoy), and St. Véran, 6,726ft. (Dauphiné), are rivals; the Italian Alps boast of Trepalle, 6,788ft. (between Livigno and Bormio), and the Tirolese Alps of Ober Gurgl, 6,322ft., and Fend, 6,211ft. (both in the Oetzthal).

Exploration of the High Alps.—About 20 glacier passes were certainly known before 1600, about 25 more before 1700 and yet another score before 1800; but though the attempt of P. A. Arnod (an official of the duchy of Aosta) in 1689 to "re-open" the Col du Géant may be counted as made by a non-native, we do not come upon another case of the kind till the last quarter of the 18th century. The two earliest recorded ascents of high peaks were due to non-natives, that of the Rochemelon in 1358 having been undertaken in fulfilment of a vow and that of the Mont Aiguille in 1492 by order of Charles VIII. of France, in order to destroy its reputation for inaccessibility; in 1555 Conrad Gesner climbed the grassy mound of the Gnepfstein, the lowest and the most westerly of the seven summits of Pilatus. The two first men who really systematically explored the regions of ice and snow were H. B. de Saussure (1740-99), as regards the Pennine Alps, and the Benedictine monk of Disentis, Placidus à Spescha (1752-1833, most of whose ascents were made before 1806), in the valleys at the sources of the Rhine. In the early 19th century the Meyer family of Aarau conquered in person the Jungfrau (1811) and by deputy the Finsteraarhorn (1812), besides several glacier passes, their energy being entirely confined to the Bernese Oberland. Their pioneer work was continued, by a number of Swiss, among whom

were Gottlieb Studer (1804-90) of Bern, and Edouard Desor (1811-82) of Neuchâtel. The first-known English climber in the Alps was Colonel Mark Beaufoy (1764-1827), who in 1787 made an ascent (the fourth) of Mont Blanc, a mountain to which his fellow-countrymen long exclusively devoted themselves, with a few noteworthy exceptions, such as Principal J. D. Forbes (1809-68), A. T. Malkin (1803-88), John Ball (1818-89) and Sir Alfred Wills (b. 1828). Around Monte Rosa the Vincent family, Josef Zumstein (1783-1861) and Giovanni Guifetti (1801-67) did good work during the half century between 1778 and 1842, while in the Eastern Alps the Archduke John (1782-1859), Prince F. J. C. von Schwarzenberg, archbishop of Salzburg (1809-85), Valentine Stanig (1774-1847), Adolf Schaubach (1800-50), above all, P. J. Thurwieser (1789-1865), deserve to be recalled as pioneers in the first half of the 19th century. The English Alpine Club was founded in the winter of 1857-58 followed in 1862 by the Austrian Alpine Club (which in 1873 was fused, under the name of the German and Austrian Alpine Club, with the German Alpine Club, founded in 1869), in 1863 by the Italian and Swiss Alpine Clubs and in 1874 by the French Alpine Club. These clubs have explored the peaks, built huts, trained guides and published journals. The two sub-joined lists give the dates of the conquest of about 50 of the greater peaks (apart from the two climbed in 1358 and in 1492, *see above*), achieved before and after Jan. 1, 1858.

(1) Before Jan. 1, 1858:—Titlis (1744), Ankogel (1762), Mont Vêlan (1779), Mont Blanc (1786), Rheinwaldhorn (1789), Gross Glockner (1800), Ortler (1804), Jungfrau (1811), Finsteraarhorn (1812), Zumsteinspitz (1820), Tödi (1824), Altels (1834), Piz Linard (1835), Gross Venediger (1841), Signalkuppe (1842), Wetterhörner (1844-45), Mont Pelvoux (1848), Diablerets and Piz Bernina (both in 1850), highest point of Monte Rosa (1855), Laquinhorn (1856) and Pelmo (1857).

(2) After Jan. 1, 1858:—Dom (1858), Aletschhorn, Bietschhorn and Grand Combin (all in 1859), Grand Paradis and Grande Casse (both in 1860), Weisshorn, Monte Viso, Gross Schreckhorn, Lyskamm and Wildspitze (all in 1861), Dent Blanche, Monte della Disgrazia and Täscherhorn (all in 1862), Marmolata, Presanella, Pointe des Ecrins and Zinal Rothhorn (all in 1864), Matterhorn, Ober Gabelhorn, Aiguille Verte and Piz Roseg (all in 1865), Langkofel (1869), Cimon della Pala (1870), Rosengarten (1872), Meije (1877), Aiguille du Dru (1878), Punta dell' Argentera (1879), Aiguille des Charmoz (1880), Aiguille de Grépon (1881) and Aiguille du Géant (1882).

BIBLIOGRAPHY.—For a longer list of works on the Alps *see* the catalogue of the (English) Alpine Club Library, also A. Wäber's *Landes- und Reisebeschreibungen der Schweiz* (1899, suppl. 1907); W. A. B. Coolidge, *List of Works of W.A.B.C.* (1912) and A. J. Butler, *Some Notes on Alpine Books* (1926).

For general works on the Alps *see* Sir W. M. Conway, *The Alps* (1904, new ed. 1910); N. Zuntz and others, *Hohenklima und Bergwanderungen in ihrer Wirkungen auf den Menschen* (1906); H. Mettrier, *Pierre d'Avity et des Alpes* (1907); F. Briot, *Les Alpes Françaises* (1907); W. A. B. Coolidge, *The Alps in Nature and History* (1908); A. Dreyer, *Der Alpinismus und der Deutsch-Österreichische Alpenverein* (1909); J. Perreau, *L'Épopée des Alpes* (1903-12); A. H. M. Lunn, *The Alps* (1914); R. A. Cram, *The Heart of Europe* (1916); P. Stéphani, *Les Tunnels des Alpes* (1919); D. W. Freshfield, *Below the Snow Line* (1923); S. Butler, *Alps and Sanctuaries of Piedmont and Canton Ticino* (new ed. 1923); L. W. Collet, *Les Lacs* (1925) and Von O. Flückiger, *Der Schweiz, Natur und Wirtschaft* (1926).

For Alpine legends *see* M. Savi-Lopez, *Leggende delle Alpi* (1889) and for Alpine poetry *see* E. A. Baker and F. E. Ross, *The Voice of the Mountains* (1905); A. von Haller, *Die Alpen* (new ed. 1902); H. E. Jenny, *Die Alpendichtung in der deutschen Schweiz* (1905); J. Adam, *Der Natursinn in der deutschen Dichtung* (1906); G. W. Young, *Wind and Hill* (1909); H. Spender, *In Praise of Switzerland* (1912); A. H. M. Lunn, *The Englishman in the Alps* (1913); R. Thirlmere, *Alpine and other Lyrics* (1926); and for Alpine dialects *see* the great Swiss Dialect Dictionary ("Schweiz Idiotikon") in course of publication since 1881.

geschichte (1906); H. Pécout *Études sur le droit privé des hautes vallées alpines de Provence et la Dauphiné au Moyen-âge* (1907); H. Hartmann, *Das Berner Oberland in Sage und Geschichte* (1909); H. S. Wilkinson, *Hannibal's March through the Alps* (1911); D. W. Freshfield, *Hannibal Once More* (1914); J. Hess, *Histoire illustrée de la région des Alpes-Maritimes* (1915); A. Brun, *Memoires des alpen Toni Brun, Bergführer von Flims* (1917); A. Castaing, *Histoire générale des Alpes Françaises des origines jusqu'à nos jours* (1919); F. F. Tuckett, *A Pioneer in the High Alps* (Letters, etc., of F.F.T. 1920).

The following is a selection from descriptive works published since 1900:—A. Guébbard, *Notes sur les Alpes Maritimes* (1901); E. Whymper, *The Valley of Zermatt and the Matterhorn and Chamonix and the Range of Mont Blanc* (new eds. 1906) and *Scrambles among the Alps* (new ed. 1908); C. Rey, *The Matterhorn* (1907); D. Baud-Bovy, *La Meije et les Ecrins* (1907); C. F. Wolff, *Monographie der Dolomitenstrasse* (1908); A. von Radio-Radies, *Spezial-Führer durch das Dachsteingebirge und die angrenzenden Gebiete* (1908); P. Joanne, *Savoie* (1908); J. Sölch, *Studien über Gebirgspässe, mit besonderer Berücksichtigung der Ostalpen* (1908); C. Falke, *Im Banne der Jungfrau* (1909); H. Ferrand, *Les Montagnes dauphinoises* (1909); M. Meyer, *Deutsche Alpen* (1910); H. Ferrero, *The Valley of Aosta* (1910); S. H. Hamer, *The Dolomites* (1910); C. Schuster, *Peaks and Pleasant Pastures* (1911); H. Ferrand, *Le Mont Blanc d'aujourd'hui* (1912); J. Grande, *The Bernese Oberland in Summer and Winter* (1911); H. Balavoine, *Dans les Alpes et le Jura* (1911); E. Gaillard, *Les Alpes de Savoie* (1912); G. Tardieu, *Les Alpes de Provence* (1912); L. M. Davidson, *The Gates of the Dolomites* (1912); C. Rey, *Peaks and Precipices* (1914); C. Durier, *Le Mont Blanc* (1919); A. Frey, *Die Österreichischen Alpenstrassen in früheren Jahrhunderten* (1919); P. Arbos, *La Vie Pastorale dans les Alpes Françaises* (1922); R. Bagot, *The Lakes of Northern Italy* (1924); J. Vallot and others, *Description Générale du Massif du Mont-Blanc* (1924); H. Quigley, *Lombardy, Tyrol, and the Trentino* (1925); Gabriel Faure, *The Dolomites* (1925); E. L. Broadbent, *Under the Italian Alps* (1925); Blakeney, *Peaks, Passes, and Glaciers* (1926); G. Chabat, *Les Plateaux du Jura Central* (1927).

For accounts of travels in the Alps see P. H. Scheffel, *Verkehrsgeschichte der Alpen* (1908); F. Harrison, *My Alpine Jubilee* (1908); C. L. Freeston, *The High-Roads of the Alps* (1910); W. Larden, *Recollections of an old Mountaineer* (1910); G. D. Abraham, *Mountain Adventures at Home and Abroad* (1910); H. Ferrand, *La Route des Alpes Françaises* (1912); A. C. Knowles, *Adventures in the Alps* (1913); A. Fischer, *Hochgebirgswanderungen in den Alpen und im Kaukasus* (2 vols. 1913); L. Purtscheller and H. Hess, *Der Hochtourist in der Ostalpen* (1910); R. Roschnik, *Führer durch die Julischen Alpen* (1914); E. S. Salisbury, *Rambles in the Vaudese Alps* (1916); H. Aurenche, *A Venise par les Dolomites* (1919); H. Ferrand, *Nice to Evian* (1925); E. V. Lucas, *Zigzags in France* (1925); C. L. Freeston, *Alps for the Motorist* (1926); J. F. Muirhead, *The Wayfarer in Switzerland* (1926); S. H. Hamer, *A Wayfarer in the Dolomites*, and C. B. Waterlow, *Routes des Alpes—a Motorist's Guide to the Great French Alpine Roads*.

Some accounts of climbing and other Alpine sports are—J. Tyndall, *The Glaciers of the Alps and Mountaineering in 1861* (reprint 1906); E. Whymper, *Scrambles in the Alps* (reprint 1908); E. Zsigmondy, *Die Gefahren der Alpen* (1908); Sir W. M. Conway, *The Alps from End to End* (reprint 1910); G. D. Abraham, *On Alpine Heights* (1919); G. W. Young, *Mountain Craft* (1920) and G. D. Abraham, *Swiss Mountain Climbs* (reprint 1926).

There are a large number of excellent guide books for various parts of the Alps. These are revised periodically and so kept up to date. The most important are the following:—Karl Baedeker, *Italy from the Alps to Naples* (1909); *Southern France* (1914); *Switzerland* (1922); *Tyrol and the Dolomites* (1927); The Blue Guides, *Muirhead's, Switzerland with Chamonix and the Italian Lakes* (1923); *Northern Italy* (1924); *The French Alps* (1926). There are also several volumes of "Climbers Guides," written by Sir W. M. Conway and W. A. B. Coolidge. Valuable information can be obtained from the publications (that date from 1863) of the various Alpine clubs—English, French, Swiss, German and Austrian, Austrian, Italian, etc. All the countries which include Alpine districts have now issued excellent official maps based on recent surveys.

The most important works on the Geology and Tectonics of the Alps, all of which contain bibliographies, maps, photographs and sections, are:—Alb. Heim, *Geologie der Schweiz* (1916–1922); R. Staub, *Der Bau der Alpen* (1924); L. Kober *Bau und Entstehung der Alpen* (1923) and L. W. Collet, *The Structure of the Alps* (1927); and of individual papers mention must be made of E. Argand, *Sur l'arc des Alpes Occidentales* (1916). For the question of the relation to other regions see E. Suess, *Das Antlitz der Erde* (1885, English trans. 1904); L. Kober, *Der Bau der Erde* (1921); E. Argand, *La Tectonique de l'Asie* (Congrès Géol. Internationale [1922]).

Recent detailed geological maps are published for many parts of the Alps (see L. W. Collet, *The Structure of the Alps*, 1927) and tectonic maps and sections are by E. Argand, *Les Nappes de Recouvrement des Alpes Occidentales* (1911) and R. Staub, *Tektonische Karte der Alpen* (1923), with sections (1925).

Important works on Glaciology are:—A. Penck and E. Brückner, *Die Alpen im Eiszeitalter* (1909); J. Bayer, *Der Mensch im Eiszeitalter* (1927); H. Gams and R. Nordhagen, *Postglaziale Klimaänderungen* (1923).

Works on Alpine Flora are:—H. Christ, *Das Pflanzenleben der Schweiz* (1882); R. von Wettstein, *Die Geschichte unserer Alpenflora* (1896); the best book of coloured plates is the *Atlas der Alpenflora* (5 vols. 2nd ed. 1897); Engler, *Die Pflanzenformationen, und die pflanzengeographische Gliederung der Alpenkette* (1901); Chodat and Pampanini, *Sur la distribution des plantes des alpes austro-orientales* (Geneva, 1902); Jerosch, *Geschichte und Herkunft der schweizerischen Alpenflora; eine Übersicht über den gegenwärtigen Stand der Frage* (1903); W. A. Clark, *Alpine Plants* (1907); Schröter, *Das Pflanzenleben der Alpen* (Zurich, 1908); H. Correvon and P. Robert, *La Flore Alpine* (1910); E. A. N. Arber, *Plant Life in Alpine Switzerland* (1911); G. Flemwell, *The Flower-Fields of Alpine Switzerland* (1911); H. Correvon, *The Alpine Flora* (1912); C. L. Maynard, *An Alpine Meadow* (1912); J. Hoffmann, *Alpine Flora* (1925); W. B. Wright, *Alpine Flowers and Rock Gardens* (1925).

The classic of Alpine Zoology is F. von Tschudi's *Das Tierleben der Alpenwelt*. See also zoological section, by K. W. von Dalla Torre, of *Anleitung zu wissenschaftlichen Beobachtungen auf Alpenreisen*; V. Fatio, *Faune des vertébrés de la Suisse* (5 vols., 1869–1904); F. Zschokke, *Die Tierwelt der Hochgebirgsseen* (1900); also C. Zeller, *Alpentiere im Wechsel der Zeit* (1892). (J. I. P.)

ALPS, AUSTRALIAN, term applied somewhat loosely to the mountain massif which occupies the south-easternmost corner of Australia (eastern Victoria and south-eastern New South Wales). In a more localized sense it is applied to the higher ranges which stretch across the Victoria–New South Wales boundary and form the water-shed between the upper Murray system (Ovens, Mitta-Mitta, Indi rivers) on the north-west, and the streams (Tambo, Snowy river) flowing to the Pacific on the south-east, the upper Murrumbidgee, owing probably to events of tectonic history, partaking of both characters. The term "Alps" as applied to these mountains denotes their general characteristics as massive and seasonally snow-clad highlands rather than their special structural features. In this latter sense they are not "Alpine" mountains, being a powerfully developed "block" massif composed of elevated "horsts" and down-faulted areas (Senkungsfelder). This faulting affected an area of comparatively homogeneous topography—a peneplanated surface developed on granitic and Palaeozoic rocks—and diversified it into a series of massive flattish uplands and comparatively roomy depressions. These movements, continuing into late Tertiary times or later (late Pliocene–early Pleistocene) were followed by a local glaciation (Pleistocene–Kosciusko ice age) which further emphasized the flatness of the summit topography. The result is an upper surface of broad undulating highlands upon which the highest elevations (Kosciusko, 7,340ft.; a series of heights variously named: 5,000–6,500ft.) are not distinctly remarkable. The areas of depression (e.g., Monaro) are occupied by the headwaters of streams, which, owing to the spasmodic nature of the uplifts, have worked out characteristic "valley-in-valley" forms. There are also evidences of extensive river piracy.

The highlands are snow-clad in winter, though the tree-line lies at 5,000ft. and the area of Alpine flora is small. The rocks of these highlands are extensively, if not richly, mineralized and a good deal of mining mainly in small and scattered workings (e.g., Kiandra [alt. 4,640ft.], the highest settlement in Australia; Araluen) is carried on. The valleys and basins have considerable possibilities for closer agricultural settlement, but they and the lower uplands have so far been utilized mainly for pastoral purposes. There are numerous fine sheep-stations and in the Monaro uplands in particular (Cooma: alt. 2,657 ft.; pop. c. 3,000) are good cattle, grain and fruit lands. The chief importance, however, of the Australian Alps is as a source of water-supply. The snows feed perennially the streams of south-east Australia and are thus the basis of the present and potential development of irrigation agriculture, and of inland navigation, in the adjoining areas. Physical features also—particularly the presence of long narrow valleys cut in hard rocks—have facilitated water conservation on a large scale and form thus a foundation of permanent wealth.

In addition, this area is becoming increasingly a national playground and health-resort. Kosciusko is approached chiefly from the Monaro side (Cooma is a growing tourist centre), and the cor-

responding Victorian district is the Wangaratta-Bright-Mt. Buffalo tourist route.

ALPUJARRAS, THE, a district of southern Spain, in the provinces of Granada and Almería, from the Nevada to the coast between Motril and Almería. A structural depression between the Nevada and the coastal sierras contains the mid-courses of Nevada streams which have wild gorges above and below. These mid-courses are in beautiful fertile secluded valleys with villages often on ledges overhanging the streams, and to them the name Alpujarras is often exclusively applied. The vegetation ranges from sugar cane and palm in the valleys to Alpine flora on the heights through belts of orange, lemon and fig, of vine and olive, of chestnut and walnut and of oak and has no parallel in Europe.

The treaty of Granada assigned the district to Boabdil but it was not observed. The descendants of the Moors were removed in 1570 after long rebellions, and colonists, especially from Estremadura, came in. An Alpujarras militia for coast-defence was dependent on Veléz-Málaga. Ugijar was formerly the capital, Orgiba is another town; Lanjarón has a castle and chalybeate baths, Trevelez is the highest village.

See *Boletín de la Real Soc. Geogr. Madrid*, xlviii., 1906 pp. 426-99.

'ALQAMA IBN 'ABADA, generally known as **'ALQAMA AL-FAHL**, an Arabian poet of the tribe Tamīm, who flourished in the second half of the 6th century. His diwān consists of three qasidas (elegies) and 11 fragments. Asma' i considered three of the poems genuine.

The poems were edited by A. Socin with Latin translation as *Die Gedichte des 'Alkama Alfahl* (Leipzig, 1867), and are contained in W. Ahlwardt's *The Diwans of the six ancient Arabic Poets* (1870); cf. W. Ahlwardt's *Bemerkungen über die Aechtheit der alten arabischen Gedichte* (Greifswald, 1872), pp. 65-71 and 146-168.

ALSACE, EARLY OPERATIONS IN: see FRONTIERS, BATTLES OF THE.

ALSACE-LORRAINE, a territory which has been the subject of many disputes and which was largely responsible for the difficulties that led up to the wars of 1870-71 and 1914-18. Alsace is essentially the part of the great trough between the Vosges and the Black Forest which lies west of the Rhine, but it extends to the highest Vosges. Lorraine stretches between the Vosges and the Ardennes and includes a portion which remained French 1871-1914, and the north-eastern zone, which was in German possession during that period. There is no doubt that these important regions are in many respects transitional between France and Germany in culture, and in parts the dialect is Germanic while in others it is French. If a general statement is possible it is that Alsace is more German and Lorraine more French in speech, but the influence of politics and education makes a true judgment difficult. The regions are further discussed geographically under the names of the French departments, Haut-Rhin, Bas-Rhin (parts of Alsace) and Moselle, Meurthe et Moselle, Meuse, Vosges (parts of Lorraine). Haut-Rhin, Bas-Rhin and Moselle represent the land returned to France after 1918.

In October, 1928, M. Poincaré opened the new railway tunnel through the Vosges, reducing the rail distance between St. Dié and Strasbourg from 105 m. to 62 m.

See P. Vidal de la Blache, *La France de L'Est* (1918).

HISTORY

The term Alsace-Lorraine came into use only after the Peace of Frankfurt (May 1871). It was used to describe a hybrid creation, artificially forged by Bismarck out of the whole of Alsace and part of Lorraine; both provinces having been annexed from France. These two countries (from earliest times a part of Belgian Gaul) had hitherto lived a separate existence since the 5th century when, after 450 years of Roman domination and civilization, they were invaded by Germans (principally Alemanni), who had crossed the Rhine.

Lorraine.—Since her true history began, Lorraine had preserved her Latin-speaking population through the greater part of her territory; the German barbarians having established themselves only in the north-east, on the borders of the Moselle, the Sarre and the Nied, beyond a line running approximately from

Thionville to Sarrebourg. Besides its dependency, together with the county (later duchy) of Bar, and the three bishoprics of Metz, Toul and Verdun, Lorraine included the duchy of that name, the capital of which was at Nancy. Long disputed between the kingdom of France and the Germanic Holy Roman empire, these countries, which, after the Frank era (511-925), had belonged to Germany, *de facto* up to the end of the 13th century, and nominally up to the 16th century, had retained a real independence, under their dukes, until the 18th century; at which epoch, after the rule of the dethroned king of Poland, Stanislaus Augustus, father-in-law of Louis XV., king of France, Lorraine was reunited to the French crown in 1766.

Alsace.—During this time Alsace had become a purely Germanic country in consequence of the invasions and penetration of the Alemanni in the 5th and 6th centuries. Its civilization and religion had, however, come from the West—brought by the Merovingian kings and Irish, Scottish and Anglo-Saxon monks. After Charlemagne, it was at first a frontier country (bi-lingual Oath of Strasbourg, 842; Treaty of Verdun, 843, constituting "Lotharingia" a buffer state between France and Germany). Then, in the period of decadence of the Frank monarchy and of the constitution of the Germanic empire, which in 962 became the Holy Roman empire, it formed part of the Germanic world (as a portion of the duchy of Suabia or Alamania) from 870 or 887 to 1648, or seven and a half centuries.

During this long period Alsace enjoyed, actually, a large degree of independence. For a hundred years only (the 12th century) the imperial house of Hohenstaufen was popular in the provinces, during which time the emperors visited the country more than once; but this popularity was due to the municipal franchises granted by them to the cities. There was an intense municipal activity throughout the middle ages, witnessed by the league of the ten free "Imperial" cities, or "Decapolis." The representatives of the emperor (imperial bailiwick and subordinate bailiffs) enjoyed no real influence, and were frequently defied by the barons of fortified towns situated on the escarpments of the Vosges. But the clergy exercised a strong authority in a country which is deeply religious (Saint Odil is the patron saint of Alsace), and the bishops of Strasbourg and Basle were the real masters of lower and upper Alsace.

In the 14th and 15th centuries, the Habsburgs of Vienna, the successors of the Hohenstaufen in the imperial dignity, exercised only a purely nominal power over Alsace. In the 16th century the Reformation was at first very successful throughout the country. In the 17th century the religious Thirty Years War brought thither the Protestant Swedes, followed by their ally, the king of France, who annexed the country under the Treaty of Westphalia (1648). It was thus as ally of the Protestants of Germany and as adversary of the imperial unity that the king of France conquered Alsace.

The treaties of Westphalia had left the ten imperial free cities and the rights of the German princes holding lands in Alsace outside the authority of the French king. The former were annexed by Louis XIV. in peace-time (Chambers of Reunion, 1681), while the latter were suppressed by the French Revolution.

The *ancien régime* had respected the *status quo* in Alsace, and left Protestantism undisturbed, even after the revocation of the Edict of Nantes. Alsatian manners, customs and tongue had, as a rule, been preserved. The Revolution, which was hailed with enthusiasm throughout the country, popularized the French language, which was looked on as the "language of liberty." The festivals of the "Federation of the Rhine," or "Confederation of Strasbourg," June 11-13, 1790 (oath of the Butchers' Field), laid the foundations of that Alsace which henceforward, like Lorraine,

ALSACE-LORRAINE, IN
THE TRADITIONAL ALSA-
TIAN COSTUME

was to partake of the life of France until the day when Bismarck annexed the whole of Alsace and part of Lorraine, to "form a glacis" against France. The German law of June 3, 1871, declared these territories imperial territories (Reichsland). On that day Alsace-Lorraine was born.

THE GERMAN PERIOD

Its history under German domination falls into three periods:

(1) **1871-90: the Period of Organization.**—At first (until the constitution of July 4, 1879) Alsace-Lorraine was organized under decrees issued in Berlin and applied by an *Oberpräsident*; after 1879, by an imperial representative with the powers of a chancellor, or *statthalter* (Manteuffel, later Prince Hohenlohe-Schilling), residing at Strasbourg and assisted by two under-secretaries of state. The administration was organized by the imperial rescript of Dec. 30, 1871, under para. 10 of which the head of the administration received dictatorial powers. The territory was divided into three administrative districts: Upper Alsace, Lower Alsace, and Lorraine. A formidable army of occupation was maintained, but an autonomous network of railways helped to develop Strasbourg's commercial life. In 1874, an electoral assembly, or *Landesausschuss*, was granted, to sit at Strasbourg. Nevertheless, the inhabitants continued to protest. Hohenlohe's severities, and especially his system of passports, strengthened the opposition. The provinces longed for the arrival of the French, in whom the spirit of revenge was kept alive by such frontier incidents as the Schnaebelé in 1887, by the "Boulangiste" movement and Déroulède's (*q.v.*) "*Ligue des patriotes*." (See also FRANCE: *History*). But in France, at the general elections of 1889, the Republican Party, the advocates of peace, triumphed, while in Germany Bismarck was dismissed in March 1890 by the young emperor, William II., who immediately inaugurated a new policy, abolishing passports, and allowing greater liberality in the granting of *permis de séjour*.

(2) **1890-1902.**—The second period was one of calm, of economic development and of material prosperity. The inhabitants of the Reichsland ceased to wage against the empire a necessarily barren opposition; and at the Reichstag elections of 1890 not a single irreconcilable was left. The "autonomist" party itself disappeared in the elections of 1898. The chief party was the Clerical; beside this, there were the Socialists, and even some German *immigrés*. The new *statthalter*, Hohenlohe-Langenbourg (1894), an oldish man, appointed native under-secretaries (Zorn de Bulach, Pétri). This was the epoch when the German emperor was coquetting with France. The Alsations believed it possible to show loyalty to the empire without failing in their allegiance to France. They cajoled their masters (for instance by the reconstruction of Hoh-Königsberg, 1901-02), but claimed in return liberties equal to those enjoyed by other Germans. These the German Government refused to grant until they had become more than loyal subjects—enthusiastic Germans. This was too much to ask. Meanwhile, the Alsations complained that they were left with "secondary rights of citizenship."

(3) **1902-18.**—The third period began with an attempt to form a constitution. William II., through the chancellor, von Bülow, proposed, by rescript of May 9, 1902, the suppression of the notorious "dictatorship paragraph" (para. 10 of the rescript of Dec. 30, 1871); and this was abolished on June 9. Now that the press enjoyed more liberty, its power rapidly developed. The presiding minister, M. de Koeller, was able, thanks to his jovial frankness, to direct the *Landesausschuss* as he would. "Protests" had ceased completely. The process of Germanization made rapid progress in the country districts, chiefly owing to the bad impression made on the Alsatian Clerical Party by the campaign against the Catholic Church initiated by the French Government. The Clerical Party, the strongest numerically of all the Alsatian parties, now formed part of the German Centre Party. The best minds in Alsace, however, worked particularly through the medium of the Alsatian theatre, the *Revue Alsacienne*, and lectures were delivered in French to save French culture from extinction, while the desire for a liberal constitution grew stronger every day among the masses.

While the semi-official press, such as the *Strassburger Post*—the mouthpiece of Pan-Germanism—denounced and maligned everything connected with France, provoking ironical and biting retorts from the Alsatian caricaturists, the Government, to give a semblance of satisfaction to Alsatian opinion, passed the constitution of May 31, 1911, through the Reichstag. This established a diet (*Landtag*) of two chambers, which cancelled each others' activities, while the upper house was entirely subservient to the German Government; the *statthalter* was not responsible to them. To counter the "*Union nationale alsacienne-lorraine*," the Government supported the Socialists and the Centre Party at the elections to the *Landesausschuss* of Oct. 1911; but the new house although elected with the support of the Government, was soon in conflict with it, on account of the excesses of the Pan-Germanists. A vote of censure was passed upon the Government for their conduct in the notorious incident of Grafenstaden (April 1912)—when the Government demanded the dismissal of the director of the locomotive works on the ground of French intrigues. Germany's preparations for war rendered the German army in Alsace-Lorraine more insolent than ever and the Zabern incident (1913-14), which amounted to an organized militarist insult to things Alsatian, resulted in further votes of censure and finally in the formation of the *Ligue pour la défense de l'Alsace-Lorraine* (March 1914).

In spite of the continuous and partially successful efforts of Germany from 1871 to 1914 to assimilate Alsace-Lorraine, the divorce between the Alsatian and the German mentality was thus more complete than ever on the eve of the World War. At its very outset, some 1,000 suspected persons, whose names were on a black list, were arrested. When the German reserve troops entered Alsace to attack France, their officers warned their men that on crossing the Rhine they would enter "hostile territory." At the end of the first year of the War, the German Government, confident of victory, were deciding on the partition of Alsace-Lorraine between Bavaria and Prussia immediately on the conclusion of peace, deportations and the confiscation of landed property on the widest scale, and colonization by large numbers of ex-soldiers of Prussian stock. During the four years of the War, the inhabitants of Alsace and Lorraine lived under a reign of terror; they were forbidden to speak French in the streets, numbers were denounced by the gendarmerie, and many deported to Germany; 19,000 persons were still in exile in 1918.

In Sept. and Oct. 1918, the evacuation of Alsace was anxiously awaited, and it was rumoured that the Germans in their rage would leave no stone upon another. Thus, when the collapse of Germany came, the concessions extorted from the Germans by the fear of reprisals in Oct. 1918 could not prevent the long-pent up feelings of the population from finding enthusiastic outlet, and the French were everywhere welcomed as liberators.

POST-WAR PROBLEMS

The previous history of Alsace-Lorraine explains the difficulties met by France in this country since the armistice. Many institutions had been introduced by the Germans during the half-century of their occupation—the land survey, the German civil code, social legislation, etc.—and the population had grown accustomed to German administration, which in certain respects was far in advance of the French. Certain urgent problems arose immediately after the armistice, and these were solved by France in the most liberal and generous spirit; the German mark was accepted at the exchange rate of 1fr. 25c.; the railways, which had once formed an integral part of the French *chemin de fer de l'est*, were maintained as an autonomous system, etc.

France is a unified and centralized state, although of democratic spirit and admitting freedom of discussion. Germany was an aristocratic and authoritative state, but its constitution was federal. The Alsations, moreover, being fundamentally democratic and impatient of authority, like the true French, had got into the habit under the German rule of looking to Strasbourg rather than to Berlin. These habits have inclined them to resist a complete assimilation with the rest of France, despite the obvious kinship of the two mentalities. To satisfy the peoples of the

recovered provinces, the French Government thought it better at first not to hurry things overmuch; a *Haut-Commissariat* was therefore established at Strasbourg, followed by a *Commissariat général*, a provisional arrangement that was maintained until 1925, the successive commissioners being Maringer, Millerand, Alapetite and Cacaud. They were assisted by a *conseil régional* composed of native notabilities. Since 1925 there has been a Government department for Alsace-Lorraine at Paris, consisting of an under-secretary of state and an advisory council. These changes, although inevitable—they could, indeed, have been foreseen from the beginning—were destined to afford a pretext for malcontent agitation. A new political party was formed under the name of "autonomists" (manifesto of the *Heimattbund*, June 1926). Emboldened by the passivity of the French authorities, who have respected, perhaps too scrupulously, liberty of opinion, this party is supported by all the German immigrants who became French citizens under the Treaty of Versailles, and also by propaganda from beyond the Rhine. Already it aims at the separation of Alsace-Lorraine from France. In 1926 it demanded autonomy "*dans le cadre de la France*," but in 1927 this no longer satisfied it. Its manifesto of Sept. 1927 showed that it had ceased to be autonomist and become separatist.

Backed by the clerical press and by the Communists, the Autonomist Party set itself to oppose France by every means in its power. In 1928 the arrest of the chiefs of the party on a charge of plotting against the state gave them the opportunity of posing before the electorate as martyrs—which secured their election in April to the *Chambre des députés*. The trial which followed at Colmar in May, and which ended with the condemnation of the principal offenders further excited popular passion for some considerable time.

Two burning questions make this agitation formidable—that of religion and that of education. As all its history demonstrates, religion is almost as strong a factor in Alsace as democracy. In France, although complete freedom of conscience is assured, yet the neutrality of the state in religious matters is absolute. The Germans, however, cast their net round both the Catholic and Protestant clergy; intending priests and pastors were obliged to attend German universities. The denominational schools were maintained. Modern France, therefore, with its lay schools and its separation of Church and State, was suspect in the eyes of the clericals of Alsace and Lorraine. The French Government wisely decided to maintain the existing state of things in the recovered territories; and when, as sometimes happens, it establishes here and there an "interdenominational" school (different from a lay school) it is in no way hostile to the habits of the country, and only acts as it does at the request of the population interested. This does not, however, prevent the Clerical Party (the *Union populaire républicaine*) from uttering strongly worded protests; so that it has been suspected in many quarters of secret complicity with the autonomists.

The question of education bulks equally large. While Germany forbade the teaching of French, France has retained that of German. There are protests, however, against a system which forces a German-speaking population to devote more time to French than to German. Against this it is urged that it is natural that France should wish her citizens to understand the language of their country. Moreover, the Government has made certain concessions (Sept. 1927).

Behind all these divergences of view lies, of course, the opposition of the two civilizations. But the two civilizations should rather supplement each other, and the solution of this question is easy enough if history be consulted, and with it the secret feelings of the immense majority of the inhabitants of Alsace-Lorraine. From the remotest times, Alsace has formed the arena in which two civilizations have either met or replaced one another. Goethe studied, and Pasteur taught, at Strasbourg. Autonomy for Alsace-Lorraine is totally impracticable. The chief ambitions of its people are first to have done, once and for all, with swinging backwards and forwards between France and Germany; secondly, to act as a connecting link and as the messengers of peace between the two countries. To do this they must learn to know France.

But this requires time.

ALSATIA (the old French province of Alsace), long a "debatable ground" between France and Germany, and hence a name applied in the 17th century to the district of Whitefriars, between the Thames and Fleet street, in London, which gave sanctuary (*q.v.*) to debtors and criminals. The privileges were abolished in 1697.

ALSBERG, CARL LUCAS (1877—), American biochemist, was born in New York city, on April 2, 1877. He graduated at Columbia university in 1896 and from the College of Physicians and Surgeons in 1900. Following three years' study in 1900-03 at the universities of Berlin and Strassburg, Germany, he was an assistant and instructor in biological chemistry in Harvard university until 1908. From 1908 to 1912 he was chemical biologist in the bureau of plant industry and from 1912 to 1920 he was chief of the bureau of chemistry in the U.S. Department of Agriculture. In 1920 he was made director of the Stanford Food Research Institute, Stanford university, California. His researches include investigations on the biology and toxicology of moulds, cyanogenesis in plants, poisonous plants, phosphoric acid metabolism, nucleic acids, proteins, cystinuria, enzymes and the chemistry of foods.

ALSEN, a Danish island in the Baltic, off the coast of Slesvig, in the Little Belt. It was Danish property until 1864 when it was incorporated with Germany. It was of strategic importance as it guarded an approach from the North sea to the Baltic. After 1919 it was again in Danish hands. The island is fertile and well wooded and Sønderborg, the capital, has a good harbour. Most of the inhabitants speak Danish. Area of island 105 sq.m.

ALSIETINUS LACUS (mod. LAGO DI MARTIGNANO), small lake, south Etruria, 15m. due N.N.W. of Rome, in an extinct crater. Augustus drew from it the Aqua Alsietina; the water was hardly fit to drink, and was mainly intended to supply his *naumachia* (lake made for a sham naval battle) at Rome, near S. Francesco a Ripa, on the right bank of the Tiber. The aqueduct, mainly subterranean, is practically untraced. Frontinus tells us that it received water from the lake of Bracciano near Careiae (Galera); and an inscription relating to it has been found in this district, while the only known remains of the channel were found on the Janiculum in 1927.

ALSIKE, also called Swedish clover, the name by which *Trifolium hybridum* is known to farmers and agriculturists. It is a perennial form resembling the white or Dutch clover (*T. repens*) and, like it, has white or rosy flowers. Alsike was introduced into Great Britain from south Sweden in 1834. It has also become widely naturalized in North America. In the eastern United States and in south-eastern Canada it is an important agricultural clover. Although alsike has been regarded as intermediate between the white species *T. repens* and the red species *T. pratense*, it is not a hybrid, but a distinct species. (See CLOVER.)

ALSIUM (mod. PALO), ancient town, Etruria, on the Via Aurelia, about 22m. from Rome. It was one of the oldest cities of Etruria, colonized by Rome in 247 B.C., but was of importance only as a resort of wealthy Romans, many of whom (*e.g.*, Pompey and the Antonine emperors) had villas there, considerable remains of which exist. The mediaeval castle belongs to the Odiscalchi family.

ALSOP, VINCENT (c. 1630-1703), English Nonconformist divine, was ejected from his living under the Act of Uniformity in 1662. He had a great reputation as a pamphleteer in his day. Even with Dr. Goodman and Dr. Stillingfleet as opponents he held his own. His *Mischief of Impositions* (1680), in answer to Stillingfleet's *Mischief of Separation*, and his *Melius Inquirendum* (1679), in answer to Goodman's *Compassionate Inquiry*, remain historical landmarks in the history of Nonconformity.

See Wood's *Athenae* (Bliss) iv. 106; Calamy's *Life of Baxter*, ii. 487; Wilson's *History and Ant. of Dissenting Churches*, iv. 63-66.

ALSTED, JOHANN HEINRICH (1588–1638), German Protestant divine. He was sometime professor of philosophy and theology at Herborn, in Nassau, and afterwards at Weissenburg in Transylvania, where he remained till his death in 1638. He was a marvellously prolific writer. His *Encyclopaedia* (1630), the most considerable of the earlier works of that class, was long held in high estimation.

ALSTON, market town, Cumberland, England, on a branch of the L.N.E.R. from Haltwhistle. Population of parish (Alston with Garrigill) (1931) 2,678. It lies in the uppermost part of the valley of the South Tyne, among the high bleak moors of the Pennines. Copper and blende are found, and there are limestone quarries. The mines of argentiferous lead, belonging to Greenwich hospital, London, were formerly of great value, and it was in order that royalties on the Alston lead mines and on those elsewhere in the county might be jointly collected that the parish was first included within the borders of Cumberland in the 18th century. As many as 119 lead mines were worked in the parish in 1768, but the supply of metal has been almost exhausted. Coal is worked in the neighbourhood. Thread and flannels are also made. Whitley castle, 2m. N., was a Roman fort, the original name of which is not known, guarding the road which ran along the South Tyne valley and over the Pennines. It has no connection with Alston itself.

ALSTONITE, a member of the aragonite group of minerals. It consists of an isomorphous mixture of calcium and barium carbonates in various proportions (Ca,BaCO_3), and thus differs chemically from barytocalcite (*q.v.*) which is a double salt of these carbonates in equal molecular proportions. Being isomorphous with aragonite, it crystallizes in the orthorhombic system, but simple crystals are not known. The crystals are invariably complex twins and have the form of doubly terminated pseudo-hexagonal pyramids, like those of witherite but more acute. The crystals are translucent and white, sometimes with a shade of pink. Sp. gr. 3.706; hardness 4–4½. The mineral has been found at only three localities, all of which are in the north of England. It takes its name from Alston in Cumberland, where it occurs in veins of lead ore.

ALSTRÖMER, JONAS (1685–1761), pioneer of Swedish industrialism, was born at Alingsås in Vestergötland, Jan. 7, 1685. He left his native village at an early age, and in 1707 became clerk to Alberg, a merchant of Stockholm, whom he accompanied to London. After carrying on business for three years, Alberg failed, and Alströmer (who changed his name from Alström on receiving letters of nobility) engaged in the business of shipbroker on his own account. He returned to Alingsås, and in 1724 established a woollen factory there. After preliminary difficulties it became a very profitable business. He next established a sugar refinery at Gothenburg, introduced improvements in the cultivation of potatoes and of plants suitable for dyeing, and directed attention to improved methods in shipbuilding, tanning and the manufacture of cutlery. But his most successful undertaking was the importation of sheep from England, Spain and Angora. He died June 2, 1761, leaving several works on practical industrial subjects.

ALT, ALTISSIMO. In music, the notes of the octave beginning with the G above the treble stave are said to be "in alt" and those of the succeeding octave "in altissimo," although by some the F instead of the G is taken as the beginning of the higher octave. The same notes are also indicated by the employment of italic type followed by two and three strokes respectively, e.g., *g''* and *g'''*.

ALTAI (in Mongolian *Altai-nula*, the "Mountains of Gold"), a term used with various significations. The *Altai region*, in west Siberia and Mongolia, is similar in character to the Alps, but covers a much greater area. It extends from the river Irtysh and the Dzungarian depression (46°–47°N.) northwards to the Siberian railway and to the Sayan mountains. The backbone of the region is the Sailughem mountains (Silyughema or Kolyvan Altai), which stretch north-eastwards from 49°N. and 86°E. towards the west end of the Sayan mountains (51° 60'N. and 89°E.). Their mean elevation is 5,000–5,500ft. The snow-line

runs at 6,700ft. on the northern versant and at 7,800ft. on the southern, the rugged peaks standing 3,200ft. above it. Passes are few and difficult, the chief being Ulan-daban at 9,275ft. (9,445ft. according to Kozlov) and Chapchan-daban, at 10,555ft., in the south and north respectively. On the east and south-east this range is flanked by the great plateau of Mongolia, the transition being effected gradually by means of several minor plateaus, such as Ukök (7,800ft.), Chuya (6,000ft.), Kendykty (8,200ft.), Kak (8,270ft.), Suok (8,500ft.) and Juvlu-kul (7,900ft.). This region, which is not accurately known, is studded with large lakes, e.g., Ubsa-nor (2,370ft. above sea-level), Kirghiz-nor, Durga-nor and Kobdo-nor (3,840ft.), and crossed by mountain ranges, the principal being the Tannu-ola, roughly parallel with the Sayan mountains as far east as the Kosso-gol (100°–101°E.), and the Khan-khu mountains, also stretching west to east.

The *Altai proper* (the Ek-tagh, Mongolian Altai, Great Altai or Southern Altai) likewise extend in two twin parallel chains eastwards as far as 99°, if not farther. The Ek-tagh, which separates the Kobdo basin (north) from the Irtysh basin (south), is a true border-range, in that it rises in a steep and lofty escarpment from the Dzungarian depression (1,550 to 3,000ft.), but descends on the north by a relatively short slope to the plateau (4,000–5,500ft.) of north-western Mongolia. East of 94° the range is continued by a double series of quite distinct chains. The southern chain bears the names of Karaadzirga and Burkhan-ola, and terminates in about 99°; but the northern range, the principal names of which are Artsi-bogdo and Saikhat, extends probably most of the way to the great northward bend of the Hwang-ho round the desert of Ordos. Whereas the western Ek-tagh Altai rises above the snow-line and is destitute of timber, the eastern double ranges barely touch the snow-line and are clothed with thick forests to an altitude of 6,250ft. The slopes of these chains are inhabited principally by nomad Kirghiz.

The north-western and northern slopes of the Sailughem mountains are extremely steep and very difficult of access. On this side lies the culminating summit of the range, the double-headed Byelukha, whose summits reach 14,890 and 14,560ft. respectively, and give rise to several glaciers. Here also are the Kuitun (12,000ft.) and several other lofty peaks. There are numerous spurs, striking in all directions to the lowlands of Tomsk, but their mutual relations are not well known. Such are the Chuya alps (average altitude 9,000ft., with summits from 11,500 to 12,000ft., and at least ten glaciers on their northern slope); the Katun alps (mean elevation about 10,000ft. and mostly snow-clad); the Kholzun range; the Korgon (6,300 to 7,600ft.), Talitsk and Selitsk ranges; the Tigeretsk alps, and so on. Several secondary plateaus of lower altitude are also distinguished. The River Katun begins in a wild gorge on the south-west slope of Byelukha; then pierces the Katun alps, and enters a wider valley, at an altitude of from 2,000 to 3,500ft., which it follows until it joins the River Biya, to form the River Ob. The River Charysh has the Korgon and Tigeretsk alps on one side and the Talitsk and Bashalatsk alps on the other, and its valley, like the others, is very fertile. Farther west the valleys of the Uba, the Ulba and the Bukhtarma open south-westwards towards the Irtysh. The lower part of the first, like the lower valley of the Charysh, is thickly populated; in the valley of the Ulba is the Riddersk mine, at the foot of the Ivanovsk peak (6,770ft.). The valley of the Bukhtarma also has its origin at the foot of the Byelukha and the Kuitun peaks, and it falls some 5,000ft. in less than 200m. to the Bukhtarma fortress (1,130ft.). Its upper parts abound in glaciers, the best known of which is the Berel, which comes down from the Byelukha. On the northern side of the range which separates the upper Bukhtarma from the upper Katun is the Katun glacier, in which the Katun river rises. The middle and lower parts of the Bukhtarma valley have been colonized since the 18th century by runaway Russian peasants who created there a free republic on Chinese territory; and after this part of the valley was annexed to Russia, in 1869, it was rapidly colonized. The high valleys farther north, on the same western face of the Sailughem range, are little known, their only

visitors being Kirghiz shepherds. Those of Bashkaus, Chulyshman, and Chulcha, all three leading to Lake Teletskoye (length, 48m.; max. width, 3m.; altitude, 1,700ft.; area, 87sq.m.; max. depth, 1,020ft.; mean depth, 660ft.), are only inhabited by nomad Telenghites or Teleuts. The shores of the lake rise almost sheer to over 6,000ft. and are too wild to accommodate a numerous population. From this lake issues the Biya, which joins the Katun at Biysk. Farther north the Altai highlands are continued in the Kuznetsk district, which has a slightly different geological aspect, but still belongs to the Altai system. But the River Abakan, which rises on the west of the Sayan mountains, belongs to the system of the Yenisei. The Kuznetsk Ala-tau range, on the left bank of the Abakan, runs north-east while a complex of imperfectly mapped mountains (Chukchut, Salair, Abakan) fills up the country northwards towards the Siberian railway and westwards towards the Ob. The Tom and its numerous tributaries rise on the northern slopes of the Kuznetsk Ala-tau, and their fertile valleys are occupied by a dense Russian population, the centre of which is Kuznetsk, on the Tom.

Geology.—The Altai mountains consist of two distinct elements which differ considerably in geological formation. The Mongolian, or Great Altai, consists essentially of Archaean rocks (gneisses, etc.), in which there is no folding of Hercynian or Alpine age, but the strike of the rocks is independent of the direction, determined by fault fractures, of the chains. The region forms a horst. In the Russian Altai we find various Archaean schists with Palaeozoic rocks, predominantly limestones with Devonian and Carboniferous fossils. They were folded during the Hercynian period, the general trend of the folds being north-north-east. Of the same age as the folding are intrusions of granitic and other igneous bodies with which are associated the famous ore deposits.

Flora.—The flora of the Altai is rich and very beautiful. Up to a level of 1,000ft. on the northern and 2,000ft. on the southern slopes, plant life belongs to the European flora, which extends into Siberia as far as the Yenisei. The steppe flora penetrates into the mountains, ascending some 1,100–1,200ft., and in sheltered valleys even up to 5,500ft., when it comes into contact with the purely alpine flora. Tree vegetation, which reaches up as high as 6,500 and 8,150ft., the latter limit on the north and west consists of magnificent forests of birch, poplar, aspen and Coniferae, such as *P. cembra*, though the fir is not found above 2,500ft., while the meadows are abundantly clothed with brightly-coloured, typical assortments of herbaceous plants. The alpine meadows, which have many species in common with the European Alps, have also a number of their own peculiar Altaian species.

For population, administrative divisions and mining activities, etc., see SIBERIAN AREA.

ALTAIR, the brightest star in the constellation Aquila (*q.v.*), and, on this account, also known as α Aquilae. It is the middle member of the group β , α , γ in the constellation, and is of the first magnitude, being one of the nearest stars. Its distance from the solar system is four parsecs or 14 light-years. (See LIGHT-YEAR.) It is a globe giving out 12 times as much light as the sun.

ALTAMURA, Apulia, Italy, province of Bari, 28m. S.W. of the city Bari, and 56m. by rail via Gioia del Colle. Pop. (1921) 26,877 (town), 27,155 (commune). It possesses a fine Romanesque cathedral begun in 1232 and restored in 1330 and 1543, the portal being especially remarkable. It is one of the four Palatine churches of Apulia. The mediaeval walls, erected by the emperor Frederick II., rest upon the walls of a pre-Roman city of unknown name. There is some trade in wool.

ALTAR, a base or pedestal used for sacrifice or prayer to a deity.

Mesopotamia.—Altars are found from the earliest times in the remains of Babylonian cities; the oldest are square erections of sun-dried bricks. In Assyrian mounds limestone and alabaster are the chief material. They are of varying form; an altar shown in a relief at Khorsabad has stepped battlements, corresponding to the Hebrew "altar-horns." An altar also from Khorsabad (now in the British Museum) has a circular table and a solid base, triangular in plan, with pilasters ornamented with animals' paws at the

angles. An 8th century B.C. altar from Nimrûd (also in the British Museum) is a rectangular block with cylindrical rolls at the ends. These altars are 2ft. to 3ft. high. According to Herodotus (i. 183) the great altars of Babylonia were made of gold.

Egypt.—In Egypt altars took the form of a truncated cone or of a cubical block of polished granite or of basalt, with one or more basin-like depressions (with drainage channels) in the upper surface for receiving libations. The surface was plain, inscribed with dedicatory or other legends, or adorned with symbolical carving.

Palestine.—Recent excavations, especially at Gezer, have shown that the earliest altars, or rather sacrifice hearths, in Palestine, were circular spaces marked out by small stones set on end. At Gezer a pre-Semitic place of worship was found in which three such hearths stood together, and drained into a cave which may reasonably be supposed to have been regarded as the residence of the divinity. These circular hearths persisted into the Canaanite period, but were ultimately superseded by the Semitic developments. To the primitive nomadic Semite the presence of the divinity was indicated by springs, shady trees, remarkable rocks and other landmarks; from this conception grew the theory that a *numen* might be induced to take up an abode in an artificial heap of stones, or a pillar set upright for the purpose. The blood of the

THE CATHEDRAL, ALTAMURA, BUILT IN THE 13TH CENTURY
Altamura, an ancient town of Italy situated in fertile farm country at the foot of the Apennines, is famous locally for its fairs

victim was poured over the stone as an offering to the divinity dwelling within it; and the stone came finally to be used as a table on which the victim was to be burned.

A very remarkable altar, at present unique, was found at Taanach by the Austrian excavators. It is pyramidal in shape, and the surface is ornamented with human-headed animals in relief. This, like the earliest Babylonian altars, is of baked earth. These primitive altars were of the simplest possible description—in accordance with the regulation preserved in Exod. xx. 24–26, that *in every place where Yahweh records his name an altar of earth*

or of unhewn stone, without steps or other ornamentation, shall be erected.

The priestly regulations affecting altars are of a very elaborate nature, and are framed with a single eye to the essential theory of later Hebrew worship—the centralization of all worship at one shrine. These recognize two altars, which by the authors of this portion of the Pentateuch are placed in the tabernacle in the wilderness.

The first, that for burnt-offering, was in the centre of the court of the tabernacle, of acacia wood, 3 cubits high and 5 square. It was covered with copper, was provided with "horns" at the corners, hollow in the middle, and with rings on the sides into which the staves for its transportation could be run (Exod. xxvii. 1–8). The altar of the Solomonic temple is on similar lines, but much larger. It is now generally recognized that the description of the tabernacle altar is intended to provide a precedent for this vast structure, which would otherwise be inconsistent with the traditional view of the simple Hebrew altars. In the second temple a new altar was built after the fashion of the former (I. Macc. iv. 47) of "whole stones from the mountain." In Herod's temple the altar was again built after the same model. It is described by Josephus (v. 5, 6) as 15 cubits high and 50 cubits square, with angle horns, and with an "insensible acclivity" leading up to it (a device to evade the pre-Deuteronomic regulation about steps). It was made without any use of iron, and no iron tool was ever allowed to touch it. The blood and refuse were discharged through a drain into the brook Kedron; this drain probably still remains, in the *Bir-el-Arwah*, under the "Dome of the Rock" in the mosque which covers the site of the temple.

The second altar was the altar of incense, in the holy place of the tabernacle. It was of similar construction to the altar of burnt-offering, but smaller, being 2 cubits high and 1 cubit square (Exod. xxx. 1–5). It was overlaid with gold. Solomon's altar of incense (I. Ki. vi. 20) would appear to have been of cedar. But the authenticity of the passages describing the altar of incense in the tabernacle, and the historicity of the corresponding altar in Solomon's temple, are matters of keen dispute among critics. The incense altar in the second temple was removed by Antiochus Epiphanes (I. Macc. i. 21) and restored by Judas Maccabaeus (I. Macc. iv. 49). That in the temple of Herod is referred to in Luke i. 11.

On the first of these altars was a fire continually burning, in which the burnt-offerings were consumed. On the second an offering of incense was made twice a day. The use of the altar as an asylum is implied in Exod. xxi. 14. From I. Ki. i. 50, ii. 28, it would appear that the suppliant caught hold of the altar-horns (compare I. Ki. ii. 28).

Greece and Rome.—According to their respective uses, altars fell into two classes. Those of the first class were pedestals, so small and low that the suppliant could kneel upon them; these stood inside the temples, before the sacred image. The second class consisted of larger tables destined for burnt sacrifice; these were placed in the open air, and, if connected with a temple, in front of the entrance. The second class of altars, called *βωμοί* by the Greeks and *altaria* by the Romans, appears to have originated in temporary constructions such as heaps of earth, turf or stone, made for kindling a sacrificial fire as occasion required. But sacrifices to earth divinities were made on the earth itself, and those to the infernal deities in sunk hollows (*Odys.* x. 25; *Festus* s. v. *Altaria*). The note of Eustathius (*Odys.* xii. 252) seems to suggest survival of a primitive custom of offering sacrifice without an altar at all. Pausanias (vi. 20. 7) speaks of an altar at Olympia made of unbaked bricks. In some primitive holy shrines the bones and ashes of the victims sacrificed were allowed to accumulate, and upon this new fires were kindled. Altars so raised were considered as endowed with particular sanctity; notable instances are the altars of Hera at Samos, of Pan at Olympia, of Heracles at Thebes and of Zeus at Olympia (Paus. v. 14, 6; v. 15, 5; ix. 11, 7; v. 13, 5). The last-mentioned stood on a platform (*πρόθυσις*) measuring 125ft. in circumference, and led up to by steps, the altar itself being 22ft. high. Women were excluded from the platform. Where hecatombs were sacrificed, the *πρόθυσις* necessarily assumed colos-

sal proportions, as in the case of the altar at Parion, where it measured on each side 600ft. The altar of Apollo at Delos (*κεράτινος βωμός*) was made of the horns of goats believed to have been slain by Diana; at Miletus was an altar composed of the blood of victims sacrificed (Paus. v. 13, 6). The altar of Phorae in Achaea was of unhewn stones (Paus. vii. 22, 3); that used at the festival in honour of Daedalus on Mt. Cithaeron was of wood, and was consumed along with the sacrifice (Paus. ix. 3, 4). Others of bronze are mentioned. But these were exceptional. The usual material of an altar was marble, and its form, both among the Greeks and Romans, was either square or round; polygonal altars, of which examples still exist, being exceptions. When sculptured decorations were added they frequently took the form of festoons like those used to ornament altars, or of symbols, such as crania and horns of oxen, referring to the victims sacrificed. Altars apart from temples usually bore the name of the person by whom they were dedicated, and the name, or a representation, of the deity in whose service they were. An altar was usually retained for the service of one particular god, but joint dedications occur, as in the case of the altar at Olympia to Artemis and Alpheus jointly, or that of Poseidon and Erechtheus in the Erechtheum at Athens; at Oropus the altar was divided into five parts, one dedicated to Heracles, Zeus and Paean Apollo, a second to heroes and their wives, a third to Hestia, Hermes, Amphiarus and the children of Amphilocheus, a fourth to Aphrodite Panacea, Jason, Health and Healing Athene, and the fifth to the Nymphs, Pan and the rivers Archelous and Cephissus (Paus. i. 34. 2). Deities of an inferior order, who were conceived as working together—e.g., the wind gods—had an altar in common. In the same way, the "unknown gods" were regarded as a unit, and had in Athens and at Olympia one altar for all (Paus. i. 1, 4; v. 14, 5; cf. Acts xvii. 23). An altar to all the gods is mentioned by Aeschylus (*Supp.* 222). Other exceptional classes of altars are those on which fire could not be kindled (*βωμοί ἀπυροί*), and those which were kept free from blood (*βωμοί ἀνάλμακτοι*), of which in both respects the altar of Zeus Hypatos at Athens was an example. The *ἑστία* was a round altar; the *ἑσχάρα*, one employed apparently for sacrifice to inferior deities or heroes (but *ἑσχάρα Φοιβου*, Aesch. *Pers.* 205). In Rome an altar erected in front of a statue of a god was always required to be lower than the statue itself (Vitruvius iv. 9). Altars were always places of refuge, and even criminals and slaves were there safe, violence offered to them being insults to the gods whose suppliants the refugees were for the time being.

Ancient America.—As a single specimen of an altar, wholly unrelated to any of the foregoing, we may cite the ancient Mexican example described by W. Bullock (*Six Months in Mexico*, London, 1824, p. 335). This was cylindrical, 25ft. in circumference, with sculpture representing the conquests of the national warriors in 15 different groups round the side.

Portable altars and tables of offerings were used in pre-Christian as well as in Christian ritual. One such was discovered in the Gezer excavations, dating about 200 B.C. It was a slab of polished limestone about 6in. square with five cups in its upper surface. Another from the same place was a small cubical block of limestone bearing a dedication to Heracles. They have also been found in Assyria. Pocket altars are still used in some forms of worship in India. See the *Journal of the Royal Asiatic Society*, 1852, p. 71.

ALTARS IN THE CHRISTIAN CHURCH

I. The Early Church.—The altar is spoken of by the early Greek and Latin ecclesiastical writers under a variety of names:—*τράπεζα*, the principal name in the Greek fathers and the liturgies; *θυσιαστήριον* (rarer; used in the Septuagint for Hebrew altars); *λαστήριον*; *βωμός* (usually avoided, because of its pagan associations); *mensa Domini*; *ara* (avoided like *βωμός* for the same reason); and, most regularly, *altare*.

In his reply to Celsus (p. 389), who has charged the Christians with being a secret society, "because they forbid to build temples, to raise altars," Origen says, "The altars are the heart of every Christian." We gather from this, and from a passage in Lactantius, *De Origine Erroris*, ii. 2, that down to about A.D. 250, or perhaps

a little later, the communion was administered on a movable wooden table. In the Catacombs, the *arcosolia* or bench-like tombs are said (though the statement is doubtful) to have been used for this purpose. The earliest church altars were certainly made of wood; and it appears from a passage in William of Malmesbury (*Gesta Pontif.* iii. 14) that in the diocese of Worcester altars were of wood down to the middle of the 11th century.

II. **The Mediaeval Church.**—It will be convenient now to pass to the fully-developed altar of the Western Church with its accessories.

In the Roman Catholic Church the component parts of a fixed altar are the table (*mensa*), consisting of a stone slab; the support (*stipes*), either a solid mass or four or more columns; the *sepulchrum*, or altar-cavity, a small chamber for the reception of relics. If the support consist of columns, the intervals may be filled with other materials, *e.g.*, brick or cement. The table alone is consecrated, and in sign of this are cut in its upper surface five Greek crosses, one in the centre and one in each corner. These crosses must have been anointed by the bishop with chrism in the ritual of consecration before the altar can be used. Crosses appear on the portable altar buried with St. Cuthbert (A.D. 687), but the history of the origin and development of this practice is not fully worked out.

According to the *Caeremoniale* (i. 12, 13) a canopy (*baldachinum*) should be suspended over the altar; this should be square and large enough to cover the altar and the *predella* on which the celebrant stands. It is sometimes hung from the roof by chains so that it can be lowered or raised; sometimes it is fixed to the wall or reredos; sometimes it is a solid structure of wood covered with metal or of marble supported on four columns. This last form is, however, usual only in large churches, more especially of the basilica type, *e.g.*, St. Peter's at Rome or the Roman Catholic cathedral at Westminster. The origin of the canopy (called liturgically the *ciborium*) is uncertain, but it appears in a mosaic at Thessalonica of a date not later than A.D. 500. The Congregation of Rites (May 27, 1697) ordered it to be placed over all altars, but even at Rome it is usually only found over the high altar and the altar of the Blessed Sacrament.

Multiplication of altars is a mediaeval characteristic, no trace of which appears before the 4th century. In the church of St. Gall, Switzerland, in the 9th century there were 17. In the modern Latin Church almost every large church contains several altars. Archbishop Wulfred in 816 ordered that beside every altar there should be an inscription recording its dedication. This regulation fell into abeyance after the 12th century, and such inscriptions are very rare. One remains mutilated at Deerhurst (*Archaeologia*, vol. 50, p. 69).

The principal altar, in a church having more than one, is called a "high altar." Where there is a second high altar, it is generally at the end of the choir or chancel. In monastic churches (*e.g.*, formerly at St. Albans) it sometimes stands at the end of the nave close to the choir screen.

Beside the altar was a drain (*piscina*) for pouring away the water in which the communion vessels were rinsed. This seems originally to have been under the altar, as it is still in the Eastern Church.

In the time of Optatus (*c.* A.D. 370), bishop of Milevis, and probably earlier, the altar was covered with a cloth. This had developed by the 14th or 15th century into a cerecloth, or waxed cloth, on the table itself; and three linen coverings one above the other, two of about the size of the table and one rather wider than the altar, and long enough to hang down at each end. In front was often a hanging panel of embroidered cloth (the frontal); but frontals of wood, ornamented with carving or enamel, etc., are also to be found. These embroidered frontals are changeable, so that the principal colour in the pattern can accord with the liturgical colour of the day. A similar panel of needlework (the dossal) is suspended behind the altar.

Portable altars have been used on occasion since the time of Bede. They are small slabs of hard stone, just large enough for the chalice and paten. They are consecrated and marked with the five incised crosses in the same way as the fixed altar, but they

may be placed upon a support of any suitable material, whether wood or stone.

III. **Post-Reformation Altars.**—At the Reformation the altars in churches were looked upon as symbols of the unreformed doctrine. In England the name "altar" was retained in the English Communion Office printed in 1549, and in the First Prayer Book of Edward VI. But the altars were soon after ordered to be destroyed, and replaced by movable wooden tables; while in the revised Prayer Book of 1552 the term "God's board" or "the table" was substituted for "altar." After a temporary reaction under Mary, the work of reformation was resumed under Elizabeth.

The name "altar" has been retained in the English Coronation Office. In the canons of 1640 it was recognized, but with the reservation that "it was an altar in the sense in which the primitive church called it an altar and in no other"; and the rule for the position of the communion tables, which has been since regularly followed throughout the Church of England, was formulated. In the primitive church the altars seem to have been so placed that, like those of the Hebrews, they could be surrounded on all sides by the worshippers. The chair of the bishop or celebrant was on their east side, and the assistant clergy were ranged on each side of him. But in the middle ages the altars were placed against the east wall of the churches, or against a *reredos* erected at the east side of the altar; the celebrant was thus brought round to the west side and caused to stand between the people and the altar. When tables were substituted for altars in the English churches, these were not merely movable, but at the administration of the Lord's Supper were actually moved into the body of the church, and placed *table-wise*—that is, with the long sides turned to the north and south, and the narrow ends to the east and west—the officiating clergyman standing at the north side. In the time of Archbishop Laud, however, the present practice of the Church of England was introduced. The communion table, though still of wood and movable, is, as a matter of fact, never moved; it is placed *altar-wise*—that is, with its longer axis running north and south, and close against the east wall. Often there is a *reredos* behind it; it is also fenced in by rails to preserve it from profanation of various kinds.

In 1841 a stone altar, consisting of a flat slab resting on three upright slabs, was set up by the Camden society in the ancient church of the Holy Sepulchre at Cambridge, at the east wall of the chancel. But the Court of Arches in 1845 ordered it to be removed, on the ground that a weighty stone structure was not a communion-table in the sense recognized by the Church of England.

BIBLIOGRAPHY.—For altars in the ancient East see M. Jastrow, *Religion of Assyria and Babylonia*; Perrot and Chipiez, *Art in Chaldaea* (i. 143, 255); Sir J. Gardiner Wilkinson, *A Second Series of the Manners and Customs of the Ancient Egyptians*, ii. 387; Benzinger's and Nowack's works on *Hebräische Archäologie*. For classical altars, much information can be obtained from the notes in J. G. Frazer's *Pausanias*. See also Schömann, *Griechische Alterthümer*, vol. ii.; the volume on "Gottesdienstliche Alterthümer" in Hermann's *Lehrbuch der griechischen Antiquitäten*. On domestic altars and worship see Petersen, *Hausgottesdienst der Griechen* (Cassel, 1851). On plural dedications consult Maurer, *De aribus graecorum pluribus deis in commune positis* (Darmstadt, 1885). For Christian altars, reference is best made to the articles on the subject in the dictionaries of Christian and liturgical antiquities of Cabrol, Migne, Martigny, Smith and Cheetham, and Pugin, where all the available information is collected. See also Ciampinus, *Vetera Monumenta* (Rome, 1747), where numerous illustrations of altars are to be found; Martene, *De antiquis Ecclesiae ritibus*, iii. vi. (Rouen, 1700); Voigt, *Thysiaserologia sive de altaribus veterum Christianorum* (Hamburg, 1709); and the liturgical works of Bona. Many articles on various sections of the subject have appeared in the journals of archaeological societies; we may mention Nesbitt on the churches of Rome earlier than 1150 (*Archaeologia*, xl. p. 210), Didron, "L'Autel chrétien" (*Annales archéologiques*, iv. p. 238), and a paper by Texier on enamelled altars in the same volume.

ALTAZIMUTH, an astronomical telescope of a pattern similar to a theodolite but on a much larger scale. It is used principally to observe positions of the moon before first quarter and after last quarter, when the moon passes across the meridian in daylight. In order to secure more favourable nocturnal observations at such times it is necessary to have an instrument which can be turned out of the meridian but in other respects is used similarly to a meridian circle.

ALTDAMM, a town on the Oder, opposite Stettin, in the district of Stettin, in the Prussian province of Pomerania. Pop. (1925) 8,678. Its manufactures (starch, cellulose and syrup) are mainly based on potato cultivation.

ALTDORF, capital of the Swiss canton of Uri, 1,516ft. above sea-level, a little above the right bank of the Reuss, not far above the point where this river is joined on the right by the Schächen torrent, 34m. from Lucerne by the St. Gotthard railway and 22m. from Göschenen. Pop. (1920), 4,163, Roman Catholic and German speaking. Its port on the Lake of Lucerne, Flüelen, is 2m. distant. There is a stately parish church, while above the little town is the oldest Capuchin convent in Switzerland (1581). William Tell shot the apple from his son's head, according to tradition, in the market-place, where in 1895, at the foot of an old tower (with rough frescoes commemorating the feat), there was set up a fine bronze statue (by Richard Kissling of Zürich) of Tell and his son. In 1899 a theatre was opened for the performance of Schiller's play of *Wilhelm Tell*. The same year a new carriage-road was opened from Altdorf through the Schächen valley and over the Klausen Pass (6,404ft.) to the village of Linththal (30m.) and so to Glarus. Near Altdorf is the village of Bürglen, where by tradition Tell was born; while he is also said to have lost his life, while saving that of a child, in the Schächen torrent. On the left bank of the Reuss, opposite Altdorf is Attinghausen, where the ruined castle now houses the cantonal museum.

ALTDORFER, ALBRECHT (?1480-1538), German painter and engraver, was born at Regensburg (Ratisbon), where in 1505 he was enrolled a burgher, and described as "twenty-five years old." Soon afterwards he is known to have been prosperous, and as city architect he erected fortifications and a public slaughter-house. Altdorfer has been called the "Giorgione of the North." His paintings are remarkable for minute and careful finish, and for close study of nature. The most important of them are to be found in the Pinakothek at Munich. A representation of the battle of Arbelá (1529), included in that collection, is usually considered his chief work. His engravings on wood and copper are very numerous. The most important collection is at the Berlin museum. Albrecht's brother, Erhard Altdorfer, was also a painter and engraver, and a pupil of Lucas Cranach.

ALTEN, SIR CHARLES (KARL) (1764-1840), Hanoverian and British soldier, son of the Hanoverian Baron Alten, took service in the King's German Legion in British pay, and commanded the light infantry in the Hanoverian expedition of 1805, at the siege of Copenhagen in 1807, with Moore in Sweden and Spain, and in the Walcheren expedition. He commanded a brigade at Albuera, and in 1813 the famous "Light Brigade" in Spain. In 1815 he was in command of the 3rd Division, and was wounded at Waterloo. His conduct won for him the rank of Count von Alten. He returned in 1818 to Hanover, where he rose to the rank of field-marshal. Count von Alten, however, remained in the British Army as Major-Gen. Sir Charles Alten.

See *Gentleman's Magazine* (1840); N. L. Beamish, *Hist. of the King's German Legion* (1832-37).

ALTENA, a town in Westphalia, Germany, 30m. S.S.E. of Dortmund. Pop. (1925) 16,192. It lies in the deep valley of the Lenne, and forms a single street 3m. in length. The Schlossberg is the ancestral castle of the counts of La Marck. Metal industries and especially wire making are carried on.

ALTENBURG, a town in Thuringia, Germany, formerly capital of the duchy of Saxe-Altenburg, 23m. south of Leipzig. Pop. (1925) 42,109. From its ancient castle, on a lofty porphyry rock, Kunz von Kaufungen carried off, in 1455, the young princes Albert and Ernest, founders of the royal and ducal families of Saxony. Altenburg has local courts subordinate to those of Jena and a cathedral and various learned societies. There is also a museum, with natural history, archaeological and art collections, and among other buildings St. Bartholomew's church (1089) and the town hall (1562-64). There is considerable traffic in grain, horses and cattle of the surrounding districts. There are lignite mines in the vicinity. The town has foundries and machinery works. Hats, gloves, shoes, metal objects, brushes, musical in-

struments, paper and paper bags, cigars, playing cards and chemicals are made. The card-game of "Skat," universal in Germany since 1835, originated among the peasantry here.

ALTENSTEIN, a castle in Saxe-Meiningen, Germany, on the S.W. slope of the Thüringerwald not far from Eisenach. It has associations with Boniface (c. 724) and with Martin Luther.

ALTERATIVE, an old term in the *materia medica* which comprised a group of substances which had, or were supposed to have, a specific influence on the nutritional processes of the body. They were mainly of the metal or metalloid class and included such things as iron, mercury, phosphorus, manganese and arsenic. Their mode of action was to "change" the metabolism of the organism as a whole or in any of its parts. Thus arsenic acts on the skin, causing changes in its rate of growth and nutrition. Iron exerts a profound influence on the blood. This rather vague group has fallen into disrepute and is not even mentioned in several of the more recent books on *materia medica*. The reason for this is that further research has brought to light the biochemical reactions underlying the "alterations," and some of these excellent remedies have been removed to more scientific groups.

ALTERNATING CURRENT, electric current which grows to a maximum value, decreases, changes its direction (with respect to a datum line), reaches a maximum value in the new direction (which is equivalent to a minimum value for the original direction), and returns to its original value, whence it repeats this cycle an indefinite number of times. The interval which elapses between the attainment of a definite value on two successive occasions is called the *period*, and the number of cycles or periods per second, the *frequency* of the alternating current, high frequency currents having several thousand cycles per second. The *amplitude* is the deviation of the maximum (or of the minimum) from the datum line. (See *ELECTRICITY*.)

ALTERNATION, process of "alternating," i.e., of two things following one another regularly by turns, as night and day. In American political representative bodies and in the case of company directors, a substitute is sometimes called an "alternate." An "alternative" is that which is offered as a choice of two things, the acceptance of the one implying the rejection of the other.

ALTERNATOR, a dynamo generating alternating current. (See *ELECTRIC GENERATOR*; *MOTOR*, *ELECTRIC*.)

ALTGELD, JOHN PETER (1847-1902), American politician, was born in Nieder Selters, Prussia, Germany, on Dec. 30, 1847. In infancy he was brought to the United States by his parents who settled near Mansfield, Ohio. In 1864 he entered the Union army and served for one hundred days as a private. For a time he was a school teacher, subsequently he studied law, and in 1869 he was admitted to the bar. From 1886 to 1891 he was a judge of the superior court in Chicago and from 1893 to 1897 he was governor of Illinois. His pardon, while governor, of the Chicago anarchists, imprisoned for participation in the Haymarket riot (q.v.), caused extensive comment. He was a convincing public speaker and effectively promoted the cause of prison reform. Espousing the financial doctrine of free silver, he became one of its leading advocates, and, in the presidential campaigns of 1896 and 1900, vigorously supported the candidacy of William Jennings Bryan. He published *Our Penal Machinery and Its Victims* (1890) and *Live Questions* (1890). He died in Joliet, Ill., on March 12, 1902.

See W. R. Browne, *Altgeld of Illinois* (1924); Edgar Lee Masters, "John Peter Altgeld" in *American Mercury*, vol. iv., pp. 161-174 (1925).

ALTHAEA, in Greek and Roman mythology, daughter of Thestius, king of Aetolia, wife of Oeneus, and mother of Meleager (q.v.).

ALTHIBUROS (mod. MEDEINA), an ancient city of Numidia on the road between Carthage and Theveste (Tebessa), which was constructed by Hadrian in 123 A.D., 22m. S. of Kef. The town, originally an indigenous settlement, obtained municipal rights from Hadrian, like several other cities of North Africa. It enjoyed considerable prosperity in the 2nd and 3rd centuries after Christ, and was the seat of a bishop from the 5th

to the beginning of the 8th century. There is a well-preserved triumphal arch on the site, and excavations have brought to light the ancient forum and the buildings surrounding it, including two temples, a fallen arch erected in honour of Hadrian, the theatre and some houses with fine mosaic pavements.

See A. Merlin, *Forum et Maisons d'Althiburos* (1913).

ALTHING, the legislative assembly of Iceland (*q.v.*).

ALTICHERO DA ZEVIO (c. 1320–c. 1385), Italian painter, of the Veronese school, born at Zevio, a village near Verona. His standard work is the fresco decoration of the San Felice chapel in the church of Sant' Antonio at Padua, representing the "Crucifixion" and "Scenes from the Legend of St. James," painted about 1380. The frescoes in the adjacent capella San Giorgio are not on the same high level and were probably mainly executed by his pupil Jacopo d'Aranzo. The only extant works of Altichiero in Verona are the fresco in the church of Sant' Anastasia representing the "Knights of the Cavalli family kneeling before the Virgin," and another, representing the Crucifixion, in the church of San Zeno. Altichiero was the head of the Veronese School of the Trecento, whose art represented the ideal of a chivalrous aristocracy and embodied the romantic and heroic aspect of the middle ages. In his paintings the pictorial point of view predominates. They are essentially the work of a colourist. Architecture and figures are conceived together; scenes are enacted in roomy interiors. There is, moreover, a certain tendency to depict incidentals, which contrasts with Giotto's concentrated and expressive style, where the figures stand out plastically and everything is subordinated to the main theme. Altichiero's style was not influenced by Giotto.

ALTIMETER. In aerial navigation, an instrument employed to determine the height of aircraft above the ground or, more accurately, above sea level. It is a form of aneroid barometer, for it is based upon the changes of air pressure which are registered as an aeroplane ascends or descends. All altimeters are set at zero when the aircraft leaves the ground and they are calibrated in accordance with a standard atmosphere which has been adopted internationally. The standard atmosphere assumes that, at sea level, the temperature is 15° C and that the barometric height reduced to 0° C is 760mm. of mercury. The decrease of temperature with increase of height is assumed to be 6.5° C per kilometer. Altimeters so calibrated are usually accurate to within 2% to 3%. For some purposes however a greater accuracy is necessary; this can be achieved by applying a correction obtained from a knowledge of the temperature on the ground and at the operating height. Carefully designed altimeters, so corrected, are capable of an accuracy of the order of 1% so long as the conditions of atmospheric temperature and pressure do not vary. An altimeter can not distinguish a change of height from a general fall of atmospheric pressure caused by an approaching depression.

In principle the solution is clear, the height above the ground or sea must be measured directly and not inferred from a knowledge of the atmospheric conditions at the operating height. No instrument for this purpose however is yet in general use. Perhaps the nearest approach to success has been achieved by the Behm height-finding apparatus developed in Germany, and tested during the flight to America of the airship ZR3. In this instrument a very sensitive timing mechanism is started automatically at the instant at which a sound is emitted from the airship. The sound wave travels to the ground and is reflected back to the airship, and the timing mechanism is automatically stopped when the reflected sound wave reaches the airship. The weight of the apparatus—an all important factor when considering the design of aircraft instruments—compares unfavourably with the almost negligible weight of an altimeter.

ALTINUM (mod. *Altino*), Venetia, 12m. S.E. of Tarvisium (Treviso), on the lagoons. From a fishing village it became the junction of the Via Postumia and the Via Popilia (see *AQUILEIA*). Augustus and his successors made it important as a point on the route between Italy and the north-east parts of the empire. After the foundation of the naval station at Ravenna, it became the practice to take ship from there to Altinum, and thence to continue the journey by land. A new road, the Via Claudia Augusta,

was constructed by the emperor Claudius from Altinum to the Danube, a distance of 350m.

ALTITUDE, height or eminence, and particularly the height above the ground or above sea-level. In geometry, the altitude of a triangle is the length of the perpendicular from the vertex to the base. In astronomy, the altitude of a heavenly body is the apparent angular elevation of the body above the plane of the horizon (see *ASTRONOMY: Spherical*). *Apparent altitude* is the value which is directly observed; *true altitude* is deduced by correcting for astronomical refraction and dip of the horizon; *geocentric altitude* by correcting for parallax.

ALTMAN, BENJAMIN (1840–1913), American merchant and art collector, was born in New York, N.Y., July 12, 1840, where he was educated and achieved his business career. In 1905 he erected a large store on Fifth avenue which, with the additions on Madison avenue built in 1913–14, made his establishment one of the great department stores of the world. Besides his outstanding success as a merchant he won wide reputation as an art collector. He formed a large and exceedingly valuable collection of paintings, especially of the old masters, among them 13 Rembrandts and some fine pictures by Botticelli, Filippo Lippi and Holbein. He purchased in 1912 the Velasquez portraits of King Philip IV. of Spain and of Olivares, for which he was reported to have paid about \$1,000,000. He also made extensive collections of Chinese porcelains, rugs, crystals and other objects of art. The major part of his art collections was bequeathed to the Metropolitan Museum of Art, New York city, and constitutes one of the most important gifts received by that institution. He died in New York city, Oct. 8, 1913.

ALTMÜHL, a river in Bavaria, Germany, an important left bank tributary of the Danube, rising in the Franconian plateau, and after a tortuous course of 116m. alternatively through meadows and in romantic gorges, joining the Danube at Kelheim. It is navigable up to Dietfurt (18m.), whence the Ludwigscanal (100m. long) leads to Bamberg on the Regnitz, thus establishing communication between Danube and Rhine.

ALTO, a musical term applied to the highest adult male voice or counter-tenor, and to the lower kind of boy's or woman's (contralto) voice. It is typical of the confusing character of musical nomenclature that the term which originally meant "high" should have come to signify the lower of its particular class of voice. It is further applied to the viola as representing the alto voice of the violin family.

ALTON, urban district, Hampshire, England, 46½m. S.W. of London by the S.R. Population (1931) 6,172. It occupies a pleasant, undulating site near the headwaters of the river Wey. Of the church of St. Lawrence, part, including the tower, is Norman; the building was the scene of a fierce conflict between the royalist and parliamentary troops in 1643. There is a museum of natural history; the collection is reminiscent of the famous naturalist, Gilbert White, of Selborne in this vicinity. Large markets and fairs are held for corn, hops, cattle and sheep; and the town contains some breweries and iron foundries.

ALTON, a city of Madison county, Ill., U.S.A., on the Mississippi river, about 5m. above the mouth of the Missouri and 25m. N. of St. Louis. It is on the Mississippi valley highway; is served by the Chicago and Alton, the Big Four, and the Alton and Eastern railways, and for freight also by the Burlington and the Missouri-Kansas-Texas; and has connections for freight through the Illinois Terminal railroad with all the railways entering East St. Louis. The business streets are on the bottom lands, but the residential part of the city lies on picturesque bluffs which rise to a height of 250 feet. The population in 1920 was 24,682, of whom 1,707 were negroes and 1,670 were foreign-born whites; and was estimated 30,151 in 1930.

Transportation facilities, cheap coal, unlimited water, abundant building material, and hydro-electric power have favoured industrial development. The value of the products manufactured in 1927 was \$19,609,062, and there are also important establishments near by in the surrounding country, including several large oil refineries, to which crude petroleum is brought by pipe lines from Texas and Oklahoma. The leading manufactures are glass bottles,

brick, ammunition, flour, petroleum products, lime and stone, pig lead, iron and steel, box board and paper. Shurtleff college (Baptist, founded in 1827), at Upper Alton, 1½ m. N.E. of Alton, and Monticello seminary for girls, at the village of Godfrey, 5½ m. N. (founded 1835), were among the earliest educational institutions in the Mississippi valley.

The first white settler here was Jean Baptiste Cardinal, who built a loose rock shelter in 1783, but was soon taken prisoner by the Indians. Just south of Alton, Lewis and Clark camped through the winter of 1803-04. The town was planned in 1815 by Col. Rufus Easton of St. Louis, who gave it the name of one of his sons. In 1833 it was organized as a town, and in 1837, when the population was about 4,000, it was incorporated as a city. The first State institution in Illinois, a penitentiary, was located here in 1827. Later the prisoners were transferred to Joliet, and during the Civil War the buildings were used as a military hospital and prison. Intense excitement was caused throughout the country in 1837 by the persecution and finally (on Nov. 7) the killing, by a pro-slavery mob, of Elijah P. Lovejoy (b. 1802), the editor of an abolitionist journal. In 1897 on the 60th anniversary of his death a monument, erected by the State and the citizens of Alton, was dedicated to his memory.

ALTONA, a town in Schleswig-Holstein, Germany, on the right bank of the Elbe. Though closely adjoining Hamburg on the west, Altona is administered separately. Pop. (1880) 91,049; (1900) 161,508; (1925) 185,135. The name may be derived from *allzu-nah* ("all too near"), the Hamburgers' designation for an inn which in the 16th century lay too close to their territory. For a long time this was the only house in the locality. When Altona passed to Denmark (1640) it was a small fishing village, but the Danish kings granted it customs privileges and exemptions to make it a formidable rival to Hamburg. Although burnt by the Swedes in 1713, it rapidly recovered and, despite the Napoleonic wars, increased in prosperity. After 1853, when Denmark withdrew the privileges, its trade waned. Occupied in 1864 in the name of the German Confederation it passed to Prussia after the war of 1866, and in 1888, together with Hamburg, joined the Zollverein, while retaining certain free trade rights over the *Freihafengebiet* which it shares with Hamburg and Wandsbek. Lying higher than Hamburg, Altona enjoys a purer and healthier atmosphere. The Palmaille, one of the numerous wide streets, ends in a terrace about 100 ft. above the Elbe. An elevated railway connects the town with Hamburg and provides through communication with the main Prussian railway systems. Altona manufactures tobacco and cigars, machinery, woollens, cottons, chemicals, leather, soap and oil. The port carries on an extensive trade with Great Britain, France and America, but most of its business is transacted on the Hamburg exchange; while the magnificent warehouses at Altona are largely used by Hamburg merchants. Since 1888 much has been spent at various times, especially in 1918, upon improvement and enlargement of the harbour. The exports and imports resemble those of Hamburg. In 1925 the net tonnage of boats entering was 557,196. Some fishing is carried on and there are ship-repairing yards. In 1890 the populous suburbs of Ottensen to the west, Bahrenfeld, Othmarschen and Övelgönne were incorporated with the town.

ALTOONA, city of Blair county, Pa., U.S.A., on the Pennsylvania railroad, 114 m. E. by N. of Pittsburgh. It lies in the upper end of Logan valley, 1,180 ft. above sea-level, in the "central Pennsylvania" bituminous coal-field, and commands views of some of the most picturesque mountain scenery in the State. The famous Horseshoe curve is 4 m. to the west. The population was 60,331 in 1920, of whom 5,312 were foreign-born whites, and was 82,054 in 1930.

Altoona was created by the Pennsylvania Railroad Company, which in 1849 bought farm lands here and laid out a town, to be the base of operations while it was constructing the pioneer railway across the Alleghenies. The Pennsylvania Railroad Company is still the chief factor in the city's economic life. Its repair shops, foundries and works for the construction of cars and locomotives employ several thousand men. The output of the city's factories in 1927 was valued at \$47,875,940. The assessed valuation of

property in 1927 was \$67,980,735. Altoona was incorporated as a borough in 1858 and chartered as a city in 1868. In 1862 the "loyal war governors" of the northern States met here, in the Logan house, to renew their pledge of support to Lincoln.

ALTO-RILIEVO (Ital. for "high relief"), the term applied to sculpture that projects from the plane to which it is attached

to the extent of more than one-half the outline of the principal figures, which may be nearly, or in parts, entirely detached from the background, thus distinguishing it from *basso-rilievo* (*q.v.*). It is not only the actual degree of relief, high or low, which is implied by these two terms, but a resultant difference also of design and treatment necessitated by the contingent differences of light and shadow. (*See SCULPTURE: Technique, Modelling.*)

AFTER AN ALTO-RELIEVO OF MERCURY, EURYDICE AND ORPHEUS IN THE MUSEO NAZIONALE, NAPLES

ALTRANSTÄDT, a village of Germany, in Prussian Saxony near Merseburg. Altranstädt is famous in history for two treaties concluded here: (1) the peace which Augustus II., king of Poland and elector of Saxony, was forced to ratify (Sept. 24, 1706) with Charles XII. of Sweden, whereby the former renounced the throne of Poland in favour of Stanislaus Leszczynski—a treaty which Augustus declared null and void after Charles XII.'s defeat at Poltava (July 8, 1709); (2) the treaty of Aug. 31, 1707, by which the emperor Joseph I. guaranteed to Charles XII. religious tolerance and liberty of conscience for the Silesian protestants.

ALTRINCHAM or **ALTRINGHAM**, urban district, Cheshire, England, 8 m. from Manchester, on the L.M.S. and Cheshire Lines Railways. Population (1911) 17,813, (1931) 21,356. The town of Altrincham (Altringham) was originally included in the barony of Dunham Massey. Hamon de Massey granted a charter to his burgesses, establishing the Court Leet, on receiving a concession of a market and an annual fair from Edward I. in 1290. Edward II. substituted a fair held on the eve, feast and morrow of St. James's day yearly. This fair continued to be held until recently under the name of "Sanjam" fair. It is believed to have been the practice since the charter was granted for the Court Leet to elect a mayor annually; and this is still done by a jury of the Leet of the borough, which consists of burgesses only. The Court Leet was formerly all-powerful in regulating the affairs of the town; and various officials were appointed (*e.g.*, constables, bailiffs, market lookers, scavengers, swine lookers and bellman) by the court to assist the mayor. All these officers performed their duties until the formation of a local board of health; and they are still elected at the autumnal meeting of the Leet, though their duties are purely nominal. Altrincham is now governed by an Urban District Council. Market gardening is carried on, fruit and flowers being grown for sale in Manchester. During the last 25 years, owing to good rail and canal facilities, a large number of works, mostly of an engineering nature, have been built on the north side of Altrincham. The old trades of cotton and worsted are no longer carried on, and although there is still some cabinet-making it is not so important as formerly.

ALTRUISM, a philosophical term used in ethics for that theory of conduct which regards the good of others as the end of moral action. It was invented by Auguste Comte and adopted by the English positivists as a convenient antithesis to egoism. According to Comte the only practical method of social regeneration is gradually to inculcate the true social feeling which subordinates

itself to the welfare of others. The application to sociological problems of the physical theory of organic evolution further developed the altruistic theory. According to Herbert Spencer, the life of the individual in the perfect society is identical with that of the state: in other words, the first object of him who would live well must be to take his part in promoting the well-being of his fellows individually and collectively. Pure egoism and pure altruism are alike impracticable. For on the one hand unless the egoist's happiness is compatible to some extent with that of his fellows, their opposition will almost inevitably vitiate his perfect enjoyment; on the other hand, the altruist whose primary object is the good of others, must derive his own highest happiness—i.e., must realize himself most completely—in the fulfilment of this object. In fact, the altruistic idea, in itself and apart from a further definition of the good, is rather a method than an end.

The self-love theory of Hobbes, with its subtle perversions of the motives of ordinary humanity, led to a reaction which culminated in the utilitarianism of Bentham and the two Mills; but their theory, though superior to the extravagant egoism of Hobbes, had this main defect, according to Herbert Spencer, that it conceived the world as an aggregate of units, and was so far individualistic. Sir Leslie Stephen in his *Science of Ethics* insisted that the social organism is the unit, and therefore that the aim of moralists is not the "greatest happiness of the greatest number," but rather the "health of the organism." The socialistic tendencies of subsequent thinkers have emphasized the ethical importance of altruistic action, but it must be remembered always that it is ultimately only a form of action, that it may be commended in all types of ethical theory, and that it is a practical guide only when it is applied in accordance with a definite theory of "the good." Finally, he who devotes himself on principle to furthering the good of others as his highest moral obligation is from the highest point of view realizing, not sacrificing, himself.

See works of Comte, Spencer, Stephen, and text-books of ethics (cf. bibliography at end of article ETHICS).

ALTUS, a city of south-western Oklahoma, U.S.A., 15m. from the Red river; the county seat of Jackson county. It is served by the Frisco, the Kansas City, Mexico and Orient and the Missouri-Kansas-Texas railways. The population in 1920 was 4,522 (95% native white), and in 1930, after annexations of territory, was 8,439 by the United States census. It is a shipping point for alfalfa, cotton and grain, and has 35 industrial plants and 25 wholesale houses. The city was founded in 1891 and incorporated in 1909.

ALTWASSER, a town in Lower Silesia, Germany, now incorporated in Waldenburg-in-Schlesien.

ALTYN TAGH, the northernmost of the constituent ranges of the Kuenlun (*q.v.*), which separates the high plateau of Tibet on the south from the depression of the Tarim basin on the north (see ASIA).

ALUDEL, a pear-shaped pot, generally made of earthenware and open at both ends, so that a series may be formed, the neck of one aludel fitting into the base of the next. Aludels were used by the early chemists and are still employed at Almaden in Spain, in connection with the extraction of mercury (*q.v.*) from its ores.

ALUM, the name given in commerce and by long popular usage to a double salt composed of aluminium sulphate and potassium sulphate. In chemistry the name is applied to a whole series of sulphates, which form one of the most important examples of isomorphism (*q.v.*). The potassium of common alum may be replaced by ammonium, sodium, potassium, rubidium, silver, caesium, and thallium (and possibly lithium). Further, the aluminium itself, from which the substance derives its name, may also be replaced by other trivalent metals, titanium, vanadium, chromium, manganese, iron, cobalt, gallium, rhodium, indium and iridium, so that there are many possible alums containing neither aluminium or potassium. Also selenium may replace sulphur in the acid radical in some of the alums as, e.g., in aluminium ammonium selenate, $\text{Al}_2(\text{SeO}_4)_3 \cdot (\text{NH}_4)_2\text{SeO}_4 \cdot 24\text{H}_2\text{O}$, or in the sulphate-selenate, $\text{Al}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SeO}_4 \cdot 24\text{H}_2\text{O}$. An aluminium hydroxylamine alum, and alkyl-ammonium alum, may also be prepared. Thus the term covers the double sulphates or selenates of a univalent and a

trivalent element or radicle, crystallizing in octahedra or cubes with 24 molecules of water of crystallization. Of the theoretically possible alum combinations a relatively small number only have been isolated; thus some 47 sulphate alums have been reported.

The alums crystallize in the regular system in octahedra with 24 molecules of water; from a basic solution of ordinary alum the cube tends to predominate. In a practically cold solution of the latter character an octahedron may gradually be grown into the cube, the composition of the crystal remaining unaltered. Owing to the symmetry of the crystal form, perfect single octahedra of large size may be obtained by slow crystallization in the cold. An octahedron weighing $1\frac{1}{4}$ cwts. has been grown in this way in a period of about two years. On the detailed structure of the alums as deduced from X-ray examination, see J. M. Cook (*Phil. Mag.*, 1927, 4, p. 688).

The aluminium sulphate alums have an astringent and acid yet sweetish taste. Potassium and ammonium alum crystals are permanent in the air; the sodium salt tends somewhat to effloresce. The alums melt in their crystal water between about 37°C . for ferric thallium alum, and 117°C . for aluminium caesium alum. By careful heating, especially in a current of warm air, ordinary alum may ultimately be completely dehydrated at 100°C . If heated rapidly it intumesces and forms a very light bulky porous mass of "burnt alum." From the ammonium alum further heating at high temperature leaves the pure sesquioxide of aluminium.

The solubilities of the alums vary widely: the quantity dissolved by 100 parts of cold water (15°C .) may be illustrated by the following figures for some of the aluminium alums—caesium alum 0.35 part, potassium alum 9.59 parts, ammonium alum 12.66 parts, sodium alum 51 parts (16°C .). Water will dissolve several times its own weight of potassium alum at 90°C . The aqueous solutions act as weak acids. Aluminium alums find employment in a wide range of industries among which are dyeing, paper-making, tanning, water purification, pigment lakes, and plaster: chromium alum is used in dyeing and tanning.

Preparation.—The very early history of the manufacture of alum is unknown. Potash alum, aluminium sulphate, and ferrous and ferric sulphates all occur native as efflorescent salts or earthy impregnations in varying degree of admixture and purity, and the *alumen* of Pliny (*Natural History*, Bk. xxxv., Ch. 15) would appear to have covered a number of salts or their mixtures: he refers to methods of test by means of galls and pomegranate juice (the tannin of which would serve to indicate the presence of iron) to determine the qualities suitable for dyeing bright colours. In the 15th century the Turkish Mediterranean trade in dyed fabrics and wool, in which alum was employed as a mordant, amounted to a very large annual sum; but the preparation of native salts by lixiviation and evaporation and, later, that of potassium alum from the mineral alunite, a basic sulphate of alumina and potash which is found in a number of places in the Near East, was probably practised much earlier.

About the year 1460, John di Castro learned the art at Constantinople and began to make alum at Tolfa from an important local deposit of alunite which has remained in use to within the present century. The introduction of the manufacture into Italy (where it shortly afterwards became a papal monopoly) was announced as a great victory over the Turks. In England Sir Thomas Chaloner began the preparation of alum from the schists on his Yorkshire estate about the year 1600. Despite papal denunciation, the manufacture extended considerably, and the method continued largely unchanged down to about the middle of last century in the neighbourhood of Whitby and Guisborough, employing the Lias schists, and, at Hurler and Campsie, with mineral of very similar character from the base of the much older carboniferous limestone series of Scotland. This type of deposit also occurs in Belgium, Germany, the former Austrian empire and other countries, and has been worked for centuries for the same purpose in a number of places on the Continent.

Both the Italian method of manufacture from alunite and that from the alum schists were carried on, of necessity, in the absence of any extraneous supply of sulphuric acid, the production of which only assumed importance towards the end of the 18th and

early part of the 19th centuries. When alunite [$K_2SO_4 \cdot (Al_2O_3 \cdot SO_3)_3 \cdot 6H_2O$, if pure] is calcined at a temperature below that at which SO_3 would be driven off, a part of the alumina together with the major portion of the sulphuric acid and potash is rendered soluble in water, although much of the alumina remains insoluble. The solution obtained was basic and gave rise to a largely cubic alum which, although tending to be tinted by a very small amount of insoluble iron oxide, was otherwise of a very high degree of purity and was known as Roman alum.

Similarly the value of the Lias and other alum schists depended mainly upon their self-contained source of sulphuric acid. Much finely divided pyrites is present and also a varying proportion of carbonaceous matter and when subjected to slow combustion in very large heaps, over a period of many months, the pyrites gradually oxidized with the production of sulphurous and sulphuric acids and concurrent formation of the sulphates of iron and aluminium. The calcined material was systematically lixiviated in large stone or brick-built tanks, the liquor settled, concentrated by the aid of surface heat, and any excessive proportion of iron allowed to crystallize out as copperas. Very little natural potash is present in these schists and the addition of a potash salt, derived from kelp, wood ashes or other source, was necessary. The fine meal of alum octahedra first obtained was submitted to a second crystallization to purify it. In spite of the fact that from 80–130 tons of schist were required to produce one ton of alum, the process continued in successful competition with Roman alum for between two and three hundred years.

In 1845 the manufacture of alum in England was radically altered by the substitution, by Peter Spence, of the alum schists by aluminous shales from the coal-measures. These shales contained more alumina, less iron and some potash and, after regulated calcination, were found to be reasonably soluble in sulphuric acid. The weight of aluminous material required per ton of alum was reduced from about 100 tons to two-thirds of a ton, the time required for the process was shortened very greatly, and the old method of manufacture gradually died out. This process, in which the by-product ammonia from the coal-gas industry largely substitutes the potash salts hitherto employed, has since accounted for the major proportion of the world's output. Bauxite has also been used as a source of the alumina component.

Potash alum is again the principal alum of commerce and is largely obtained from the Italian mineral leucite, a double silicate of alumina and potash or soda. In the lava flows from certain extinct volcanoes in the Apennines, the leucite is almost entirely potassic and constitutes some 30–40% of the whole. The mineral is crushed, graded and subjected to electro-magnetic treatment for the separation of the gangue. The substantially pure leucite meal or grain is then treated with sulphuric acid in which its alumina and potash are soluble and the solution, which already contains these oxides in almost equi-molecular ratio, is crystallized and purified in the ordinary way.

Iron alum (ferric ammonium sulphate) is prepared technically to a small extent, but the only other alum of commercial importance is the chromium potassium sulphate salt which is obtained as a by-product from the reduction of potassium bichromate in the manufacture of alizarin.

BIBLIOGRAPHY.—For the older methods of obtaining alum: Ure's *Dictionary of Arts, Manufactures and Mines* (7th ed., 1878); also Geschwind's *Manufacture of Alum and the Sulphates of Alumina and Iron* (1901). (H. Sp.)

ALUMINA, the only aluminium (*q.v.*) oxide. It occurs as corundum, which is a hard colourless crystalline solid, as ruby, sapphire, topaz, etc. (tinted by other metallic oxides), and in bauxite (*q.v.*). Amorphous alumina may be obtained by ignition of aluminium hydrate, or aluminium sulphate, etc. Synthetic rubies are made by heating together alumina, barium fluoride and a trace of potassium dichromate. (See GEMS, ARTIFICIAL.) Alumina, when precipitated from a solution containing a colouring matter, will form an insoluble pigment, called a *lake*. It is also commonly used as a mordant in dyeing. Alumina is next in hardness to the diamond (see ABRASIVES), crystallizes in the rhombohedral system and has the chemical formula Al_2O_3 .

ALUMINIUM or **ALUMINUM**, a metallic element which owes its name to the Romans, who called certain salts, now believed to be the mixed sulphates of iron and aluminium, *alumen*. These salts were found in the volcanic districts washed by the Mediterranean and were much used in medicine and the dyer's art. In the 18th century it was first recognized that a salt with similar properties could be produced from clays by the action of sulphuric acid; and the base contained in clay, from which it was realized that this salt must be derived, was, in France, at first called *terre argilleuse*, but later *alumine*. In England this became *alumina*, whilst the Germans adhered and still adhere to the word *Thonerde*. Sir Humphry Davy, although he failed to isolate the metal of which it had been recognized that alumina was the oxide, suggested *aluminium* as a suitable name for it, a name still used in America, but elsewhere converted to the more euphonious *aluminum* (symbol Al, atomic number 13, atomic weight 27.1).

Occurrence and Ores.—Aluminium is not found in a metallic state in nature, a fact sufficiently explained by its great affinity for oxygen. Combined, however, it is one of the most widespread of the elements, only oxygen and silicon being more abundant in the earth's crust, of which it is computed that aluminium forms a 13th part. Its compounds exist in many forms, from mountainous masses to rare gems. Of these may be named the oxides, corundum, ruby and sapphire; their hydrates, gibbsite and bauxite; and their compounds with magnesium and beryllium, spinell and chrysoberyl respectively. The double fluoride of aluminium and sodium, cryolite or "ice-stone" is found in southern Greenland as a vast dyke in porphyritic granite. The sulphate of aluminium occurs in many volcanic districts, whilst, in combination with the sulphates of the alkali metals, it forms the natural alums. Of the phosphates only turquoise need be cited, whereas the silicates include such diverse materials as the micas and clays, garnets, topaz, the feldspars, etc. Many natural waters contain alumina, sometimes in considerable proportions, whilst it is found in the ash of numerous plants.

Despite this wide distribution the ore from which the metal is to-day derived is, with few exceptions, the hydrate bauxite, itself a decomposition product of silicate containing rocks, such as the granites, basalts, syenites, etc. Vast deposits of this material, suitable for the extraction of the metal, have now been located in every continent, so that a shortage is unlikely for many years to come. Yet continuous efforts (and some apparently on the point of success) are directed to making such silicates as feldspar, china clay and the leucites available for the purpose. Finally, we must note that cryolite, either natural or artificial, though not an ore, is indispensable in the present commercial production of the metal.

ISOLATION AND EXTRACTION

When in the middle of the 18th century it was recognized that alumina was the oxide of a metal, all means available at the time were employed, though unsuccessfully, to smelt it. Indeed, Lavoisier, in 1782, expressed the belief that alumina could not be reduced by carbon, a belief maintained until, almost a century later, the brothers E. H. and A. H. Cowles, heating alumina mixed with other metal oxides and carbon by electricity, produced aluminium alloys commercially. They failed, however, to win the pure metal and not until 1907 was it shown that alumina alone could be reduced by carbon though only at a temperature ($2,200^\circ \text{C.}$) at which the metal produced was volatilized and lost or recombined with the oxides of carbon formed. At the same time the function of the alloying metal used by them was found to be the prevention of this recombination and the absorption of the aluminium vapours set free.

Returning to 1809, we find Sir Humphry Davy passing an electric current derived from a voltaic pile through fused aluminium into iron molten in an atmosphere of hydrogen. Although there resulted an alloy of aluminium and iron in place of the metal he had hoped to isolate, Davy had thus accomplished the first and, perhaps, the greatest step toward the production of aluminium, for he had definitely proved that its oxide was reducible.

Abandoning electricity, which had failed Davy, H. C. Oersted

and after him F. Wöhler, attempted the displacement of aluminium from its chloride by the alkali metal, potassium. It is uncertain whether Oersted succeeded: it is certain that in 1827 Wöhler produced metallic aluminium as a grey powder and, subsequently, in metallic pellets. Twenty-five years later, F. Rose, substituting, for volatile aluminium chloride, the newly imported and more stable double fluoride, cryolite, and H. St. Clair Deville, replacing potassium by the cheaper sodium, converted Wöhler's laboratory method into successful technical processes, which were practised in several countries until both were alike swept from the field when the evolution of the dynamo made it possible to produce aluminium electrolytically.

A method, based on the power of electricity to split metal salts into their components, had been discovered many years before it was possible to apply it commercially. Earlier attempts to electrolyse aqueous solutions had failed because, as we now know, the aluminium produced at once recombined with water. In 1854, however, Robert Bunsen passed a current through a molten mixture of aluminium chloride and common salt, splitting the former into chlorine, which escaped, and aluminium which he collected as metallic beads. Bunsen's method was developed 30 years later into the process by which aluminium is produced today. Once more cryolite replaced the volatile chlorides and this led to a further step of the utmost importance. It was found that molten cryolite readily dissolves alumina and that a current passed through such a solution decomposes, not the cryolite, but the cheaper and more easily resolved alumina, thus economizing both power and material, and, as will be shown, making possible a continuous process. It was Paul Héroult in France and Charles Hall in America who, in the '80s made this great advance, the Frenchman as the result of an accident, the significance of which he had the wit to recognize and the energy to turn to account; the American as the result of a definite quest doggedly pursued.

Modern Method of Manufacture.—The processes evolved by Hall and Héroult were identical and have remained in all essentials unchanged. Carefully purified alumina is dissolved in molten cryolite and the solution is electrolysed, the heat necessary to fuse the cryolite being supplied by the electrolysing current,

FIG. 1.—ALUMINIUM EXTRACTION BY MEANS OF THE ELECTRICAL FURNACE

The alumina, or aluminium oxide is shown dissolved in molten cryolite at a temperature of 950° C. The oxygen given off combines with the carbon anodes, which are thus burnt away and must be constantly replaced. The pure molten aluminium sinks and is drawn off periodically

Since cryolite is excessively corrosive the operation is carried out in open-topped iron casings, thickly lined with carbon. The current is led into the furnace by a number of carbon blocks suspended in the bath and leaves through the furnace lining. Alumina is decomposed into aluminium and oxygen and the latter consumes the carbon anode blocks, forming gaseous oxides of carbon (see fig. 1). The operation is carried on at about 950° C. or far above the melting point of aluminium (659° C.) which is, therefore, liquid when produced. Being heavier than the electrolyte it sinks to the bottom of the bath, the current passing through it to the

lining, thence to the furnace casing and away. As the alumina is consumed fresh quantities are added and as the carbon anodes burn away they are replaced, whilst the aluminium is tapped from the furnace periodically, so that the process is practically continuous. The baths are about 1 ft. deep, 5 ft. long and 2½ to 3½ ft. wide. Heavy currents of from 8,000 to 20,000 amps. are used, the voltage for each bath, of which 40–50 are placed in series, being about 5·5–6·5. Theoretically, the voltage should be only 2·79 and 10,000 amps. should produce about 177 lb. of aluminium per day. In practice this becomes about 150 lb. and it takes 3½–3¾ h.p. to produce 1 ton of aluminium per year. Theory demands 1·88 tons of alumina per ton of aluminium and this figure is but very slightly exceeded, whilst about ½ ton of carbon is consumed. Theoretically no cryolite is used but in practice there are losses amounting to about 0·1 ton per ton of aluminium.

PROPERTIES

Form and Structure.—Aluminium when cast from the furnaces solidifies in crystal masses, as may be seen if an ingot be broken at temperatures just below the melting point. Mechanical working deforms and partly shatters the original crystals, but subsequent heating causes recrystallization. When the degree of deformation and temperature of heating are suitable, some crystal grains grow at the expense of others and, under carefully selected conditions, one grain alone may grow and thus convert large pieces of metal into a single crystal. Exaggerated grain size such as this is avoided in practice, metal showing this phenomenon being defective in mechanical properties.

Composition.—Whereas such metals as copper and zinc can be deposited electrolytically from aqueous solutions almost chemically pure, aluminium which can only be deposited from fused electrolytes carries with it whatever metallic impurities the raw materials and electrodes used in its manufacture contain. The best metal leaves the furnaces with not less than 0·2% of impurities, whilst commercial metal generally contains only 99–99·6% of aluminium. The remainder consists mainly of iron and silicon in approximately equal proportions, with 0·01–0·1% of copper derived from the furnace equipment. Small quantities of nitrogen are regularly found, as also of carbon, although the latter cannot be accurately estimated; but sodium, contrary to earlier statements, is never present in appreciable quantity. The same holds good of oxygen and aluminium oxide, but hydrogen may be a cause of serious trouble. Dissolved in overheated metal it separates on slow cooling, producing porosity, which can only be eliminated by remelting and so allowing the gas to escape. The following analysis (W. H. Withey) is typical of high grade commercial aluminium:

Iron	0·183
Silicon	0·154
Copper	0·026
Nitrogen	0·040
Zinc	0·006
Sodium	Trace
Carbon	Not estimated
Aluminium (diff.)	99·591

Until recently no practicable method of purifying aluminium was available. During the last few years several methods have, however, been elaborated and, by one, considerable quantities of refined metal have been made. A heavy alloy of aluminium and copper is melted under fused cryolite to which barium fluoride is added. When an electric current is passed from the alloy below to an electrode above, aluminium alone passes out from the alloy. In the reduction furnaces we have seen that aluminium sinks. Here, however, the gravity of the bath has been raised by the barium fluoride, so that the aluminium floats on the surface and can be removed. Metal containing 99·98% aluminium has been prepared in this way. The following is a typical analysis of purified aluminium:

Iron	0·014
Silicon	0·012
Copper	0·020
Zinc	0·00
Aluminium (diff.)	99·954

Physical Properties or Commercial Aluminium.—The specific gravity is 2.70–2.71. Hence, equal volumes of the common metals have the following relative weights: aluminium 1, magnesium 0.65, zinc 2.6, steel 2.9, brass 3, copper 3.25, nickel 3.25, lead 4.2. The specific gravity of aluminium at its melting point is about 2.40. Cast or annealed wrought aluminium breaks under a load of 11–13,000 lb. per sq.in., but when hardened by working under 22–28,000 lb. Hence the specific tenacity or breaking load for unit weight $\frac{(\text{tenacity})}{(\text{sp. gr.})}$, which largely determines the

relative values of light constructional materials, is 2 and 4 in the two cases, compared with 3.3 for hard copper, 4.2 for mild steel and 5.9 for tempered nickel steel. At high temperatures aluminium is very weak, whilst after being heated for a few hours to 350° C. work hardness is permanently lost. At 250° C. this takes longer whilst after 5 years at 200° C. and 100° C. respectively 50% and 86% of work hardness still remain. Aluminium ranks as a soft metal, its hardness being about half that of copper and zinc but double that of tin. The ductility and malleability of annealed aluminium are very high and it may, therefore, be drawn to the finest wire or beaten to the thinnest leaf. In tension a 2in. length may be elongated by 30% before fracturing, but heavy cold working reduces this figure to 3% or less. Elasticity is very low. Work hardened aluminium ceases to be elastic when loaded to 7–8,000 lb. per sq.in., and to 2–2,500 lb. when in the soft state. Moreover, as with other soft metals, the effect of loading develops slowly and recovery therefrom is very slow. Thermal expansion (0.000237 per degree from 10° C.–100° C.) is two and a half times that of steel, double that of nickel and one and a half times that of copper, whilst shrinkage on solidification is high (about 7%). Specific heat (about 0.24 from normal temperature to melting point) and latent heat of fusion (probably 90 calories per gram) are both high, so that notwithstanding the low melting point of 658.7° C. it requires much heat to melt aluminium. Heat conductivity (0.504 calories per second per c.c. per ° C.) is about three times that of tin, nickel and iron but little more than half that of copper and silver. Electrical conductivity is also high, namely about 60% of that of copper and resistivity (2.6–2.8 microhms per c.c.) therefore low. Aluminium is non-magnetic. In the electro-chemical series the position of aluminium is not quite certain. Probably it is less noble than all the common metals except magnesium and the alkali and alkaline earth metals.

The physical properties of the purest metal so far made by refining vary somewhat from those given above. It may be said that the strength and hardness are definitely lower, and that the melting point is about 1° C. higher and the electrical conductivity about 4% higher.

COMPOUNDS OF ALUMINIUM

Aluminium and Oxygen.—Aluminium (which is trivalent) forms one oxide—alumina (Al_2O_3). A film of this oxide normally covers the metal and upon this its character, its behaviour under chemical attack, indeed its whole utility may be said to depend. Generally invisible, the film may be seen if a thin foil of metal be heated for a prolonged period and then placed in hot nitric acid. The metal dissolves leaving the skin as glistening scales. Normally the thickness of the film is 0.0001mm., increasing twentyfold to 0.002mm. after prolonged heating of the metal. It is impervious to many reagents and it is due to this fact that so highly reactive a material as aluminium resists attack by many agencies to which, if this film be perforated, it immediately succumbs. Most important is the protection given against further attack by oxygen itself, but for which aluminium would oxidize in air as readily as sodium or potassium. This may be appreciated if a strip of aluminium be amalgamated with mercury. Some aluminium dissolves in the latter and, being no longer protected, immediately combines with oxygen and water vapour to form hydrated oxide, long fibres of which grow from the amalgamated surface. At high temperatures aluminium burns in air with great evolution of heat and the finely divided metal ignites readily, burning with a brilliant flame or even explosively, whilst, mixed with oxides of other metals and ignited, violent interaction takes

place, the aluminium depriving the other metal of its oxygen and itself burning to alumina. (See THERMIT.) In pure oxygen aluminium ignites at about 580° C. As we have seen, alumina occurs in many forms in nature. It is manufactured on a very large scale from the hydrate as a white crystalline powder for use in the production of aluminium. Fused in electric furnaces it forms alundum or artificial corundum, a valuable abrasive; whilst mixed with colour-giving oxides it yields artificial rubies, sapphires, etc.

Aluminium and Water.—Distilled water and the soft waters of peaty districts dissolve aluminium extremely slowly, but hard fresh waters and sea water cause rapid local corrosion of commercial metal unless air be entirely excluded. Recent work on the corrosion of aluminium seems to show it clearly due to local breakdown of the protective film and accumulation in the minute recesses formed in the surface of the metal, of hydrated oxide. This prevents access of the oxygen to the points it covers. Such differences are known to promote solution of metals. Corrosion by water may be slight or very serious, according to the state of the metal, its purity, temper and the perfection of its surface; the composition of the water; and the ease with which the products of corrosion can accumulate. Damp air merely causes a roughening of the surface. Stagnant or flowing water may cause superficial blisters, beneath which in time deep-seated cavities may form. These may, in turn, perforate the metal or disintegrate its surface.

Many methods have been suggested for obviating what is one of the chief disadvantages from which aluminium and its alloys suffer. Against atmospheric corrosion painting or varnishing is usually effective. Pure aluminium immersed in water may be effectively protected if connected to one of its more easily corrodible alloys, as iron boilers are protected by zinc plates. Aircraft parts are largely protected by strengthening the natural film upon them, to which end they are made the anodes in an electrolytic bath containing chromic acid.

The Hydrates.—All three possible hydrated oxides occur in nature, the monohydrate ($\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$) as diaspore, the dihydrate ($\text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$) as bauxite and the trihydrate ($\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) as gibbsite or hydrargillite. These hydrates behave both as bases, dissolving in acids to form salts, and as weak acids, dissolving in strong bases to form the aluminates. On this property the process most frequently used for the preparation of pure alumina depends. Bauxites, which contain iron and other impurities, are heated with caustic soda solution, whereby the aluminium hydrate is alone dissolved to form sodium aluminate. From the filtered solution the purified trihydrate is precipitated by various methods. On being heated aluminium hydrates give up water and are converted into alumina. When crystallized the trihydrate is insoluble in water but readily assumes the state of extremely fine division known as colloidal solution. In this state it absorbs many other bodies, notably dyestuffs, and its use as a mordant in dyeing, as well as for other purposes, is due to this property. Produced within the fibres of textiles the hydrate serves to fix the colouring matters which the fibres themselves are not capable of retaining.

Aluminium and Alkalis.—In the absence of water aluminium is not attacked by the fixed alkalis, but it dissolves in their caustic solutions to form aluminates, hydrogen being evolved. Solutions of sodium and potassium carbonate rapidly attack the metal but silicate of soda solutions do not and, moreover, prevent attack by the carbonates. For this reason commercial mixtures of carbonate and silicate of soda form excellent detergents for aluminium domestic utensils and are widely used for this purpose. Ammonium hydrate attacks aluminium much less actively than do the fixed alkalis and the only product is aluminium hydrate. To ammonium carbonate, aluminium is entirely resistant. At high temperatures gaseous ammonia is decomposed by aluminium, yielding aluminium nitride (AlN) which is also formed when aluminium burns in air.

Aluminium and Acids.—As might be assumed of so active a substance, aluminium may be caused to unite with almost all acids. Hydrochloric and the other halogen acids readily dissolve the metal under all conditions, although even to hydrochloric acid the very purest metal shows considerable resistance. Aluminium is

but very slowly dissolved by cold, fully concentrated nitric and sulphuric acids; rise of temperature and increasing dilution however, increase the rate of attack, especially by sulphuric acid. Dilute organic acids dissolve aluminium very slowly, those occurring naturally in foodstuffs so slowly that attack is generally negligible. It is particularly noteworthy that even where the pure acids dissolve the metal comparatively readily, the presence of other bodies in the foodstuff frequently inhibits their action altogether. Thus, a hot 0.2% solution of lactic acid attacks aluminium, but to milk of similar acidity aluminium is completely resistant. On the other hand, the presence of salts of those acids, which themselves readily attack aluminium, naturally enhances attack by organic acids. Vinegar mixed with common salt is much more active than vinegar alone. To concentrated organic acids aluminium is generally indifferent, but in the complete absence of water, boiling fatty acids as well as many alcohols and phenols rapidly dissolve aluminium, regardless of its purity. Minute traces of water suffice to prevent this form of attack, the cause of which has not yet been ascertained.

Aluminium is not attacked by sulphuretted hydrogen, ammonium sulphide or sulphur dioxide, but combines directly with fluorine, chlorine, bromine or iodine, to form the respective halides. At ordinary temperatures it is not attacked by oxides of carbon, but at high temperatures forms with them or with carbon the carbide Al_4C_3 , with nitrogen the nitride (AlN) and with sulphur the sulphide (Al_2S_3): these are decomposed by water yielding methane (CH_4), ammonia (NH_3) and sulphuretted hydrogen (H_2S) respectively. Similar combinations are formed with phosphorus, arsenic, etc.

As its position in the electro-chemical series indicates, aluminium decomposes many metallic salts, replacing the metal in them. Thus copper, silver, gold, etc., may be precipitated from solutions of their salts by aluminium. Finally, reactions at high temperatures similar to those described as occurring with metallic oxides take place with sulphides, sulphates and other metallic salts.

Aluminium Salts.—Salts of a great variety of acids are known, some only in aqueous solution. All are, when pure, colourless and have an astringent taste, and readily form mixed salts with the corresponding salts of other metals. In aqueous solution aluminium salts are hydrolysed (or partially resolved into hydrate and acid) to a very marked extent, the hydrate remaining colloidal dissolved. To this property the industrial importance of many aluminium salts is due. As the hydrate is a weak base these solutions show an acid reaction. The more important aluminium salts and their uses are: aluminium chloride ($AlCl_3$)—volatile crystals, readily decomposed by water vapour, of great importance in synthetic organic chemistry; aluminium sodium fluoride or cryolite ($3NaF \cdot AlF_3$), used as a solvent for alumina in the production of aluminium as well as in the manufacture of opaque glass and enamels; aluminium sulphate ($Al_2[SO_4]_3$)—widely used in the dyeing industry for mordanting, for coagulating impurities in water and in paper making, also as an astringent in medicine; the alums or mixed sulphates of aluminium and alkali metals—used for similar purposes; aluminium silicates and mixed silicates (see CLAY and FELSPAR); aluminium acetate ($Al[C_2H_3O_2]_3$)—existing only in solutions more strongly hydrolysed than those of any other aluminium salts used technically and for this reason of particular value to the dyer, to whom they are known as red liquor, also used as an antiseptic; aluminium oleate, palmitate, etc., used as thickeners for lubricating oils; ultramarine—a sulphide containing sodium and aluminium with silica occurring in nature as the much prized lapis lazuli, also manufactured on a large scale as a colouring matter, the laundry blue.

Physiological Properties.—Aluminium may be taken into the stomach without ill effect. Long series of experiments made with aluminium salts on animals and men indicate that, when ingested, aluminium does not pass through the wall of the stomach, is never found in the urine, but is totally rejected with the faeces. Under correct experimental conditions the organs of animals treated are found completely free from aluminium compounds.

Injected subcutaneously, however, aluminium salts, like those of

other metals, are toxic, although poisoning develops slowly and discontinuation of the injections is followed by recovery and clearance of the system. From the earliest times aluminium salts have been used in therapy, generally as astringents, but also as antiseptics and as mild caustics.

INDUSTRIAL ALLOYS

These alloys may be divided into two main classes: those in which small proportions of aluminium modify the properties of other metals and those in which other metals are added for this purpose to aluminium. The first category includes the aluminium bronzes (*q.v.*) which are mainly copper with up to 11% aluminium, aluminium amalgam (or aluminium dissolved in mercury) used in organic chemistry, and some aluminium solders which are mainly zinc or tin with varying proportions of aluminium. Finally, some *super-light alloys* consist of magnesium with small proportions of aluminium (see MAGNESIUM).

The present section deals with the second category, the light alloys of aluminium, containing 96–65% aluminium with copper, magnesium, manganese, nickel, silicon, tin and zinc.

Preparation and General Properties.—Preparation of these alloys follows customary lines where, as with zinc and tin, the alloying metal melts at as low a temperature as does aluminium. Where, as with copper, manganese and nickel, the melting point is much higher than that of aluminium and the latter would have to be seriously overheated before solution took place, it is customary first to prepare hardeners or alloys containing high proportions of the alloying metal. Such alloys not only dissolve readily in aluminium, the main bulk of which need not, therefore, be overheated, but can also be easily broken to sizes suitable for weighing and adding to the crucible. Special methods are adopted in the case of magnesium and silicon.

The light alloys are mechanically stronger than pure aluminium and especially have a much wider elastic range, but they are for the most part far less resistant to corrosion and have lower electrical and heat conductivities. Magnesium and silicon lower the specific gravity of aluminium, the other metals mentioned raise it.

Binary Alloys.—The useful light copper alloys contain 4 to 14% copper and their utility is due to the fact that the two metals form a definite compound, $CuAl_2$. Aluminium can hold 2% (recent work places this figure lower) of copper dissolved at ordinary temperatures, so that alloys containing up to this proportion are composed of one constituent only, a solid solution of copper in aluminium. If, however, an alloy with 5% of copper is held at 525° C. all of this copper becomes dissolved. Such alloys, slowly cooled, deposit their excess copper in large crystals of $CuAl_2$, mainly between the grains of the metal, which is strengthened thereby. If instead of being slowly cooled the hot alloy be suddenly quenched, the compound is not given time to separate and the alloy is still further strengthened but remains ductile. On the temperature being slightly raised the $CuAl_2$ is precipitated, but in a very finely divided state instead of in large crystals. As with many alloys here also such fine structures are accompanied by good mechanical properties. Thus the 5% alloy in the form of hard rolled sheet, as normally prepared, has a tenacity of 35–40,000 lb. but is brittle (3% elongation). Annealed the tenacity falls to 25,000 lb. whilst the elongation rises to 30%. Heat treated as described above, the tenacity may rise to 45–50,000 lb. whilst the ductility is only slightly impaired (25% elongation). As the specific gravity is about 2.8 such an alloy has the high specific tenacity of 7.5. A casting alloy containing 4–5% copper with other and minor constituents is widely used in America where it is known as No. 195. As cast, the tenacity is 17,000 lb. with 4% elongation. Heat-treated and quenched the tenacity rises to about 30,000 lb. with 8% elongation. Subsequent re-heating increases the tenacity to 40,000 lb., but lowers the elongation to 1.5%. Susceptibility to heat treatment is of great importance in the alloys of the duralumin type (*q.v.*) in which it has long been known but only recently explained. Copper in excess of 5% cannot be dissolved and alloys with more than this amount are increasingly brittle and can, therefore, not be wrought, although still suitable for castings. In America the alloy with 8% copper, known as No. 12,

is the most popular alloy for general automobile castings (crank cases, etc.) and similar purposes where high mechanical properties are a secondary consideration. It has a tenacity of 20,000 lb. with low ductility (1-2% elongation). The English alloy L.8 contains 11-13% copper and is specially suited and largely used for casting in permanent iron moulds and notably for the pistons of internal combustion engines. All these alloys corrode much more rapidly than pure aluminium. The alloy containing 1.5% manganese, known as 3.S, is widely used in America, where it is rolled into sheet, to be spun and pressed into cooking utensils. Without increased tendency to corrosion it is considerably stronger than pure aluminium, breaking under a load of 30,000 lb. when work hardened and 15,000 lb. when annealed. It apparently owes these properties to the simultaneous (eutectic) crystallization of pure aluminium and a compound, Al_3Mn , which produces a fine grained structure. No other binary manganese alloys are used.

The presence of silicon was formerly considered harmful in every way to aluminium. Recently, alloys with 11-13% have been introduced and promise to be the most valuable light casting alloys offered to engineers for a generation. Normally aluminium and silicon crystallize simultaneously in large plates, giving coarse structures and, with high silicon content, brittle and useless alloys. Various agencies, notably metallic sodium, have been found to cause the silicon to separate in an extremely fine state of division, even, as has been suggested, colloiddally (fig. 2). Such modified alloys have high tenacities (25-30,000 lb.), low specific gravity (2.66) and, therefore high specific tenacity (5). High ductility (12-14% elongation) is frequently attained in practice but cannot be relied on at present and the British Air Ministry specification only calls for not less than 7%. They are very fluid when molten and contraction on solidification is low (4%) whilst they resist corrosion well. Alloys containing up to 5% silicon, with or without the addition of other metals, are largely used when their great fluidity is of special advantage. Such alloys are as a rule not modified. Alloys with up to 35% zinc have been used. They are

BY COURTESY OF THE INSTITUTE OF METALS

FIG. 2.—ALUMINIUM SILICON ALLOY BEFORE AND AFTER MODIFICATION. The presence of silicon was formerly considered harmful to aluminium, since both crystallize simultaneously giving coarse structures and brittle and useless alloys. This is now overcome by causing the silicon to separate in an extremely fine state of division and the resulting alloys are of great utility. The illustration is drawn after microphotographs showing a magnification of about 140 diameters

very weak at high temperatures and, therefore, somewhat difficult to cast; they may, however, be rolled to sheets and bars of great strength.

Ternary and Quaternary Alloys.—Aluminium with 2% copper and 1% manganese is used in America for light forgings, having a tenacity of 27-28,000 lb. and 12% elongation. Alloys with 12-14% copper and 4-2% manganese maintain their strength well at high temperatures and are, therefore, specially suitable for the pistons of internal combustion engines. An alloy with 1% tin and 7% copper (the English 3.L.11) is considered specially suitable for articles subject to hydraulic pressure. In Europe, and especially England, copper and zinc alloys of aluminium are preferred for sand castings for automobile and general use. Three per cent. copper and 13% zinc (2.L.5) give a tenacity of 25,000 lb. with 3% elongation. The zinc content makes for cheapness

but raises the specific gravity to 3, so that the specific tenacity is only 3.7. With 20% zinc (L.28) these alloys can still be rolled and after suitable heat treatment have a tenacity of 55,000 lb. with 15% elongation and a specific tenacity of about 7.6. Alloys with copper and zinc are not well suited to casting in permanent moulds owing to weakness at high temperatures.

Aluminium with 7-9% copper and 1-3% nickel are favoured in America for pressure die casting. An alloy with 4% copper and 2% silicon known as *latalis* is used, mainly in Germany, in sheet form. Its mechanical properties approach those of duralumin.

Minute quantities of magnesium and silicon, when associated, confer on aluminium the property of age hardening. Their compound (Mg_2Si) is soluble to about 1.6% in solid aluminium at 580° C. but only to 0.5% at ordinary temperature. If, therefore, aluminium containing sufficient magnesium and silicon be held at high temperatures and suddenly quenched the excess magnesium silicide is thrown out, but not in its normal stable condition. In course of time (3-4 days), the newly precipitated crystals undergo secondary changes, which are not yet fully explained. When first quenched these alloys are soft and can be worked in various ways. During the subsequent changes they stiffen rapidly and, finally, give products with very great strength and other valuable characteristics. Magnesium silicide confers this property on various light alloys as well as on pure aluminium. (See DURALUMIN.)

THE ALUMINIUM INDUSTRY

In general, raw aluminium is converted into commodities by methods analogous to those used for other metals. The few radical differences are alone discussed here. Aluminium is melted in reverberatory furnaces or crucibles heated by oil; coke, gas or electricity, as circumstances and the scale of operations dictate. The pure metal requires no flux but a little zinc chloride is used with zinc alloys.

Ingot for rolling, extrusion, etc., are cast into iron moulds. Industrial castings are, however, prepared by three methods: large parts or those required in small numbers, in sand (sand castings); smaller parts required in numbers, by hand into permanent cast iron moulds (chill castings); whilst latterly considerable progress has been made in forcing the molten metal into closed moulds under pressure (die castings). Die castings are accurate to $\frac{1}{1,000}$ in. so that no subsequent machining is required, but very large numbers are required to justify the costly dies.

Rolling into sheets, foil, rods and sections, beating to leaf, extruding and drawing tubes and wire, spinning, pressing, riveting, machining, etc., follow customary practice, only minor modifications being demanded by the physical properties of aluminium or its alloys.

Annealing of work-hardened material is effected rapidly at 350° C. to 400° C., a temperature recognizable by the charring of a soft wood splinter drawn across the metal. Scaling does not take place so that no protection from the flame or furnace gases is necessary. Pickling or frosting is effected by immersion in a hot 10% caustic soda solution followed by dipping in dilute nitric acid. The alkali lightly attacks the surface of the metal giving a smooth, white finish. Forging is confined to certain alloys, notably duralumin (*q.v.*). Contrary to general opinion, soldered joints are easily made and are as strong, when first made, as those of other metals. They fail, however, without exception after a few weeks or even hours exposure to mild corrosives, because during soldering the solder dissolves some aluminium, forming alloys, generally of tin or zinc. These corrode so readily that they frequently disintegrate in damp air; but where complete protection can be afforded, as by painting, immersion in oil, etc., soldering is sometimes useful.

Welding, unlike soldering, demands no second metal and aluminium is successfully welded on a very large scale by several methods. At about 575° C. aluminium is very soft and two pieces hammered or pressed together at this stage unite as steel unites, giving very durable welds (hammer welding). The process is, however, difficult and expensive except on bars and wires and is not applicable to alloys. Using fluxes, principally mixtures of

ALUMINIUM

alkaline chlorides and fluorides, which dissolve the oxide film, the edges of two pieces of aluminium and many aluminium alloys may be molten by the oxy-acetylene flame and caused to flow together, whilst additional metal may be applied by means of an aluminium welding rod (autogenous welding). This method is widely used for making articles of sheet metal too large to be pressed or spun, such as petrol tanks, vats, stills, etc. Broken castings are also repaired by autogenous welding, sometimes without the use of flux.

Electrical welding is mainly confined to the butt-welding of rods and wires, the ends to be joined being pressed together while partially fused by the passage of a current. Spot-welding is also practised for special purposes.

Near its melting point aluminium loses all cohesion and the grains may be separated. Alternatively, the molten metal is run into specially constructed disintegrators, the product after solidification being classified by sieving. This type of powder is in Europe known as granulated aluminium, a name reserved in the United States for molten metal which has been passed through sieves into water. Aluminium bronze powder is produced from pure aluminium sheet scrap by progressive stamping in cast iron mortars with mechanically operated stamps. The finest particles are separated from the coarse by air classifiers and are then polished by rotating brushes in a sheet iron drum.

Approximately 2 tons of alumina, $\frac{1}{2}$ ton of carbon and 25,000 kilowatt hours are required to make a ton of aluminium. As about two tons of bauxite and several tons of chemicals and fuel are required for every ton of alumina, large quantities of materials have to be assembled. In most cases the production of the metal has become centred near the cheap sources of electricity, namely, hydro-electric power stations. As a notable exception, in northern Germany, steam stations fed by cheap and abundant lignite, provide the necessary motive power. Table No. 1 gives a picture both of the distribution of the producing countries and the movements of the metal when produced. From this it is seen that production is confined to 9 countries and that some 40% of the world's output is derived from the United States which, nevertheless, import in addition some 10-15% of what the world manufactures. From a comparison of the three columns in any year the amount converted into commodities in any country may also be gauged. Thus Norway, one of the largest producers, has but a poorly developed fabricating industry, whereas India and Japan, where no aluminium is produced, absorb large quantities for conversion into utensils and other manufactured products.

Finally, we may note that of the 750,000 tons of bauxite used for conversion into aluminium in 1925, the bulk was produced in 6 countries, viz., France, the United States, British Guiana, Italy, Dutch Guiana and Yugoslavia and none in Great Britain or Ireland.

The following table gives the world prices for ingot metal for the years 1924-27 inclusive:—

Country	England	Germany	United States
Year	£ per ton (2240 lb.)	R. Marks per kilo.	Cents per lb.
1924	110-118	2.24	27.03
1925	118	2.37	27.19
1926	118-105	2.28	26.09
1927	105	2.10	26.25

USES OF ALUMINIUM

The following is an indication of the main classes into which the applications of aluminium fall and shows upon what properties of the metal they depend.

Automobiles and Railway Carriages.—With increasing efforts to reduce the axle load of road vehicles and thereby to economize in upkeep, fuel and tyres, whilst improving acceleration, the uses of aluminium in the automobile industry grow continuously. Such parts as crank cases, differential housings, radiator tops, magneto bodies, brake shoes, etc., are regularly made as castings. Innumerable small cast parts also find their way into motor-car construction and in some cases dashboards, doors and windshields are similarly produced. Connecting rods forged from duralumin are used in some automobile engines and the cast aluminium piston is now standard for many types, since not only does the reduced weight entail greater efficiency and reduced vibration at high speeds, but the higher conductivity entails more rapid dissipation of the engine heat.

In the form of sheet, aluminium is widely used for the paneling of private automobiles and motor omnibus bodies, whilst mouldings, foot plates and floorings are largely of the same material.

With railway carriages, too, the tendency to reduce dead weight and so to increase effective loading is encouraging the use of aluminium. At present sheet metal panelling is the most usual form, but many small parts, such as brackets, door and window furniture, etc., are produced as castings, whilst in some cases seats and other larger parts are also made of light alloys, and the possibility of using special alloys for structural parts is being

seriously explored by experts for this and automotive purposes.

Aircraft, etc.—Aluminium is essential in aircraft construction and, in 1918, the Allies used 90,000 tons for this purpose. As far as the engines are concerned the same remarks hold good as for automobile engines. For the construction of complicated cowls, for fairings, seats, wind shields, etc., aluminium sheet has proved indispensable. For the petrol tanks of airships it has been used almost exclusively, whilst the frameworks of these machines have been built up of light aluminium alloys, chiefly duralumin (*q.v.*) and the same applies to some all-metal heavier-than-air machines.

For the moving parts of many small machines, such as gramophones, piano-players, typewriters, etc., the lightness of aluminium castings makes them particularly suitable, whilst for instruments and equipment which have to be carried aluminium is used wherever possible. In this category may be named photographic cameras, camping and military equipment, etc. Aluminium household furniture is now made on a large scale and finds its chief but by no means exclusive use in the tropics.

Aluminium Paint.—Its power of reflecting light to the extent of 65–75% determines the use of aluminium bronze powder as a paint. Suspended in a suitable vehicle, the minute flakes of which the powder consists have not only a great covering power but offer a brilliant and to many a pleasing surface. This is responsible for the great development in the use of aluminium paints, especially in America. The same property accounts for the use of aluminium powder for covering the fabrics used on aircraft. Sunlight is very destructive to such materials as also to the rubber gas bags of lighter-than-air machines. It has been found that the reflection of so large a part of this light by aluminium greatly lengthens their useful life. Aluminium bronze powder is also largely used in decorative printing. Upon this same property of reflecting light depends the use of aluminium leaf in decorative art. For this purpose it has almost entirely replaced silver leaf.

Electrical Industry.—Here aluminium plays a very large part to-day. For bare conductors and especially for overhead transmission lines, some of them hundreds of miles long, absorbing a thousand tons of metal or more, aluminium has largely replaced copper. In such cases the low tensile strength of aluminium is compensated for by interweaving with it high tensile steel wires. But for insulated wires the heavier cost of insulation due to the larger wire needed for a given current leaves copper supreme. During the copper famine of 1916–18 many electrical machines were made in Germany with aluminium windings, the individual wires being insulated only by thickening the natural film upon them. A special electrical application of aluminium is for transforming alternating into direct current. Aluminium in an electrolytic cell allows current to pass in one direction only, the reverse impulses being entirely suppressed.

The casings and housings of many electrical machines are aluminium castings. In some cases the fact that aluminium and its light alloys are non-magnetic is here of importance.

Foodstuffs Industries.—A great many of the uses to which aluminium is put depend upon the fact that aluminium salts are in no way poisonous. First among these must be named its use for cooking utensils, probably the largest single use of the metal in sheet form. For this purpose its high heat conductivity also commends it, as does the fact that it is uniform throughout its thickness, so that there is no fear of a protecting coating wearing off as is the case with tinned copper or enamelled iron. Upon the same properties depends the use of aluminium steam-jacketed pans in institutional kitchens and in the foodstuffs and chemical industries almost universally. For the wrapping of chocolates and other articles aluminium foil is now very largely used in place of tin foil; whilst in America aluminium collapsible tubes are made on a large scale for the packing of cosmetics, etc. The stamping of thin sheet into bottle and jar covers is alone an industry of no small importance.

The brewing industry makes wide use of aluminium in the form of vats and fermenting vessels, storage vessels for yeast and beer and tanks for the transport of beer by road and rail. In Europe, the dairy industry also uses aluminium widely in the form of

tanks and vessels for the storage, pasteurization and transport of milk and cream and for the vats used in cheese-making. For many other foodstuffs which are weakly acid, aluminium finds rapidly extending use, since much closer attention is being paid now than in the past to the presence of minute quantities of copper salts in materials destined for human consumption. Here may be specially named jam-making, fruit-preserving and meat-extracting and the production of high-grade gelatines.

Chemical Industry.—The resistance of aluminium to nitric acid has played an important part in the production of this acid and nitrates from the air, as well as in explosives factories, and some of the more recent processes for the production of acetic acid have also depended upon the possibility of using aluminium apparatus.

Many fine chemicals are made in aluminium vessels because the metal imparts no colour to them. For the same reason the palest varnishes are made in aluminium boilers.

The position of aluminium in the electro-chemical series and its consequent ability to displace more noble metals from solutions of their salts has been made use of. Copper is precipitated from solution in this way for analytical purposes and silver and gold have been recovered from cyanide solutions on a large scale.

Because sulphurous vapours do not attack aluminium it can be used to advantage where exposed to fumes and especially to furnace gases. Here, however, its low melting point is a factor to be guarded against. A special application of this property is the use of aluminium to coat other metals by the process known as calorizing. The parts to be coated are heated in aluminium powder (to which certain additions are made) in a non-oxidizing atmosphere. An aluminium alloy which is highly resistant to furnace gases forms on the surface of the metal object.

Its affinity for oxygen accounts for the use of aluminium in refining steel, small quantities being added with other ingredients as deoxidizers to the liquid steel. Its use in steel and iron welding depends on the same property. Aluminium powder, mixed with iron oxide and ignited, deprives the iron of its oxygen, developing so much heat that the resulting metallic iron is molten and may be cast round pieces of the same metal which it is desired to unite (*see THERMIT*). Many refractory metals can be similarly reduced from their oxides. Mixed with ammonium nitrate as a source of oxygen, granulated aluminium forms the powerful explosive ammonal and flash powders used in photography, and pyrotechnics are similarly made.

BIBLIOGRAPHY.—J. W. Mellor, *Treatise on Inorganic and Theoretical Chemistry*, vol. v. (1922), with an extensive bibliography. This valuable treatise should be consulted for the history, chemical and physical properties of aluminium and aluminium compounds. R. J. Anderson, *The Metallurgy of Aluminium and Aluminium Alloys* (1926), contains detailed accounts of the aluminium industry and its distribution, the production and fabrication of the metal and its alloys, and an excellent bibliography. It is profusely illustrated. M. G. Corson, *Aluminium and its Alloys* (1926) deals thoroughly with the alloys of aluminium and their structure, more particularly from the theoretical point of view. Edgar T. Panton's *The Working of Aluminium* is a good practical handbook. (R. S.)

ALUMINIUM BRONZE, the name originally given to an alloy containing 90% copper and 10% aluminium. Later, alloys with smaller percentages of aluminium and also those containing, in addition, 1%–4% of manganese and iron were included under the general term "aluminium bronzes." The maximum percentage of aluminium in industrial bronzes is 11%, as larger proportions entail excessive brittleness.

Aluminium bronzes are distinguished by their golden yellow colour, which has led to their extensive use for art-metal work. Mechanically they approach mild steel, being strong and ductile and lending themselves readily to rolling and forging. In fact the alloy containing 10% aluminium has been compared with 0.35% carbon Swedish Bessemer steel, by no means to the disadvantage of the former. When cast the 10% alloy has the following properties:

Elastic limit	25–30,000 lb. per sq. in.
Tensile strength	70–80,000 lb. per sq. in.
Elongation on 2"	20%
Brinell number	100

As in the case of steel, these properties may be greatly improved by suitable heat treatment.

Casting in sand offers some difficulties and sound castings are not easy to obtain. Casting in chills or by the centrifugal process yields excellent results, and great quantities of such castings are regularly produced. Machining is troublesome and special precautions are called for owing to its high strength and resistance to alternating stresses. The 10% bronze has been used with great success for the worm wheels of motor cars, many thousands of tons of metal having been cast for this purpose. Aluminium also confers on copper the property of resisting furnace and other sulphurous gases, so that these bronzes have proved themselves well adapted for utensils subjected to direct contact with flames. They have also been used with success to withstand attack by seawater and the acid waters found in some mines. Aluminium-manganese bronzes possess well defined magnetic properties.

For structure and mechanical properties see 8th and 9th Report of Alloys Research Committee, *Proceedings of the Institute of Mechanical Engineers* (1907, p. 57; 1910, p. 119). (R. S.)

ALUMINUM: See ALUMINIUM.

ALUM SHALES, sedimentary rocks, rich in alumina and iron pyrites.

ALUNDUM, a hard material belonging to the class of abrasives (*q.v.*), also used for the manufacture of laboratory apparatus. It is obtained by fusing bauxite (*q.v.*) in an electric furnace.

ALUNITE or **ALUMSTONE**, a mineral first observed in the 15th century at Tolfa, near Rome, where it is mined for the manufacture of alum. Extensive deposits are also worked in Tuscany and Hungary, and at Bulladelah in New South Wales. By repeatedly roasting and lixiviating the mineral, alum is obtained in solution, and this is crystallized out by evaporation. Alunite occurs as seams in trachytic and allied volcanic rocks, having been formed by the action of sulphurous vapours on these rocks. The white, finely granular masses somewhat resemble marble in appearance, and the more compact kinds from Hungary are so hard and tough that they are used for millstones. The hardness is 4 and the specific gravity 2.6. The mineral is a hydrated basic aluminium and potassium sulphate, $KAl_3(SO_4)_2(OH)_6$.

ALUNTUM, an ancient city of Sicily, (Gr. Ἀλόντιον, mod. S. Marco d'Alunzio), 6 m. from the north coast and 25 m. E.N.E. of Halaesa. It was probably of Sicel origin, though its foundation was ascribed to some of the companions of Aeneas. It suffered considerably at the hands of Verres. The abandoned church of S. Mark, just outside the modern town, is built into the *cella* of an ancient Greek temple, which measures 62 ft. by 18.

ALUR (Lur, Luri, Lurem), a Negro people of the Nile valley, living on the north-west coast of Albert Nyanza. They are akin to the Acholi (*q.v.*), speaking practically the same language.

ALURE, a rare architectural term for a passageway or gutter behind a parapet or a clerestory; sometimes written *valure* or *valoring*.

ALVA or **ALBA**, **FERNANDO ALVAREZ DE TOLEDO**, DUKE OF (1508–83), Spanish soldier, was descended from one of the most illustrious families in Spain. Selected for a military command by Charles V., he took part in the siege of Tunis (1535), and successfully defended Perpignan against the dauphin of France. He was present at the battle of Mühlberg (1547), and the victory gained there over John of Saxony was due mainly to his exertions. He took part in the subsequent siege of Wittenberg, and presided at the court-martial which tried the elector and condemned him to death. In 1552 Alva was entrusted with the command of the army intended to invade France, and was engaged for several months in an unsuccessful siege of Metz. He was then made commander-in-chief of all the emperor's forces in Italy. Success did not, however, attend his first attempts, and after several unfortunate attacks he was obliged to retire into winter quarters. After Charles's abdication he was continued in command by Philip II. Alva had subdued the whole Campagna, and was at the gates of Rome, when he was compelled by Philip's orders to negotiate a peace. One of its terms was that the duke of Alva should in person ask forgiveness of the haughty pontiff whom he had conquered. Proud as the duke was by nature, and

accustomed to treat with persons of the highest dignity, he confessed his voice failed him at the interview, and his presence of mind forsook him. Not long after this (1559) he was sent at the head of a splendid embassy to Paris to espouse, in the name of his master, Elizabeth, daughter of Henry, king of France.

In 1567 Philip sent Alva to the Netherlands to repress Protestantism there. Alva made the long march from Genoa at the head of a perfectly disciplined army of about 10,000 men. When he presented his credentials as captain-general of the Netherlands at Brussels it was clear that there remained to the regent, Margaret, Duchess of Parma, a mere shadow of power. Before the end of the year she resigned, and Alva succeeded her as governor-general and regent.

Alva's first care was to lure into his power Counts Egmont and Horn, two of the leaders of the malcontent nobles. They were seized and imprisoned, and in the next year brought to the block (June 2 1568). The new governor erected a tribunal, known officially as the "Council of Troubles," but popularly called the "Council of Blood." Alva himself presided, and reserved the decisions to himself. Of the seven Netherlanders who were members, five resigned after the nature of the operations of the court became clear. From the first the business was in the hands of Alva and two Spaniards, one of whom, Juan de Vargas, received the evidence collected from all over the country against heretics and malcontents. It was at the hands of the Council of Blood that Egmont and Horn received their sentence.

William of Orange, summoned before the Council, refused to acknowledge its competence, and left the country to raise troops to meet force with force. But the army of mercenaries which crossed the frontier under Louis of Nassau was destroyed by Alva without difficulty at Jemmingen (July 21 1568). Another army, led by William himself into Brabant, was foiled, and William withdrew and disbanded the force. By the failure of these two attempts Alva's position was made secure, and he was able to devote himself entirely to the crushing of the liberties of the towns and the destruction of heretics. In the terror which followed Alva himself boasted that 18,000 persons were executed, in addition to the numbers killed in battle or massacred after victory.

Alva made a serious blunder when, in desperate straits for money, he attempted in 1569 to levy a property tax and a 10% turnover tax on all sales, for by this measure he united Catholics and Protestants against him. The exiles from the Low Countries encouraged by the general opposition, fitted out a fleet of privateers, which harried the coast towns and seized Spanish ships at sea. On April 1, 1572 the "Sea-beggars" seized Utrecht. They captured Brielle and Flushing, and within a short time four of the northern provinces had declared for the Prince of Orange. Alva's preparations to oppose the gathering storm were made with his usual vigour, and he reduced Mons and Malines while his son Frederick, prior of Toledo, took Zutphen. The towns were sacked and the inhabitants maltreated, Catholic and Protestant alike. With the exception of Zealand and Holland, he regained all the provinces; and at last his son stormed Naarden, and, massacring its inhabitants, proceeded to invest the city of Haarlem, which, after standing an obstinate siege, was taken and pillaged (July 11, 1573).

Their next attack was upon Alkmaar, but the 2,000 burghers repulsed the 16,000 Spanish veterans sent against them with great loss, and Frederick was constrained reluctantly to retire. Alva's feeble state of health and continued disasters induced him to solicit his recall from the government of the Low Countries; a course which was not displeasing to Philip, who was now resolved to make trial of a milder administration. In Dec. 1573 Alva returned to Spain.

On his return he was treated for some time with great distinction by Philip. But he had many enemies, among them Philip's secretary, Antonio Perez. He was banished from court, and confined in the castle of Uzeda. Here he had remained two years, when the success of Don Antonio in assuming the crown of Portugal determined Philip to recall Alva. In 1581 he entered Portugal, defeated Antonio, drove him from the kingdom, and soon reduced the whole under the subjection of Philip.

Entering Lisbon, he seized an immense treasure, and suffered his soldiers, with their accustomed violence and rapacity, to sack the suburbs and vicinity. It is reported that Alva, being requested to give an account of the money expended on that occasion, sternly replied, "If the king asks me for an account, I will make him a statement of kingdoms preserved or conquered, of signal victories, of successful sieges and of 60 years' service." Alva died in Jan. 1583 at the age of 74.

BIBLIOGRAPHY.—See the *Life*, by Rustant (Madrid, 1751). His correspondence during his Flemish government has been published by M. Gachard (Brussels, 1850). See also *Coleccion de documentos inéditos para la historia de España*, vols. iv., vii., viii., xiv., xxii. and xxxv. (Madrid); and Motley's *Rise of the Dutch Republic* (1856).

ALVA, municipal burgh, Clackmannanshire, Scotland, 3½ m. N. of Alloa, terminus of a branch line of the L.N.E.R. Pop. (1931) 4,853. It is situated at the foot of three front peaks of the Ochils—West Hill (1,682ft.), Middle Hill (1,436ft.) and Wood Hill (1,723ft.). There are spinning-mills, and also manufactures of tweeds, tartans and other woollen goods. Silver, lead and other metals have been found in the hills, in small quantities.

ALVARADO, PEDRO DE (1495–1541), one of the Spanish leaders in the discovery and conquest of America, was born at Badajoz about 1495. He held a command in the expedition sent from Cuba against Yucatan in the spring of 1518, and returned in a few months, bearing reports of the wealth and splendour of Montezuma's empire. In Feb. 1519 he accompanied Hernando Cortez in the expedition for the conquest of Mexico, being appointed to the command of one of the 11 vessels of the fleet. He acted as Cortez's principal officer, and on the first occupation of the City of Mexico was left there in charge. When the Spaniards had temporarily to retire before the Mexican uprising, Alvarado led the rear-guard (July 1, 1520), and the *Salto de Alvarado*—a long leap with the use of his spear, by which he saved his life—became famous. He was engaged (1523–24) in the conquest of Guatemala, of which he was subsequently appointed governor by Charles V. In 1534 he attempted to bring the province of Quito under his power, but had to content himself with the exaction of a pecuniary indemnity for the expenses of the expedition. During a visit to Spain three years later, the governorship of Honduras was conferred upon him in addition to that of Guatemala. He died in Guatemala in 1541.

ALVAREZ, DON JOSÉ (1768–1827), Spanish sculptor, was born at Priego, in the province of Cordova, in 1768, the son of a stonemason. His full name was José Alvarez de Pereira y Cubero. In 1799 he obtained from Charles IV. a pension of 12,000 reals to enable him to visit Paris and Rome. In Paris he executed in 1804 a statue of Ganymede which is now in the sculpture gallery of the Prado, Madrid. Shortly afterwards he left Paris for Rome, where he remained till within a year of his death. His son, Don José Alvarez y Bougel (1805–29) also distinguished himself as a sculptor and a painter in his short life. One of the most successful works of the elder Alvarez was a group representing Antilochus and Memnon, now in the museum of Madrid. He also modelled portrait busts of Ferdinand VII., Rossini, and the duchess of Alba, which are remarkable for their vigour and fidelity.

ALVAREZ, DON MANUEL (1727–1797), Spanish sculptor, was born at Salamanca. He followed classical models so closely that he was styled by his countrymen *El Griego*, "The Greek."

ALVAREZ DO ORIENTE, FERNÃO (1540–1595), Portuguese poet, was born in Goa and served in the Indies. His incomplete *Lusitania Transformada* (1607) is an elegant pastoral poem.

ALVAREZ, FRANCISCO (c. 1465–1541?), Portuguese missionary and explorer, born at Coimbra, was sent in 1515 as secretary to Duarte Galvão and Rodrigo da Lima on an embassy to the negūs of Abyssinia (Lebna Dengel Dawit [David] II.). It was not until 1520 that he reached Abyssinia, where he remained six years, returning to Lisbon in 1526–27. In 1533 he was sent to Rome on an embassy to Pope Clement VII.

His account of his travels, *Verdadera Informaçam das terras do Presto Joam*, was published in 1540 at Lisbon, and translated into English (Sam. Purchas, *Pilgrimes*, part ii., 1625).

ALVAREZ, JUAN (1780–1867), Mexican general, was born at Concepción de Atoyac (now Ciudad Alvarez), territory of Guerrero, Mexico, on Jan. 27, 1780. He joined the revolt of Morelos against the Spanish rule in Nov. 1810, and in various battles in the ensuing struggle for independence won distinction as a cavalry officer. He had a prominent part in the revolt led by Santa Anna in 1822–23 which overthrew the Government of Iturbide and in 1847 served with the Mexican army in the war with the United States. He began the revolt of 1854–55 which ended the despotic rule of Santa Anna. His civil career began in 1849 when he became the first governor of the new State of Guerrero, formed from the territory of his birth. At Cuernavaca, on Oct. 4, 1855, he was made acting president of the republic but was unable to unite the conflicting elements among his followers. On Dec. 8, 1855, therefore, he transferred the office to Comonfort, and retired to his home at Acapulco. Throughout the period of the Second Empire, 1863–67, he was a resolute opponent of Maximilian. Though his liberal principles led him to participate in many revolutions, he was singularly free from selfish ambitions. He died on Aug. 21, 1867.

ALVAREZ QUINTERO, the name of two brothers, SERAFIN (1871–) and JOAQUIN (1873–), Spanish dramatists, born at Utrera. They revived in their graceful plays the traditional humour of Rueda's *pasos*. These plays deal chiefly with scenes of Andalusian life and include such subjects as *Los Galeotes* (1900), *El Patio* (1900), *Las Flores* (1901), *Malvaloca* (1912) and *La Calumniada* (1919). They are characterized by sparkling dialogue rather than by analysis of character or depth of thought.

See *Four Plays by Joaquín and Serafín Quintero*, tr. by Helen and Harley Granville-Barker (1928).

ALVEAR, MARCELO TORCUATO DE (1868–), Argentine politician, was born at Buenos Aires, on Oct. 4, 1868, the son of Torcuato de Alvear, several times mayor of Buenos Aires, and grandson of General Carlos de Alvear, first Argentine minister to the United States. After graduating from the University of Buenos Aires, he joined the Radical party, and in 1912, after study and travel in Europe, was elected to the lower house of the Argentine Congress, from the city, and then from the province of Buenos Aires. As a congressman he promoted social service legislation, notably for the improvement of housing and civil service conditions. He served as Argentine minister to France from 1916 until his election as president of Argentina in 1922, when he received a large majority over his opponent, Dr. Lisandro de la Torre. On the whole he continued the policies of his predecessor Hipólito Yrigoyen, though his long residence in Europe gave him a somewhat broader view of foreign affairs. As president he gradually became more influential in the affairs of the Radical party. He was succeeded as President by Dr. Hipólito Yrigoyen, Oct. 1928.

ALVEARY (Lat. *alvearium*), a beehive; used, like *apiarium*, figuratively for a collection of hard-working people, or a scholarly work (e.g., dictionary) involving bee-like industry. By analogy the term is used for the hollow of the ear, where the wax collects.

ALVENSLEBEN, CONSTANTIN VON (1809–1892), Prussian general, was born on Aug. 26, 1809, at Eichenbarleben in Prussian Saxony, and entered the Prussian guards from the cadet corps in 1827. He served with distinction in the campaign of 1866. In 1870, on the outbreak of war with France, von Alvensleben succeeded Prince Frederick Charles in command of the III. army corps which formed part of the II. German army commanded by the prince. Under their new general, the Brandenburg regiments forming the III. corps proved themselves collectively the best in the whole German army, with the possible exception of the Prussian guards, and, if Prince Frederick Charles may have the chief credit in training the III. corps, Alvensleben had contributed in almost equal degree to the efficiency of the Guard infantry, while his actual leadership of the III. corps in the battles of 1870 and 1871 showed him as a fighting general of the very first rank. The battle of Spicheren, on Aug. 6, was initiated and practically directed throughout by him, and in the confusion which followed this victory, for which the superior commanders were unprepared, Alvensleben showed his energy

and determination by resuming the advance on his own responsibility. This led to the great battles of Aug. 14, 16 and 18 around Metz, and again the III. corps was destined, under its resolute leader, to win the chief credit. Crossing the Moselle the instant that he received permission from his army commander to do so, Alvensleben struck the flank of Bazaine's whole army (Aug. 16) in movement westward from Metz. The III. corps attacked at once, and for many hours bore the whole brunt of the battle at Vionville. By the most resolute leading, and at the cost of very heavy losses, Alvensleben held the whole French army at bay while other corps of the I. and II. German armies gradually closed up. In the battle of Gravelotte, on the 18th, the corps took little part. Its work was done, and it remained with the II. army before Metz until the surrender of Bazaine's army. He became full general of infantry in 1873 and retired immediately afterwards. He died on March 28, 1892, at Berlin.

His brother, GUSTAV VON ALVENSLEBEN (1803-81), Prussian general of infantry, and another brother, ALBRECHT, COUNT VON ALVENSLEBEN (1794-1858), Prussian statesman, also had distinguished careers in the Prussian service.

ALVEOLATE, a word used in biology, to mean pitted like a honeycomb.

ALVERSTONE, RICHARD EVERARD WEBSTER, 1ST BARON (1842-1915), lord chief justice of England, was born Dec. 22 1842, being the second son of Thomas Webster, Q.C., and died Dec. 15 1915, at Cranleigh, Surrey. He was educated at King's College and Charterhouse schools, and Trinity College, Cambridge; was called to the bar in 1868, and became Q.C. only ten years afterwards. His practice was chiefly in commercial, railway, and patent cases until (June 1885) he was appointed attorney-general in the Conservative Government, in the exceptional circumstances of never having been solicitor-general, and not at the time occupying a seat in parliament. He sat in the House of Commons first for Launceston and then for the Isle of Wight. Except under the brief Gladstone administration of 1886, and the Gladstone and Rosebery cabinets of 1892-95, Richard Webster was attorney-general from 1885 to 1900. In 1890 he was leading counsel for *The Times* in the Parnell enquiry; in 1893 he represented Great Britain in the Bering Sea arbitration; in 1898 he discharged the same function in the matter of the boundary between British Guiana and Venezuela; and in 1903 he was one of the members of the Alaska Boundary Commission. He was well known as an athlete in his earlier years, having represented his university as a runner, and his interest in cricket and foot-racing was kept up in later life.

In the House of Commons, and outside it, he was throughout his political career prominently associated with church work; and his speeches were distinguished for gravity and earnestness. In 1900 he succeeded Sir Nathaniel Lindley as Master of the Rolls, being raised to the peerage as Baron Alverstone, and in October of the same year he was elevated to the office of lord chief justice upon the death of Lord Russell of Killowen. He retired in Nov. 1913.

See his *Recollections of Bar and Bench* (1914).

ALVORD, CLARENCE WALWORTH (1868-1928), American educator and historical scholar, was born in Greenfield, Mass., May 21, 1868. He graduated from Williams college in 1891 and pursued further studies at the universities of Berlin, Chicago and Illinois, from the last mentioned of which he received in 1908 the degree of doctor of philosophy. During the period 1891-1901 he devoted six years to teaching in preparatory schools. Entering the faculty of the University of Illinois in 1901 as instructor, he became in 1907 assistant professor, in 1909 associate professor and in 1913 professor of history, and occupied this chair until 1920. From 1920 to 1923 he was professor of history in the University of Minnesota. In 1906 he was appointed editor of publications for the Illinois State Historical Society. In this capacity he edited *Cahokia Records* (1906); with E. B. Greene, *Governors' Letters* (1909); *Kaskaskia Records* (1909); with C. E. Carter, *The British Series* (1915); and *Governor Edward Coles* (1920). His published writings include *Mississippi Valley in British Politics* (1917), which was awarded the Loubat prize of that year; *The*

Illinois Country, 1673-1818 (1920); *Lord Shelburne and the Founding of British-American Goodwill* (1925); and numerous contributions to historical journals. He died at Diano Marino, Italy, Jan. 27, 1928.

ALWAR, an Indian State in the Rajputana agency. Its configuration is irregular, the greatest length from north to south being about 80m., and breadth from east to west about 60m., with a total area of 3,141sq.m. The eastern portion of the State is open and highly cultivated; the western is diversified by hills and peaks, which form a continuation of the Aravalli range, from 12 to 20m. in breadth. These hills run in rocky and precipitous parallel ridges, in some places upwards of 2,200ft. in height. The Sabhi and Ruparel are the only streams of importance. The pop. in 1921 was 701,154. The maharaja Jai Singh, who succeeded in 1892 at the age of ten, represented India at the Imperial Conference in London in 1923. Alwar was the first Indian State to accept a currency struck at the Calcutta mint, of the same weight and assay as the imperial rupee, with the head of the British sovereign on the obverse. Imperial service troops are maintained, consisting of both cavalry and infantry, with transport.

The State was founded by the Rajput chieftain Pratap Singh (1740-91), and increased by his adopted son Bakhtawar Singh. The latter joined the British against the Mahrattas, and in 1803, after the battle of Laswari, signed a treaty of offensive and defensive alliance with the British Government.

The city of Alwar stands in a valley overhung by a fortress 1,000ft. above. It is surrounded by a rampart and moat, with five gates, and contains fine palaces, temples and tombs. The water-supply is brought from a lake 9m. distant. It has a school for the sons of nobles, founded to commemorate the Diamond Jubilee of Queen Victoria. Pop. (1921), 44,760.

ALYATTES, king of Lydia (609-560 B.C.), the real founder of the Lydian empire, was the son of Sadyattes, of the house of the Mermnadae. He carried on the war against Miletus begun by his father, until 604, when it was ended by a treaty of peace and alliance (Hdt. i. 18-23). He next came into conflict with the rising power of Media, but on May 28, 585, a pitched battle was interrupted by an eclipse of the sun (Hdt. i. 74). A peace was concluded, through the mediation of Babylon and Cilicia, which fixed the Halys as the boundary between the two kingdoms (Hdt. i. 102). Alyattes drove the Cimmerii (see SCYTHIA) from Asia, subdued the Carians, and took several Ionian cities (Smyrna, Colophon). He was succeeded by his son Croesus. His tomb still exists on the plateau between Lake Gygea and the River Hermus to the north of Sardis—a large mound of earth, with a substructure of huge stones. It was excavated by Spiegelthal in 1854, who found that it covered a large vault of finely cut marble blocks approached by a flat-roofed passage of the same stone from the south. The sarcophagus and its contents had been removed by early plunderers of the tomb, all that was left being some broken alabaster vases, pottery and charcoal. On the summit of the mound were large *phalloi* of stone (Hdt. i. 93).

See A. von Ölfers, "Über die lydischen Königsgräber bei Sardes," *Abh. Berl. Ak.*, (1858).

ALYPIUS, a Greek writer on music whose works, with those of six others, were collected and published with a commentary and explanatory notes (*Antiquae Musicae Auctores Septem*, Amstel., 1652), by Mark Meibomius (1630-1711). He is said to have written before Euclid and Ptolemy; and Cassiodorus arranges his *Introduction to Music* between those of Nicomachus and Gaudentius. The work consists solely of a list of symbols of the various scales and modes, and is probably only a fragment.

BIBLIOGRAPHY.—F. Bellermann, *Die Tonleitern und Musiknoten der Griechen* (1847); C. Fortlage, *Das musikalische System der Griechen* (Leipzig, 1847).

ALYPIUS OF ANTIOCH, a geographer of the 4th century, who was sent by the Emperor Julian into Britain as first prefect, and was afterwards commissioned to rebuild the temple of Jerusalem. Among the letters of Julian are two (29 and 30) addressed to Alypius, one inviting him to Rome, the other thanking him for a geographical treatise, which no longer exists.

See also Ammianus Marcellinus xxiii. i. §2.

ALYTES, a genus of batrachians of which the best known is the midwife toad, *Alytes obstetricans*, two inches in length, of dull greyish coloration, plump form with warty skin and large eyes. Although toad-like it belongs to another family, *Discoglossidae*. It inhabits most of western Europe. A second species, *A. cisternasi*, occurs also in Spain and Portugal.

Alytes is nocturnal and slow in its movements. It is thoroughly terrestrial. Towards evening it reveals its presence by a clear whistling note. The breeding season lasts throughout spring and summer, and the female spawns two, three or even four times in the year. Pairing and oviposition take place on land; the male seizes the female round the waist. The eggs are large and yellow, and produced in two rosary-like strings, as if strung together by elastic filaments continuous with the gelatinous capsules. After impregnation, the male twists them round his legs and returns to his usual retreat, resorting to a short immersion in the water during exceptionally dry nights. When the time for hatching has come, after about three weeks, the male enters the water; the larvae, measuring 14 to 17 millimetres, bite their way through their tough envelope, which is not abandoned by the father until all the young are liberated. The tadpoles grow to a large size before metamorphosis. (See LAMARCKISM.)

See R. Lydekker, J. T. Cunningham, G. A. Boulenger and J. A. Thomson, *Reptiles, Amphibia, Fish and Lower Chordata* (1912).

ALZEY, a town in Hesse, Germany, 20m. S.S.W. of Mainz. Pop. (1925) 9,200. It is mentioned in the *Nibelungenlied*. In 1277 it became an imperial city, and in 1620 was sacked by the Spaniards and in 1689 burnt by the French. During the Napoleonic wars it was annexed to France and in 1815 passed to the grand-duchy of Hesse-Darmstadt. It has considerable trade in wine.

ALZOG, JOHANN BAPTIST (1808–78), German theologian, was born at Ohlau, in Silesia, June 29 1808. Together with Döllinger, Alzog was instrumental in convoking the famous Munich assembly of Catholic scholars in 1863. He also took part, with Bishops Hefele and Haseberg, in the preparatory work of the Vatican Council, and voted in favour of the doctrine of papal infallibility but against the opportuneness of its promulgation.

Alzog's fame rests mainly on his *Handbuch der Universal-Kirchengeschichte* (Mainz, 1841, often reprinted under various titles; Eng. trans. by Pabisch and Byrne, *A Manual of Church History*, Cincinnati, 1874). Alzog was an active collaborator in the great *Kirchenlexicon* of Wetzer and Welte and was also the author of *Grundriss der Patrologie* (Freiburg, 1866, 4th ed. 1888), a scholarly work, though since superseded.

A full list of Alzog's writings is given in H. Hurter's *Nomenclator literarius recentioris theologiae catholicae*, vol. iii. For an account of his life see the funeral oration by F. X. Kraus, entitled *Gedächtnissrede auf Johannes Alzog* (Freiburg, 1879).

AMADIS DE GAULA. This famous romance of chivalry survives only in a Castilian text, but it is claimed by Portugal as well as by Spain. The date of its composition, the name of its author, and the language in which it was originally written are not yet settled. It is not even certain when the romance was first printed, for though the oldest known edition (a unique copy of which is in the British Museum) appeared at Sargasso in 1508, it is highly probable that *Amadis* was in print before this date; an edition is reported to have been issued at Seville in 1406. As it exists in Spanish, *Amadis de Gaula* consists of four books, the last of which is generally believed to be by the *regidor* of Medina del Campo, Garci Rodriguez de Montalvo. Montalvo alleges that the first three books were arranged and corrected by him from "the ancient originals," and a reference in the prologue to the siege of Granada points to the conclusion that the Spanish recast was made shortly after 1492; it is possible, however, that the prologue alone was written after 1492, and that the text itself is older. The number of these "ancient originals" is not stated, nor is there any mention of the language in which they were composed; Montalvo's silence on the latter point might be taken to imply that they were in Castilian, but any such inference would be hazardous. Three books of *Amadis de Gaula* are mentioned by Pero Ferrús who was living in 1379, and there is evidence that the romance was current in Castile more than a quarter of a

century earlier; but again there is no information as to the language in which they were written. Gomes Eannes de Azurara in his *Chronica de Conde D. Pedro de Menezes* (c. 1450) states that *Amadis de Gaula* was written by Vasco de Lobeira in the time of King Ferdinand of Portugal who died in 1383. Recent critics have inclined to the belief that *Amadis de Gaula* was written by João de Lobeira, a Galician knight who frequented the Portuguese court between 1258 and 1285, and to whom are ascribed two fragments of a poem in the Colocci-Brancuti (*Canzoniere* (Nos. 240 and 240^b), which reappears with some unimportant variants in *Amadis de Gaula* (book ii., chapter 2). The coincidence may be held to account in some measure for the traditional association of a Lobeira with the authorship of *Amadis de Gaula*; but, though curious, it warrants no definite conclusion being drawn from it. Against the Portuguese claim it is argued that the *Villancico* corresponding to João de Lobeira's poem is an interpolation in the Spanish text, that Portuguese prose was in a rudimentary stage of development at the period when—*ex hypothesi*—the romance was composed, and that the book was very popular in Spain almost a century before it is even mentioned in Portugal. Lastly, there is the incontrovertible fact that *Amadis de Gaula* exists in Castilian, while it remains to be proved that it ever existed in Portuguese. As to its substance, it is beyond dispute that much of the text derives from the French romances of the Round Table; but the evidence does not enable us to say (1) whether it was pieced together from various French romances; (2) whether it was more or less literally translated from a lost French original; or (3) whether the first Peninsular adapter or translator was a Castilian or a Portuguese. On these points judgment must be suspended. There can, however, be no hesitation in accepting Cervantes' verdict on *Amadis de Gaula* as the "best of all the books of this kind that have ever been written." It is the prose epic of feudalism, and its romantic spirit, its high ideals, its fantastic gallantry, its ingenious adventures, its mechanism of symbolic wonders, and its flowing style have entranced readers of such various types as Francis I. and Charles V., Ariosto and Montaigne.

AMADOU, a soft tough substance once frequently used as tinder, derived from *Polyporus fomentarius*, a fungus belonging to the group Basidiomycetes and growing upon old trees, especially the oak, ash, fir and cherry. The fungus is cut into slices and then steeped in a solution of nitre. Amadou is prepared on the continent of Europe, chiefly in Germany, but the fungus is a native of Britain. *Polyporus igniarius* and other species are also used, but yield an inferior product.

AMAKUSA, an island of about 200sq.m. off the west coast of the larger island of Kyushu in south Japan (32° 25' N., 130° E.). Its conformation is typical of that of the whole west flank of Kyushu, a hilly country broken up along north-east to south-west lines; and its terrace cultivation is that found not only in Kyushu but in most of south Japan. (See JAPAN.)

AMAL, the name of the noblest family among the Ostrogoths and that from which nearly all their kings were chosen. The family first appears in history in the 4th century A.D.

AMALARIC (died 531), king of the Visigoths, son of Alaric II., was a child when his father fell in battle against Clovis, king of the Franks (507). He was carried for safety into Spain, which country and Provence were thenceforth ruled by his maternal grandfather, Theodoric the Ostrogoth, acting through his vice-regent, an Ostrogothic nobleman named Theudis. In 522 the young Amalaric was proclaimed king, and four years later, on Theodoric's death, he assumed full royal power in Spain and a part of Languedoc, relinquishing Provence to his cousin Athalaric. He married Clotilda, daughter of Clovis; but his disputes

with her, he being an Arian and she a Catholic, brought on him a Frankish invasion, in which he lost his life in 531.

AMALASUNTHA or **AMALASUENTHA**, queen of the Ostrogoths (d. 535), daughter of Theodoric, king of the Ostrogoths, was married in 515 to Eutharic, an Ostrogoth of the old Amal line, who had previously been living in Spain. Her husband died, apparently in the early years of her marriage, leaving her with two children, Athalaric and Matasuentha. On the death of her father in 526 she succeeded him at Ravenna, acting as regent for her son; but being herself deeply imbued with the old Roman culture, she gave to that son's education a more refined and literary turn than suited the ideas of her Gothic subjects. Conscious of her unpopularity she banished, and afterwards put to death, three Gothic nobles whom she suspected of intriguing against her rule, and at the same time opened negotiations with the emperor Justinian with the view of removing herself and the Gothic treasure to Constantinople. Her son's death in 534 made but little change in the situation. Amalasuntha, now queen, invited her cousin Theodahad to share her throne. Theodahad, notwithstanding a varnish of literary culture, was a coward and a scoundrel. He fostered the disaffection of the Goths and, either by his orders or with his permission, Amalasuntha was imprisoned on an island in the Tuscan lake of Bolsena, where in the spring of 535 she was murdered in her bath.

The letters of Cassiodorus, chief minister and literary adviser of Amalasuntha, and the histories of Procopius and Jordanes give us our chief information as to the character of Amalasuntha.

AMALEKITES, an ancient tribe, or collection of tribes, belonging to the Bedouin type, familiar from their relations to Israel. Though Hebrew ethnology made them a subordinate branch of Edom (Gen. xxxvi. 12), and (if the text of Judges v. 14 and xii. 15 be correct) even connected them closely with the tribe of Ephraim, they are uniformly represented as enemies of Israel. Thus they harried the fugitives as they escaped from Egypt at the Exodus (Deut. xxv. 17-19), were included among the foes through whom a passage must be forced into southern Palestine from Kadesh (Num. xiv. 43-45), attacked Israel at Rephidim, where they were utterly defeated by Joshua (Exod. xvii. 8-16), were doomed to ultimate destruction by Balaam (Num. xxiv. 20), formed part of the coalition which Eglon, king of Moab, used to oppress Israel (Judges iii. 13), were included among the hordes of Bedouin raiders defeated by Gideon (Judges vi. 3, 33), were condemned to annihilation—put to the "herem"—by Saul (I. Sam. xv.), though the king incurred the anger of Yahweh by sparing Agag and the cattle; and yet enough of them survived to raid Ziklag in David's absence and to be overwhelmed by his vengeance (I. Sam. xxx.). It is not surprising to find them described as "enemies of Yahweh" (I. Sam. xxx. 26), and the objects of a perpetual "Jihād," or sacred war (Deut. xxv. 19, Ex. xvii. 16).

The district over which Amalek ranged lay to the south of Judah, probably between Kadesh and Hormah, though they may at times have been located further east; and the interchange of the ethnic with "Canaanites" and "Amorites" suggests that the Amalekites were merely one of Israel's traditional enemies of the older period. Even in one of the Psalms (lxxxiii. 7) Amalek is mentioned among the foes of Israel, and the same feeling is reflected still later in the book of Esther, where Haman the Agagite is pitted against Mordecai the Benjamite. The name of Amalek is celebrated in Arabian tradition, but the confused and conflicting stories are, for historical purposes, practically worthless.

AMALFI, town and archiepiscopal see, Campania, Italy, in the province of Salerno, 12m. W.S.W. by road from the town of that name, on the north coast of the Gulf of Salerno. Pop. (1921), 7,300. This picturesque old city lies at the mouth of a deep ravine, sheltered at the foot of Monte Cerreto (4,314ft.), in the centre of splendid coast scenery. The cathedral of San Andrea is in Lombard-Norman style (11th century) with façade in black and white stone, bronze doors executed at Constantinople before 1066, and campanile (1276). The conspicuous Capuchin monastery on the west with fine cloisters (partly destroyed by landslide, 1899) is now an hotel. Amalfi, first mentioned in the 6th century, soon became a naval power; in the 9th century it

shared with Venice and Gaeta the Italian trade with the East, and in 848 its fleet went to the assistance of Pope Leo IV. against the Saracens. It was then an independent republic with a population of some 70,000, but in 1131 it was reduced by King Roger of Sicily. In 1135 and 1137 it was taken by the Pisans, and rapidly declined in importance, though its maritime code, known as the *Tavole Amalfitane*, was recognized in the Mediterranean until 1570. It now has no harbour.

AMALGAM, the name applied to an alloy containing mercury, and said by Andreas Libavius to be a corruption of *μάλαγμα*; in the alchemists the form *algamala* is also found. Many amalgams are formed by the direct contact of a metal with mercury, sometimes with absorption, sometimes with evolution, of heat. Other methods are to place the metal and mercury together in dilute acid, to add mercury to the solution of a metallic salt, to place a metal in a solution of mercuric nitrate, or to electrolyse a metallic salt using mercury as the cathode or negative electrode. Some amalgams are liquids, especially when they contain a large proportion of mercury; others are crystalline. In some cases definite compounds have been isolated from amalgams, which may be regarded as mixtures of one or more of such compounds with mercury in excess. In general these compounds are decomposable by heat, but some of them, such as those of gold, silver, copper and the alkali metals, even when heated above the boiling point of mercury retain mercury and leave residues of definite composition. The use of tin amalgam in "silvering" mirrors, and of gold and silver amalgams in gilding and silvering has been almost completely superseded by chemical deposition of silver and by electroplating respectively. Cadmium and copper amalgam are employed in dentistry, and an amalgam of zinc and tin for the rubbers of electrical machines. The zinc plates of electric batteries are amalgamated in order to reduce polarization. Native amalgams of gold and silver have been found in various parts of the world, and the "amalgamation process" has been a standard method for the extraction of these two metals from their ores. Although it is still used to a reduced extent on gold ores, its use for silver ores is now practically obsolete.

AMALGAMATION. The term amalgamation, in its industrial sense, is one of a number of terms used to denote the process whereby previously independent and probably competing business concerns join forces and become a single concern conducted under a unified financial and industrial control. Amalgamation is usually spoken of as taking place between two firms only, and it is usually implied that the two previously independent establishments will continue, after the amalgamation, their outwardly separate existence. The four main methods of carrying out an amalgamation are:—

- (a) One of the two companies purchases the whole or a controlling part of the share capital of the other company;
- (b) A new company is formed to purchase the whole or a controlling part of the share capitals of both companies;
- (c) One company purchases outright the other's business; and
- (d) A new company is formed to purchase outright both businesses.

Amalgamation is a particular form of that movement towards combination and centralization in industry which has been an increasingly prominent feature of industrial development in all the principal industrial countries for well over half a century. (*See ASSOCIATIONS, INDUSTRIAL; COMBINES; see also the article TRUSTS.*)

(J. H.)

IN METALLURGY

Amalgamation is the process of extracting gold and silver from their ores by means of mercury. It depends on the fact that mercury, or quicksilver as it is usually called by metallurgists, "wets" and adheres to metallic gold and silver and penetrates them, forming pasty amalgams of a silvery colour. Particles of amalgam readily adhere to each other, and the aggregates become large and heavy enough to sink in running water which carries away sand and other earthy materials. Pieces of gold, if not too small, sink perfectly well of themselves and adhere to mercury or amalgam lying at the bottom of the stream, and gold ores have

been widely amalgamated on this principle. Coarse gold can be saved without the aid of mercury but finely divided gold is more likely to escape. Grains of silver naturally settle also, but most silver ores do not contain metallic silver. They contain compounds such as silver sulphide (silver combined with sulphur), and the compounds will not settle in water and must be decomposed to set free the silver before it can be amalgamated.

In amalgamation, ores are crushed to pulp in water and mixed with mercury with violent agitation in order to break up the mercury into minute globules and disperse them throughout the mass, and so enable them to be brought into contact with the gold or silver. Afterwards by dilution with water and gentle stirring, or by a running stream of water, the amalgam and surplus mercury are induced to coalesce and settle to the bottom, where they are caught in a pool of mercury or on the surface of copper plates to which they adhere. When the earthy matter has been washed away, the mixture of metals is put into filter bags and squeezed to remove the surplus mercury. The liquid mercury passes through, containing a minute quantity of gold and silver dissolved in it, and pasty amalgam containing from 25% to 50% of gold remains in the bag. The amalgam is heated in retorts (fig. 5), the mercury driven off as vapour, only to be condensed in a cool chamber for use again, and the gold and silver now nearly pure are melted down and cast into bars. Since all gold ores contain some silver and silver ores some gold, the bars consist of a mixture of gold and silver which are afterwards parted (*see* GOLD). The process is a very old one. The extraction of gold by mercury is mentioned by Pliny in his *Natural History*, and descriptions of amalgamation processes for both gold and silver are to be found in various 16th century treatises. The history of the process is given in detail by Percy.

Mercury may, however, become so excessively subdivided, as the result of too violent agitation or pounding, especially when mixed with grease or certain kinds of ore, that it becomes "floured" or "sickened." Floured mercury is a white powder like flour, although under the microscope it is seen to consist of minute globules of apparently ordinary mercury, heaped together. The globules will not coalesce and are carried away and lost in the tailings or refuse. They are generally separated only by films of air, and may be made to coalesce by the action of acids or in other ways entailing expense or loss. Again, although earthy matter and mercury have no action on each other, nevertheless mercury attacks and amalgamates copper, lead, zinc and some other metals, especially when they are present in the metallic state. The amalgam thus becomes debased and powdery so that part is lost and the remainder is costly to refine. There is also the case of ores which do not yield a reasonable percentage of their values when treated by amalgamation; these are called refractory and those which are amenable to amalgamation are described as free-milling.

Patio or Mexican Process.—Silver ore was ground by mule power in *arrastras* or shallow circular pits paved with stone (fig. 1). Large blocks of stone attached by beams to a central rotating post were dragged round the *arrastra* and reduced the ore to fine

FROM ROSE, "METALLURGY OF GOLD," BY PERMISSION OF C. GRIFFIN & CO., LTD.

FIG. 1.—THE ARRASTRA, USED BY THE MEXICANS FOR HUNDREDS OF YEARS IN GRINDING SILVER ORE

mud which was taken out and spread over a courtyard or *patio* in low heaps. It is then sprinkled with mercury and chemicals (common salt and copper sulphate) and mixed by mules which were driven over every part of the heaps. Complicated chemical reactions took place, never fully understood, the effect of which was to free the silver from its intractable compounds and enable it to be taken up by the mercury. The heaps were trodden by the mules every day or two until the amalgamation was complete, which might require a month. Lastly the material was agitated with water in large tubs and the mud run off through the plug holes. The amalgam found at the bottom was collected and treated as already described. The process was especially suitable for the silver ores of the dry barren districts of Mexico, where water and fuel are scarce, and was not finally displaced by the cyanide proc-

ess (*q.v.*) until early in the 20th century. It was used in the production of a large proportion of the world's silver for 350 years.

Pan Amalgamation Process.—The process was used for silver ores, especially in the United States, in the latter half of the 19th century and was superseded by the cyanide process and by smelting. Silver ore was ground to a fine paste with water in iron pans (fig. 2) by rotating iron shoes. The shoes were then raised a little, so as to agitate the pulp without further grinding, and mercury was sprinkled into the pan. The agitation was continued until amalgamation was completed, and the end in view was assisted by heating the pan with steam and by the addition of chemicals, especially common salt and copper sulphate. The amalgam was separated by diluting the pulp and stirring and finally by running off the charge into large settling tanks. The amalgamation pans were about 5ft. in diameter and the charge was 2,000 or 3,000lb.

FIG. 2.—AMALGAMATION PAN

Diagram of iron pan used for silver ore in the United States in 19th century. The ore, first ground with water, was then mixed with mercury

Complex silver ores containing minerals not amenable to amalgamation (such as the arsenical and antimonial sulphides, galena and blende) were roasted in furnaces at a red heat with common salt as a preliminary, when silver chloride was formed, a compound from which the silver can be extracted by mercury.

Amalgamation of Gold Ores.—This is simpler and cheaper than that of silver ores. The machine used more than any other for the reduction of gold ores between 1850 and 1925 was the stamp mill or battery (figs. 3 and 4). The stamp mill is worked on the principle of the pestle and mortar. The mortar is long and narrow, and ore, water and mercury are fed into it continuously. Five heavy steel stampers, each weighing from 800 to 2,000lb.,

are ranged in a row in one mortar. They are raised and let fall in succession, crushing the lumps of ore and driving the pulp through screens set in one side of the mortar. The old-fashioned wire screens were later replaced by perforated steel plates. The pulp coming from the screens is still further reduced by grinding in tube mills (rotating cylinders half filled with large pebbles, or lumps of unbroken ore) and then flows over sloping electro-silvered copper plates or tables, whose surface is amalgamated by rubbing with mercury. In older practice the copper plates were placed just outside the screens (fig. 4). The particles of gold adhere to the surface of the plate. Earlier still, amalgamated plates were fixed inside the mortar. The size and weight of stamps in the 20th century caused excessive loss of mercury by flouting and the addition of mercury and the fixing

FIG. 3.—STAMP AND MORTAR

California stamp, an improved form of the old German type of 1556, is used for crushing gold ore in all countries. The stamp is raised, slightly rotated and falls by gravity

of plates in the mortars were given up, the battery reverting to its original use as a mere crushing machine. Stamps forced down by springs or by power applied in various ways are sometimes used instead of gravity stamps and rotating crushers of various kinds (ball mills, tube mills, etc.) replace them in some new plants.

The clean-up takes place at intervals of a fortnight or a month. The stamps are hung up, the sand is washed away, the amalgamated plates are scraped and the amalgam after careful cleaning is squeezed and retorted as usual (fig. 5). The percentage yield of

gold varies with the conditions and the nature of the ore. Coarse gold is easily caught, but finely divided gold escapes in great part. Generally about 60% of the gold in the ore was recovered by amalgamation, and the remainder by cyanide. Ores containing only ½ oz. gold or even less per ton of ore have been treated at a profit.

On the Rand, amalgamation on copper plates had been generally discarded by 1925, owing to the difficulty of preventing the theft

FIG. 4.—GENERAL SECTION OF A GOLD STAMP MILL ON A HILL-SIDE, SHOWING SUPPLY OF ORE AND ITS PASSAGE THROUGH THE MACHINES

by Kafirs of the amalgam and the danger from mercury poisoning. Instead of passing the crushed ore from the tube mills over amalgamated plates it is concentrated on a surface of corduroy, which retains the heavy particles including all coarse gold. This is a reversion to the primitive practice of the gold-diggers of California in 1849 who used their blankets in concentrating gold sands. At intervals the corduroy is taken up and washed in boxes and the coarse gold is extracted from the contents of the boxes by further concentration. The fine gold left in the ore is extracted in the cyanide plant. The corduroy also catches osmiridium and other valuable metals of the platinum group which had previously been lost. The changes on the Rand appear to foreshadow the end of the old amalgamation process. Amalgamation on copper

AMALRIC, the name of two kings of Jerusalem. **AMALRIC I.**, king from 1162 to 1174, was the son of Fulk of Jerusalem and the brother of Baldwin III. He was twice married; by his first wife, Agnes of Edessa, he had issue a son and a daughter, Baldwin IV. and Sibylla; while his second wife, Maria Commena, bore him a daughter Isabella, who ultimately carried the crown of Jerusalem to her fourth husband Amalric of Lusignan (Amalric II.).

The reign of Amalric I. was occupied by the Egyptian problem. It became a question between Amalric and Nureddin which of the two should control the discordant viziers who vied with one another for the control of the decadent caliphs of Egypt. For some five years a contest was waged between Amalric and Shirkuh (Shirkuh), the lieutenant of Nureddin, for the possession of Egypt. Thrice (1164, 1167, 1168) Amalric penetrated into Egypt; but the contest ended in the establishment of Saladin, the nephew of Shirkuh, as vizier—a position which, on the death of the puppet caliph in 1171, was turned into that of sovereign. The extinction of the Latin kingdom then seemed imminent, and envoys were sent to the West with anxious appeals for assistance in 1169, 1171 and 1173. But though in 1170 Saladin attacked the kingdom and captured Aila on the Red Sea, the danger was not so great as it seemed. Nureddin was jealous of his over-mighty subject, and his jealousy bound Saladin's hands. This was the position of affairs when Amalric died, in 1174; but, as Nureddin died in the same year, the position was soon altered and Saladin began the final attack on the kingdom. Amalric I., the second of the native kings of Jerusalem, had the qualities of his brother Baldwin III. (*q.v.*). He was something of a scholar, and it was he who set William of Tyre to work. He was perhaps still more of a lawyer; his delight was in knotty points of the law, and he knew the *Assises* better than any of his subjects.

William of Tyre is our original authority: see xix. 2-3 for his sketch of Amalric. Röhrich narrates the reign of Amalric I., *Geschichte des Königreichs Jerusalem*, c. xvii.-xviii.

AMALRIC II., king from 1197 to 1205, was the brother of Guy of Lusignan. He married Isabella, the daughter of Amalric I., by his second marriage, and became king of Jerusalem in right of his wife in 1197. In 1198 he was able to procure a five years' truce with the Mohammedans, owing to the struggle between Saladin's brothers and his sons for the inheritance of his territories. The truce was disturbed by raids on both sides, but in 1204 it was renewed for six years. Amalric died in 1205. The kingdom of Cyprus, which he had inherited from his brother, passed to Hugh, his son by an earlier marriage; while that of Jerusalem fell to Maria, the daughter of Isabella by her previous marriage with Conrad of Montferrat.

AMALRIC OF BENA (Fr. AMAURY) (d. c. 1204-1207), French theologian, who taught philosophy and theology at the University of Paris, and enjoyed a great reputation as a subtle dialectician. His lectures developing the philosophy of Aristotle attracted a large circle of hearers. In 1204 his doctrines were condemned by the university, and, on personal appeal to Pope Innocent III., the sentence was ratified, Amalric being ordered to return to Paris and recant his errors. His death was caused, it is said, by grief at the humiliation to which he had been subjected. In 1209 ten of his followers were burned before the gates of Paris, and Amalric's own body was exhumed and burned. The doctrines of his followers, known as the Amalricians, were formally condemned by the fourth Lateran Council in 1215.

Amalric appears to have derived his philosophical system from Erigena (*q.v.*), whose principles he developed in a one-sided and strongly pantheistic form. Three propositions only can with certainty be attributed to him: (1) that God is all; (2) that every Christian is bound to believe that he is a member of the body of Christ, and that this belief is necessary for salvation; (3) that he who remains in the love of God can commit no sin. These three propositions were further developed by his followers, who maintained that God revealed Himself in a threefold revelation—the first in Abraham, marking the epoch of the Father; the second in Christ, who began the epoch of the Son; and the third in Amalric and his disciples, who inaugurated the era of the Holy Ghost.

Under the pretext that a true believer could commit no sin, the Amalricians indulged in every excess, and the sect does not appear to have long survived the death of its founder.

See W. Preger, *Geschichte der deutschen Mystik im Mittelalter* (Leipzig, 1874, i. 167-173); Hauréau, *Hist. de la phil. scol.* (Paris, 1872); C. Schmidt, *Hist. de l'Église d'Occident pendant le moyen âge* (Paris, 1885); Hefele, *Conciliengesch.* (2nd ed., Freiburg, 1886).

AMALTEO, the name of an Italian family belonging to Oderzo, Treviso, several members of which were distinguished in literature. The best known are three brothers, Geronimo (1507-74), Giambattista (1525-73) and Cornelio (1530-1603), whose Latin poems were published in one collection under the title *Trium Fratrum Amaltheorum Carmina* (Venice, 1627; Amst., 1689). The eldest brother, Geronimo, was a celebrated physician; the second, Giambattista, accompanied a Venetian embassy to England in 1554, and was secretary to Pius IV. at the council of Trent; the third, Cornelio, was a physician and secretary to the republic of Ragusa.

AMALTEO, POMPONIO (1505-1584), Italian painter of the Venetian school, was born at San Vito in Friuli. He was a pupil and son-in-law of Pordenone, whose style he closely imitated. His works consist chiefly of frescoes and altar-pieces and many of them (e.g., in the church of Santa Maria de' Battisti, at San Vito) have suffered greatly from the ravages of time.

AMALTHEIA, in the earlier Greek mythology, the foster-mother of Zeus. She is sometimes represented as the goat which suckled the infant god in a cave in Crete, sometimes as a nymph of uncertain parentage, who brought him up on the milk of a goat. This goat having broken off one of its horns, Amaltheia filled the horn with flowers and fruits and presented it to Zeus, who placed it, together with the goat, amongst the stars. According to another story, Zeus himself broke off the horn and gave it to Amaltheia, promising that it would supply in abundance whatever she desired. Amaltheia gave it to Achelous (her reputed brother), who exchanged it for his own horn which had been broken off in his contest with Heracles for the possession of Deianeira. Speaking generally, it was regarded as the symbol of inexhaustible riches and plenty, and became the attribute of various divinities and of rivers as fertilizers of the land. Cretan coins represent the infant Zeus being suckled by the goat; other Greek coins exhibit him suspended from its teats or in still other carried in the arms of a nymph. (Ovid, *Fasti*, v. 115; *Metam.*, ix. 87.)

AMA NDEBELE, a South African group of peoples. See NDEBELE.

AMANITA. The amanitas include some of the most showy representatives of the Agaricaceae or mushroom order of fungi (q.v.). In the first stages of growth, they are completely enveloped by an outer covering called the veil. As the plant develops the veil is ruptured; the lower portion forms a sheath or volva round the base of the stem, while the upper portion persists as white patches or scales or warts on the surface of the cap. The stem usually bears an upper ring of tissue, the remains of an inner veil, that stretched from the stem to the edge of the cap and broke away from the cap as the latter expanded. The presence of the volva, and the clear white gills and spores, distinguish this genus from all other agarics. They are beautiful objects in the autumn woods; *Amanita muscaria*, the fly fungus, formerly known as *Agaricus muscarius*, being especially remarkable for its bright red cap covered with white warts. Others are pure white or of varying shades of yellow or green. Several of the species are exceedingly poisonous.

AMANUENSIS, one who writes, from dictation or otherwise, on behalf of another (from Lat. *servus a manu*, slave of the hand). An amanuensis differs from a secretary in that, as a rule, he is a copyist only.

AMANULLAH KHAN (1892-), Amir of Afghanistan, was born June 1, 1892, being the third son of Habibullah Khan by his principal wife, Ulya Hazrat. On Feb. 20, 1919, Habibullah Khan was assassinated, whereupon his brother, Nasrullah Khan, seized the reins of government. Six days later, however, Amanullah Khan declared himself Amir. In Aug. 1919, following fighting between British troops and Afghans, the new Amir successfully negotiated a treaty of peace by the terms of which Afghanistan was left officially free and independent. From this time onward the Amir consistently adopted a policy of westernization. He even went so far as to advocate the emancipation of women by female education, which roused the opposition of the Mullahs and was one of the causes of the rebellion which broke out in Khost in 1924. (See AFGHANISTAN.) In the winter and spring of 1927-28 the Amir and his consort visited the principal European States. On his return, he introduced unpopular reforms, causing a revolt late in 1928. Amanullah abdicated on Jan. 14, 1929, and went to Europe in June.

AMAPALA, the Pacific port of Honduras, Central America. Population, about 3,000. Amapala is located on Tigre island, in the Gulf of Fonseca, and passengers and freight to and from the interior are carried on barges or launches to San Lorenzo, on the mainland, the terminus of the highway to Tegucigalpa and the interior.

AMARANTH or **AMARANT**, a name chiefly used in poetry, and applied to certain plants which, from not soon fading, typified immortality (from the Gr. *ἀμάραντος*, unwithering).

The plant genus *Amarantus* (of the family Amarantaceae) contains several well-known garden plants, such as love-lies-bleeding (*A. caudatus*), a native of India, a vigorous hardy annual, with dark purplish flowers crowded in handsome drooping spikes. Another species, *A. hypochondriacus*, is prince's feather, another Indian annual, with deeply-veined lance-shaped leaves, purple on the under face, and deep crimson flowers densely packed on erect spikes. "Globe amaranth" belongs to an allied genus, *Gomphrena*, and is also a native of India. It is an annual about 18 in. high, with solitary round heads of flowers; the heads are violet from the colour of the bracts which surround the small flowers.

In North America upwards of 30 species of amaranth occur, chiefly in the southern and southwestern United States, several of which are introduced weeds, mostly from tropical America. Among the most widely distributed are the green amaranth or rough pigweed (*A. retroflexus*), the red amaranth or pilewort (*A. hybridus*), the spiny amaranth (*A. spinosus*), the prostrate amaranth (*A. blitoides*) and the tumble-weed (*A. graecizans*), found almost throughout the continent except the far north.

In ancient Greece the amaranth (also called *χρυσάνθεμον* and *ελίχρυσον*) was sacred to Ephesian Artemis. It was supposed to have special healing properties, and as a symbol of immortality was used to decorate images of the gods and tombs. In legend, Amarynthus (a form of *Amarantus*) was a hunter of Artemis and king of Euboea; in a village of Amarynthus, of which he was the eponymous hero, there was a famous temple of Artemis Amarynthia or Amarysia (Strabo x. 448; Pausan. i. 31, p. 5).

See Lenz, *Botanik der alt. Griech. und Röm.* (1859); J. Murr, *Die Pflanzenwelt in der griech. Mythol.* (1890).

AMARAPURA, a suburb of Mandalay, Burma; pop. (1921) 8,497. The town was founded in 1783 to form a new capital about 6 m. to the north-east of Ava. In 1810 it was estimated to contain 170,000 inhabitants; but a fire in that year and the removal of the native court to Ava in 1823 caused a decline. In 1827 its population was estimated at only 30,000. An earthquake in 1839 destroyed the greater part of the city. It was finally abandoned in 1860, when King Mindön occupied Mandalay. Amarapura was laid out on much the same plan as Ava. The ruins of the city wall, now overgrown with jungle, show it to have been a square with a side of about three-quarters of a mile in length. At each corner stood a solid brick pagoda about 100 ft. high. A celebrated temple, adorned with 250 lofty pillars of gilt wood, contained a colossal bronze statue of Buddha. The remains of the former palace of the Burmese monarchs still survive in the centre of the town. Amara-

pura was defended by a rampart and a large square citadel, with a broad moat, the walls being 7,000 ft. long and 20 ft. high, with a bastion at each corner. The Burmans know it now as Myohaung, "the old city." It has a station on the Rangoon-Mandalay railway, and is the junction for the line to Maymyo and Lashio and for the Sagaing-Myitkyina railway. Amarapura is known to the Burmans as Taung-myo, "the southern city," as distinguished from Mandalay, the Myauk-myo, or "northern city."

AMARAR (UM 'AR'AR OR BENI 'AMIR), a tribe of African "Arabs" inhabiting the mountainous country on the west side of the Red Sea from Suakin northwards towards Kosseir. The tribe is divided into four great families: (1) Weled Gwilei, (2) Weled Aliab, (3) Weled Kurbab Wagadab and (4) the Amarar proper of the Ariab district. They claim to be of Koreish blood.

See *Anglo-Egyptian Sudan*, edited by Count Gleichen (London, 1905); Sir F. R. Wingate, *Mahdism and the Egyptian Sudan* (London, 1891); A. H. Keane, *Ethnology of Egyptian Sudan* (London, 1884); H. A. MacMichael, *History of the Arabs of the Sudan* (1922).

AMARA SINHA (c. A.D. 375), Sanskrit grammarian and poet. He is said to have been "one of the nine gems that adorned the throne of Vikramaditya," and according to the evidence of Hsüan Tsang, this is the Chandragupta Vikramaditya that flourished about A.D. 375. The only work of his which survives is the *Amara-Kosha* (Treasury of Amara), a vocabulary of Sanskrit roots, in three books, and hence sometimes called *Trikaṇḍa* or the "Tripartite." It contains 10,000 words, and is arranged, like other works of its class, in metre, to aid the memory.

The first chapter of the *Kosha* was printed at Rome in Tamil character in 1798. An edition of the entire work, with English notes and an index by H. T. Colebrooke, appeared at Serampore in 1808. The Sanskrit text was printed at Calcutta in 1831. A French translation by A. L. A. Loiseleur-Deslongchamps was published at Paris in 1839.

AMARAVATI, a ruined city of India in the Guntur district of the Madras presidency, on the south bank of the Kistna river, 62 m. from its mouth, a centre of the ancient Buddhist kingdom of Vengi, with a famous *stupa* (sepulchral monument). Its elaborate carvings illustrate the life of Buddha. Some are preserved in the British Museum; others in the museum at Madras. Amaravati has been identified with Hsüan Tsang's To-na-kie-tse-kia and with the Rahmi of Arab geographers. Subsequent to the disappearance of Buddhism from this region the town became a centre of Sivaism.

AMARI, MICHELE (1806-1889), Italian orientalist and patriot, born at Palermo. He joined the Carbonari, and had to leave Italy because he had written a work on the Sicilian Vespers, entitled *Un periodo delle storie Siciliane del XIII. Secolo* (1839), containing many political allusions reflecting on the Bourbon Government of Naples. As a refugee in Paris he divided his time between political work and mental studies. The revolution of 1848 found him in Sicily once more, but on the restoration of the Bourbons he was once more an exile. He returned to Italy in 1859, and taught Arabic at Pisa and afterwards at Florence. A strong supporter of Cavour, he was minister of education in the Farini and Minghetti cabinets. On the fall of the latter in 1864, he resumed his chair at Florence, where he lived until his death in 1889.

His interest in Arabic studies had been first awakened by French translations of Arabic works on his native island, and his principal work is connected with the history of Sicily. This book, *La Storia dei Musulmani in Sicilia*, was begun in 1844, and the fourth and last volume was printed in 1873. He is still the standard authority on the Muslim rule in Sicily.

Even more important are his collections of Arabic sources for the history of Sicily: *Biblioteca Arabo-Sicula; con appendice* (Leipzig, 1857-75), Italian trans. (Rome, 1880); *I diplomati arabi del archivio fiorentino* (Florence, 1863).

BIBLIOGRAPHY.—See A. d'Ancona, *Carteggio di Michele Amari coll'elogio di lui* (Turin, 1896); Oreste Tommasini's essay in *Scritti di storia e critica* (Rome, 1891); and *Centenario della nascita di Michele Amari* (Palermo, 1910), which contains valuable additions to the *Biblioteca*.

AMARILLO, a city of Texas, U.S.A., about 250 m. W. of Oklahoma City, at an altitude of 3,660 ft.; the county seat of Potter county. It is on Federal highways 66, 164, 366, 370 and

385; and is served by the Rock Island, the Colorado and Southern, and the Panhandle and Santa Fe railways. The population, which in 1890 was only 482, was 15,494 in 1920; and was 43,132 in 1930 by the Federal census. Its rapid growth is due to the development of the entire Texas "Panhandle," of which it is the commercial centre. The wholesale and jobbing business amounts to \$100,000,000 a year; the bank deposits aggregated \$25,000,000 in 1927; and the assessed valuation of property was \$39,000,000. There are large business buildings and the hotels have 3,000 guest rooms. The building permits issued in 1926 represented values of \$16,400,000. A water-supply system sufficient for a city of 100,000 has been undertaken. There are grain elevators, packing houses, creameries, a zinc smelter, an oil refinery and large railway shops. Amarillo was incorporated in 1887 and adopted a commission-manager form of government in 1913.

AMARNA TABLETS, a collection of clay tablets with cuneiform inscriptions, a poem, letters and other documents, discovered at El Amarna. These inscriptions have materially advanced our knowledge of the languages and legends of Babylonia and Assyria. (See *Cambridge Ancient History*, vol. i. 2nd ed. 1924.)

AMARYLLIDACEAE, the amaryllis family, a numerous group of monocotyledonous plants, closely allied to the lily family (Liliaceae). Familiar representatives are the daffodil, jonquil, snowdrop, snowflake and tuberose (*qq.v.*). The family comprises about 90 genera and 1,050 species, found chiefly in tropical and subtropical regions. Many are bulbous plants of arid lands, leafing only in spring or after rains. A large number bear handsome lily-like flowers, often popularly called lilies, as Amazon lily (*Eucharis grandiflora*), spider lily (*Hymenocallis* sp., *Pancratium*, sp.) and zephyr lily (*Zephyranthes* sp.). Among the larger genera are *Agave*, *Crinum*, *Hippeastrum*, *Hypoxis* and *Narcissus*. Various species of *Agave* yield valuable fibres, as henequen, pita and sisal hemp; the bulbs of some species are used in medicine, while those of the South African belladonna lily (*Amaryllis Belladonna*) and the buphane (*Buphane disticha*) are highly toxic, the latter furnishing a Kafir arrow-poison. Representatives of more than 40 genera are grown as ornamental plants in greenhouses and gardens. Native plants of the family in the British Isles are the yellow daffodil (*Narcissus Pseudo-Narcissus*), the snowdrop (*Galanthus nivalis*) and the summer snowflake (*Leucojum aestivale*). In North America there are more than 40 native species; these are found chiefly in the southern and the south-western United States and belong mostly to the genera *Agave*, *Hymenocallis* and *Zephyranthes*. Of those native to the eastern United States, the best known are the atamasco lily (*Zephyranthes Atamasco*), cultivated for its handsome flowers, and the yellow star-grass (*Hypoxis hirsuta*), the only representative extending northward into Canada. (See AGAVE; AMARYLLIS; HEMP; HIPPEASTRUM; LILIACEAE; NARCISSUS; SISAL HEMP.)

AMARYLLIS (the name of a girl in classical pastoral poetry), in botany, a genus of the family Amaryllidaceae, containing the belladonna lily (*Amaryllis Belladonna*), a native of South Africa, which was introduced into cultivation at the beginning of the 18th century. This is a half-hardy bulbous plant, producing in the spring a number of strap-shaped, dull green leaves, 1-1½ ft. long, arranged in two rows, and in autumn a solid stem, bearing at the top a cluster of 6-12 funnel-shaped flowers, of a rose colour and very fragrant. Several forms are known in cultivation. Most of the so-called Amaryllis of gardens belong to the allied genus *Hippeastrum* (*q.v.*).

AMASIA, the chief town of the Amasia vilayet of Asia Minor and an important trade centre on the Samsun-Sivas road, beautifully situated on the Yeshil Irmak (*Iris*). Pop. (1927), 60,527, including many Kizilbash (Shia). It was one of the chief towns of the kingdom of Trebizond and of the Seljuks, one of whose sultans, Kaikobad I., enriched it with fine buildings and restored the castle, which was thus enabled to stand a seven months' siege by Timur. It was also much favoured by the early Osmanli sultans, one of whom, Selim I., was born there. Bayezid II. built a fine mosque. Amasia is an unusually well-built Turkish

town with a good bazaar and khans and a fine clock-tower. It has extensive fruit gardens. Wheat, flour and silk are exported.

Ancient Amasia has left little trace of itself except on the castle rock, on the left of the river, where the acropolis walls and a number of splendid rock-cut tombs, described by Strabo as those of the kings of Pontus, can be seen. Amasia rose to historical importance after the time of Alexander as the cradle of the power of Pontus; but the last king to reign there was the father of Mithradates Eupator "The Great." The latter, however, made it the base of his operations against the Romans in 89, 72 and 67 B.C. Pompey made it a free city in 65, after Mithradates' fall. It was the birthplace of Strabo.

AMASIS or AMOSIS (the Greek forms of the Egyptian name *Ahmose*, *Ahmosi*, "the moon is born," often written *Aahmes* or *Ahmes* in modern works), the name of two kings of ancient Egypt.

Amasis I., the founder of the 17th dynasty, is famous for his successful wars against the Hyksos princes who still ruled in the north-east of the Delta (*see* EGYPT: *History*).

Amasis II. was the last great ruler of Egypt before the Persian conquest, 570–526 B.C. Most of our information about him is derived from Herodotus (ii. 161 *et seq.*) and can only be imperfectly controlled by monumental evidence. According to the Greek historian he was of mean origin. A revolt of the native soldiers gave him his opportunity. These troops, returning home from a disastrous expedition to Cyrene, suspected that they had been betrayed in order that Apries, the reigning king, might rule more absolutely by means of his mercenaries, and their friends in Egypt fully sympathized with them. Amasis, sent to meet them and quell the revolt, was proclaimed king by the rebels, and Apries, who had now to rely entirely on his mercenaries, was defeated and taken prisoner in the ensuing conflict at Momemphis; the usurper treated the captive prince with great lenity, but was eventually persuaded to give him up to the people, by whom he was strangled and buried in his ancestral tomb at Sais. An inscription confirms the fact of the struggle between the native and the foreign soldiery, and proves that Apries was killed and honourably buried in the third year of Amasis. Although Amasis thus appears first as champion of the disparaged native, he had the good sense to cultivate the friendship of the Greek world, and brought Egypt into closer touch with it than ever before. Herodotus relates that under his prudent administration Egypt reached the highest pitch of prosperity; he adorned the temples of Lower Egypt especially with splendid monolithic shrines and other monuments (his activity here is proved by remains still existing). Amasis confirmed the Greeks in possession of the commercial colony of Naucratis on the Canopic branch of the Nile, apparently with a definite charter, and when the temple of Delphi was burned he contributed 1,000 talents to the rebuilding. He also married a Greek princess named Ladice, the daughter of Battus, king of Cyrene, and he made alliances with Polycrates of Samos and Croesus of Lydia. His kingdom consisted probably of Egypt only, as far as the First Cataract, but to this he added Cyprus, and his influence was great in Cyrene. At the beginning of his long reign, before the death of Apries, he appears to have sustained an attack by Nebuchadrezzar (568 B.C.). Cyrus left Egypt unmolested; but the last years of Amasis were disturbed by the threatened invasion of Cambyses and by the rupture of the alliance with Polycrates of Samos. The blow fell upon his son Psammetichus III., whom the Persian deprived of his kingdom after a reign of only six months.

AMA SWAZI: *see* SWAZI.

AMA TEMBU: *see* TEMBU.

AMATEUR, a person who takes part in any art, craft, game or sport for the sake of the pleasure afforded by the occupation itself and not for pecuniary gain (Lat. *amator*, lover). Being thus a person for whom the pursuit in question is a recreation and not a business, and who therefore presumably devotes to it a portion only of his leisure and not his working hours, the average amateur

usually possesses less skill than the average professional, whose livelihood and reputation depend on his proficiency, and who therefore concentrates all his energies on the task of attaining the greatest possible mastery in his chosen career. In the arts, such as music, painting and the drama, the best amateurs are outdistanced as executants not merely by the best professionals but by professionals far below the highest rank; and although the inferiority of the amateur is not perhaps so pronounced or so universal in the case of games and outdoor sports, the records of such pastimes as boxing, billiards, motor-cycle racing and golf prove that here also the same contrast is to be found. Hence it has come about that the term "amateur" has acquired a secondary meaning, usually employed somewhat contemptuously, signifying inefficiency, unskilfulness, superficial knowledge or training.

The immense increase in popularity of athletic contests and games of all kinds in modern times, and especially the keen competition for "records" and championships, often of an international character, have made it a matter of importance to arrive at a clear and formal definition of the amateur as distinguished from the professional. The simple, straightforward definition of the amateur given above has been evaded. Cases are not unknown in the history of county cricket where players preserve their amateur status who, although they are not directly paid wages for cricket, are provided with the money enabling them to take a regular part in the sport by means of a salaried secretaryship or other office, very liberal grants for expenses, etc. Similarly "gentlemen riders" sometimes receive indirect remuneration. The various associations controlling the different branches of sport have therefore devised working regulations to be observed so far as their jurisdiction extends. Thus the Amateur Athletic Association of Great Britain defines an amateur as "one who has never competed for a money prize or staked bet, or with or against a professional for any prize, or who has never taught, pursued or assisted in the practice of athletic exercises as a means of obtaining a livelihood." The rules of the Amateur Rowing Association are stricter, denying amateur status to anyone who has ever steered or rowed in a race with a professional for any prize, or who is or has been by trade or employment for wages a mechanic, artisan or labourer, or engaged in any menial duty, besides insisting upon the usual restrictions in regard to taking money and competing with professionals. In association football the rules are much more lax, for although amateurs are clearly distinguished from professionals; an amateur may even become a regular member, though unsalaried, of a professional team without losing his amateur status. The Rugby game was, up to 1895, entirely controlled by the Rugby Football Union, which, by the strictness of its laws, effectually prevented the growth of professionalism, but there had been much dissatisfaction in the provinces with the Union's decision against reimbursing day-working players for "broken time," *i.e.*, for that part of their wages which they lost by playing on working days, and this resulted in the formation (1895) of the Northern Union, which permitted remuneration for "broken time" but allowed no person who worked for his living to play football unless regularly employed at his trade. Later the Northern Union became purely professional in character and developed into the Rugby league. In 1927 the International Olympic Committee was persuaded to announce that payment for "broken time" might in the case of Association football be made to the employer(s) of the player(s) affected. This announcement was completely contrary to the whole spirit of these modern games, as revived by Baron Pierre de Coubertin, and as defined in 1908 in legislation accepted by all the nations then competing. The British Football Association therefore withdrew from the Olympic Games (1928); and other developments of the same kind will probably occur. In the United States the amateur question has been less vexed than in Great Britain and is less complicated in theory, although the intensely businesslike character of the American conception of sport has encouraged professionalism. The Amateur Athletic Union of the United States recognizes all amateur sports and claims jurisdiction over certain important branches, excepting, however, baseball, football, golf, rowing and tennis (*see* ATHLETIC SPORTS, section, *United States*).

The A.A.U. rules on the amateur status define an amateur sportsman as "one who engages in sport solely for the pleasure and physical, mental or social benefits he derives therefrom, and to whom sport is nothing more than an avocation."

The rules, so far as they relate to professionalism, are: No person shall be eligible to compete in any athletic meeting, game or entertainment, given or sanctioned by this Union, who has (1) received or competed for compensation or reward in any form for the display, exercise or example of his skill or knowledge of any athletic exercise, or for rendering personal service of any kind to any athletic organization, or for becoming or continuing a member of any athletic organization; or (2) has entered any competition under a name other than his own, or from a club of which he was not at that time a member in good standing; or (3) has knowingly entered any competition open to any professional or professionals, or has knowingly competed with any professional for any prize or token; or (4) has issued or allowed to be issued in his behalf any challenge to compete against any professional or for money; or (5) has pawned, bartered or sold any prize won in athletic competition. It will be seen that by rule 3 the American Union enacts a standard for all athletes not much different from that of the British Amateur Rowing Association. The rules for the sports not within the Union's jurisdiction are practically the same, except that in baseball, cricket and golf, amateurs may compete with professionals, though not for cash prizes. The number of professional football players has grown in recent years and many of the more widely known recruits have come from college football. Not a few of the greatest of the professional baseball players have played the game at college. The question whether a college undergraduate may legally play baseball for pay during the summer months has not yet been definitely answered. The Rugby Football Union recognizes no such person as a professional player.

It is probably impossible to produce any definition of an amateur which will cover all sports in any single nation. It is hopeless to try to define an amateur for all sports all over the world. The only reasonable method of getting amateurs together in any great international meeting is to lay the responsibility for their selection and appearance upon the governing body of the sport in which they compete in the nation which they represent. These governing bodies at least will have fairly similar rules in all countries, because, in nearly every case, they are affiliated to international associations of the particular sport concerned; and therefore practical justice will be as nearly as possible satisfied. (See also *ATHLETIC SPORTS, United States*, and *Savage, Games and Sports in British Schools and Universities*, ch. vii., 1927.)

AMA THONGA: see THONGA.

AMATHUS, ancient city, Cyprus, on the south coast, about 24m. W. of Larnaka and 6m. E. of Limassol, among sandy hills and sand-dunes, which perhaps explains its name (Greek *ἀμᾶθος*, sand). The earliest remains hitherto found on the site are of the early iron age (1000–600 B.C.). Amathus maintained strong Phoenician sympathies, and refused to join the revolt of Cyprus against Persia (500–494 B.C.) (Herod. v. 105). Evagoras of Salamis was similarly opposed by Amathus about 385–380 B.C. in conjunction with Citium and Soli (Diod. Sic. xiv. 98); and even after Alexander the city resisted annexation (Diod. Sic. xix. 62). Its temple of Adonis and Aphrodite (*Venus Amathusia*) remained famous in Roman time but is quite destroyed. Amathus derived its wealth from corn and from copper mines, of which traces can be seen inland; Ovid also mentions its sheep (*Met.* x. 227). But the epithet *Amathusia* in Roman poetry often means little more than "Cypriote." Amathus still flourished and produced a patriarch of Alexandria (Johannes Eleemon), as late as 606–616, but it was almost deserted when Richard Coeur de Lion won Cyprus by a victory there over Isaac Comnenus in 1191. The rich necropolis has yielded valuable works of art; but the city has vanished, except fragments of a Byzantine church, and a great stone bowl on the acropolis. A similar vessel was transported to the Louvre in 1867. (See also *CYPRUS*.)

tions in Cyprus (1899); E. Oberhummer in *Pauly-Wissowa* (s.v.).

AMATI, the name of a family of Italian violin makers, who flourished at Cremona from about 1550 to 1692. According to Fétis, Andrea and Nicolo Amati, two brothers, were the first Italians who made violins. They were succeeded by Antonio and Geronimo, sons of Nicolo. Another Nicolo, son of Geronimo, was born on Sept. 3, 1596, and died on Aug. 12, 1684. He was the most eminent of the family. He improved the model adopted by the rest of the Amati and produced instruments capable of yielding greater power of tone. His pattern was usually small, but he also made the so-called "Grand Amatis." Of his pupils the most famous were Andrea Enamieri and Antonio Stradivari.

AMATITLÁN or **SAN JUAN DE AMATITLÁN**, the capital of a department bearing the same name in Guatemala, on Lake Amatitlán, 15m. S.W. of Guatemala city by the trans-continental railway from Puerto Barrios to San José. The population in 1921 was 37,705. The town consists almost entirely of one-storeyed adobe huts inhabited by mulattos and Indians, whose chief industry is the production of cochineal. In 1840 only a small Indian village marked its site, and its subsequent growth was due to the sugar plantations established by a Jesuit settlement. The wells of the town are strongly impregnated with salt and alum, and in the vicinity there are several hot springs. Lake Amatitlán, 9m. long and 3m. broad, lies on the northern side of the great Guatemalan Cordillera. Above it rises the four-cratered volcano of Pacaya (8,390 ft.), which was in eruption in 1870. The outlet of the lake is a swift river 65m. long, which cuts a way through the Cordillera, and enters the Pacific at Istapa, after forming at San Pedro a fine waterfall more than 200ft. high.

AMAUIROSIS, a term for "deprivation of sight," limited chiefly to those forms of defect or loss of vision which are caused by diseases not directly involving the eye.

AMAURY: see AMALRIC OF BENA.

AMA XOSA: see XOSA.

AMAZON, the great river of South America and the largest in the world in volume although exceeded in length by the Mississippi-Missouri. In the year 1500, Vicente Yañez Pinzon, in command of a Spanish expedition, discovered and ascended the Amazon to a point about 50 m. from the sea. He called it the *Rio Santa Maria de la Mar Dulce*, which soon became abbreviated to *Mar Dulce*. For some years after 1502 it was known as the *Rio Grande*. The companions of Pinzon, in giving evidence in 1515, mention it as *El Ryo Marañón*.

The first descent of the river from the Andes to the sea was made in 1541 by Orellana who reached the main stream by way of the Napo River. It is rather generally accepted that the name *Amazonas* was given to the river by Orellana after a battle with the Tapuyas savages in which he believed that the women of the tribe fought with the men. The first ascent of the river was made in 1638 by Pedro Texiera, a Portuguese, who reversed the route of Orellana and reached Quito by way of the Mapo.

The Amazon River has a drainage area of 2,722,000 sq.m. if the Tocantins is included. It drains four-tenths of South America and gathers its waters from 5° N. to 20° S. latitude. The main stream rises in a chain of glacier-fed lakes on the eastern border of the main range of the Andes in Central Peru, about 1,000 m. N.N.E. of Lima, and flows for 4,000 m. across Peru and Brazil to enter the Atlantic on the equator. While Amazon, or *Amazonas*, is popularly applied to the whole of the main stream it is properly applied only to sections of it in Peruvian and Brazilian nomenclature. In Peru the upper stream from its source to Iquitos is called Marañón and, from there to the sea, Amazonas. In Brazil the name Solimões is used from Iquitos to the mouth of the Negro River and Amazonas only from the Negro River to the sea. Beginning with the lower river the great tributaries to the main stream will be discussed in order, beginning with the southern or larger affluents.

TRIBUTARIES

The TOCANTINS is not really a branch of the Amazon. It is the central fluvial artery of Brazil, running from south to north for

a distance of about 1,500 miles. It rises in the mountainous district of Pyrenopolis, but its more ambitious western affluent, the Araguay, has its extreme southern headwaters on the slopes of the Sierra Cayapó, and flows 1,080m. before its junction with the parent stream, which it appears almost to equal in volume. Besides its main tributary, the Rio das Mortes, it has 20 smaller branches, offering many miles of canoe navigation. The Pará river, generally called one of the mouths of the Amazon, is only the lower reach of the Tocantins.

The XINGÚ, the next large river west of the Tocantins, was first explored by Karl von den Steinen in 1884-87. The river is formed at about 12° S. lat., by the union of three large headwater streams, the Ronuro, the Tamitotoala, and the Kuluene, all of which, together with their more important tributaries, rise in an area only about 80m. long from west to east and some 200m. N.E. of Cuyabá. From a point about 75m. from the union of these streams the Xingú enters a 400-mile stretch of rapids that are serious obstacles even to canoe navigation.

The TAPAJOS, running through a humid, hot and unhealthy valley, pours into the Amazon 500m. above Pará and is about 1,200m. long. It rises on the lofty Brazilian plateau near Diamantino in 14° 25' S. lat. Near this place a number of streams unite to form the river Arinos. The Arinos, the Alto Tapajos and the Tapajos to the last rapid, the Maranhão Grande, is a continuous series of formidable cataracts and rapids; but from the Maranhão Grande to its mouth, about 188m., the river can be navigated by large vessels.

The MADEIRA has its junction with the Amazon 870m. by river above Pará, and almost rivals it in the volume of its waters. It rises more than 50ft. during the rainy season, and the largest ocean steamers may ascend it to the Fall of San Antonio, 663m. above its mouth; but in the dry months, from June to November, it is only navigable for the same distance for craft drawing from 5 to 6ft. of water. According to the Treaty of San Ildefonso, the Madeira begins at the confluence of the Guaporé with the Mamoré. The Guaporé has its headwaters almost in contact with those of the Paraguay River, but the idea of a connecting canal is based on ignorance of local conditions. San Antonio is the first of a formidable series of cataracts and rapids, 19 in number, which, for a river distance of 263m., obstruct the upper course of the Madeira until the last rapid, called Guajará Mirim (small pebble), is reached, about 120m. below the union of the Guaporé with the Mamoré. The Beni River joins the Madeira at the Madeira Rapids, a stretch of nearly 5 miles of reefs, whirlpools and rapids, about 40m. below the Guajará Mirim Rapids. From the Guaporé, Mamoré and Beni rivers the Madeira receives the drainage from the whole of the eastern and north-eastern slopes of the Andes from the southernmost sources of the Rio Grande (a tributary of the Mamoré) at about 20° S. lat. to the northernmost sources of the Madre de Dios River (a tributary of the Beni) at about 12° S. lat., the whole of the south-western slope of the Brazilian Matto Grosso, and the northern slope of the Sierra de Chiquitos in the Gran Chaco. All of the upper branches of the Madeira flow across open, almost level plains, which, although some 35,000 sq.m. of them are yearly flooded to an average depth of 3ft. for a period of from three to four months, form an agricultural and grazing region that is probably the most healthful and most inviting of the whole Amazon Basin.

The PURÚS, a very sluggish river, enters the Amazon about 230m. west of the Madeira, which it parallels as far as the falls of the latter stream. It is practically only a drainage ditch for the half-submerged, lake-flooded district it traverses. Chandless found its elevation above sea-level to be only 107ft. 590 miles from its mouth. It is due to this extremely gentle gradient that the river, although a young stream, exhibits the meandering character of a mature stream. It is one of the most crooked rivers in the world, its length in a straight line being less than half that by its meanders. One of its marked characteristics is the five parallel *furos*, side channels to the main stream, by which its lower course is connected with the Amazon; the largest and most westerly one connecting with the Purús about 150m. above its mouth. Its width is very uniform for 1,000m. up, and for

800m. its depth is never less than 45 feet. It is navigable by steamers for 1,648m. as far as the little stream, the Curumahá, but only by light-draught craft. Chandless ascended it 1,866 miles. At 1,792m. it forks into two small streams.

The JURUÁ is the next great southern affluent of the Amazon west of the Purús and traverses the same sort of low, half-flooded country as the latter. It has the same character as the Purús as regards gentleness of gradient, meanders and sluggishness. It rises in the highlands east of the Ucayali which carry the Peru-Brazil boundary and is navigable for a distance of 1,133 m. above its junction with the Amazon.

The JAVARY, the boundary line between Brazil and Peru, is another Amazon tributary of importance. It is navigable by canoe for 900m. above its mouth to its sources among the Ucayali highlands, but only 260m. have been found suitable for steam navigation. The Brazilian Boundary Commission ascended it in 1866 to the junction of the Shino with its Jaquirana branch. The country it traverses in its extremely sinuous course is very level, similar in character to that of the Juruá.

The UCAYALI is second only in size to the Madeira among the tributaries of the Amazon. Its headwaters drain a great section of the Peruvian plateau from the source of the Vilcanota River only 70 m. N.W. of Lake Titicaca to the sources of the Mantaro west of Cerro de Pasco. The lower 500 m. of the main channel is bordered by large islands formed by numerous side-channels; the whole being very low and flooded in the rainy season. The Ucayali is navigable for light draft launches as far as the Tambourubamba junction but the main Lima-Iquitos route follows the Pichis-Pachitea tributary.

The HUALLAGA which joins the Marañón about midway between the Pongo de Manseriche and the mouth of the Ucayali has its true source in the Yanahuanca River, a stream flowing from a series of glacier-fed lakes which lie north-west of the famous mining centre of Cerro de Pasco on the eastern slope of the main range of the Andes between the sources of the Marañón and Mantaro rivers. The name Huallaga is applied, however, to a more easterly and much less important headwater tributary which rises a short distance east of Cerro de Pasco. The whole stream is deeply entrenched and from the town of Huánuco to the mouth of the river much of its course is impeded by rapids and gorges. Between the Huallaga and the Ucayali lie the famous Pampas de Sacramento, vast plains broken by low outliers of the Andes, forested in part, but said to consist largely of grass-covered areas suited to cattle raising.

The MARAÑÓN River rises in Lake Lauricocha, the northernmost of a chain of glacier-fed lakes about 100 m. N.N.E. of Lima and flows northward in a deeply eroded valley. It is due to this and other deeply entrenched longitudinal valleys that the tributaries of the Amazon have cut in the Peruvian plateau that the erroneous conception of the Peruvian Andes as three separate mountain ranges has arisen. At about 5° 30' S. lat. the river makes a great bend toward the north-east and, after passing through a succession of narrows or *pongos* and no less than 35 formidable rapids, it breaks through from the Peruvian plateau to the Amazon Plain by a great canyon known as the Pongo de Manseriche. This canyon is about 2,000ft. deep and narrows in places to a width of only 100ft. Through this dark canyon the Marañón flows, at times, at a rate of over 12m. an hour. Beyond the *pongo* the river receives several large tributaries from the north and spreads out into a broad stream with numerous channels and islands.

From the north the Amazon receives many tributaries, but their total volume of water is not nearly so great as that contributed to the parent stream by its affluents from the south. The part of Brazil lying between the Amazon and French, Dutch and British Guiana, and bounded on the west by the Rio Negro, is known as Brazilian Guiana. It is the southern slope, very convolved, of the northern section of the Brazilian Archaean block. Their northern slope, which is occupied by the three Guianas first named, is saturated and river-torn; but their southern one, Brazilian Guiana, is in general thirsty and semi-barren, and the driest region of the Amazon valley. It is an area which has been left almost in the

undisturbed possession of nomadic Indian tribes.

The **TROMBETAS** is the first river of importance we meet on the northern side as we ascend the Amazon. Its confluence with this is just above the town of Obidos. It has its sources in the Guiana highlands, but its long course is frequently interrupted by violent currents, rocky barriers and rapids. The river is navigable for 135m. above its mouth.

The **NEGRO**, the great northern tributary of the Amazon, has its sources along the watershed between the Orinoco and the Amazon basins, and also connects with the Orinoco by way of the Casiquiare Canal. The Negro is navigable in dry season for 450 m. above its mouth for vessels of 4 ft. draft, but it has many sandbanks and minor obstructions. In the wet season it overflows its banks, in places to a width of 20 miles. Its lower course is very wide and full of long islands and intricate channels. The main headwater affluent of the Negro is the Uaupes. Its principal affluent from the north is the Branco formed by the union of the Uraricuera and Takatú which, with their tributaries drain a large section of the southerly slopes of the Guiana Highlands which separate Brazil from Venezuela and British Guiana. The Branco flows nearly straight south for 350 miles to the Negro which it enters by numerous channels similar to those of the lower course of the latter.

The Casiquiare Canal which connects the upper Orinoco, about 18 m. below the old mission site of Esmeraldas, with the Rio Negro affluent of the Amazon near the village of San Carlos, is a natural waterway, the only one of its kind known in the world. The existence of the canal was first reported by Father Acuña in 1639 but was not confirmed until 1744, when the Jesuit Father Roman, ascending the Orinoco, met Portuguese slave-traders from settlements on the Rio Negro, accompanied them on their return by way of the Casiquiare Canal and returned to the Orinoco by the same route. According to data obtained by the Rice Expedition which made a survey of the canal in 1919, the length of the canal is 227 m. Its width at its beginning in the Orinoco is 758 ft.; but this rapidly narrows down to 150 ft. and widens again to 2,150 ft. at its mouth in the Negro. The level of the water at the Orinoco end was found to be 283 ft. and, at the Rio Negro end, 212 ft. giving the canal an average slope toward the Negro of 7.2 in. per mile. The banks of the canal are heavily forested. The chief inhabitants of the region are Indians of the Maquiratares tribe although there are some whites engaged in rubber gathering. There are several small settlements at the lower end of the canal of which Solano was founded while the Scientific Expedition of the Boundary Commission of 1756 was at work in the region.

The **YAPURÁ**. West of the Negro the Amazon receives three imposing streams from the north-west—the Yapurá, the Iça or Putumayo and the Napo. The first was formerly known as the Hyapora, but its Brazilian part is now called the Yapurá, and its Colombian portion the Caquetá. Barão de Marajo gives it 600m. of navigable stretches. Jules Crevaux, who descended it, describes it as full of obstacles to navigation, the current very strong and the stream frequently interrupted by rapids and cataracts. It rises in the Colombian Andes, nearly in touch with the sources of the Magdalena, and augments its volume from many branches as it courses through Colombia.

The **IÇA** or **PUTUMAYO**, west of and parallel to the Yapurá, was found much more easily navigated by Crevaux. He ascended it in a steamer drawing 6ft. of water, and running day and night. He reached Cuemby, 800m. above its mouth, without finding a single rapid. Cuemby is only 200m. from the Pacific ocean, in a straight line.

The **NAPO** rises among the volcanoes of the eastern border of the Andes in northern Ecuador. Its headwater tributaries in the Ecuadorian Oriente flow through one of the least known areas of the eastern border of the Andes. The course of only its southernmost headwater tributary, the Anzu, is definitely known. The Coca which is believed to have its source on the slopes of Cayambe Volcano close to the equator, and the Aguarico, an important river with headwaters between Cayambe and the Colombian frontier, join it from the north. The Curaray, a tributary of secondary

importance, joins it from the south some 200 miles from its mouth. The Napo is navigable for river craft to this point and by canoes to the mouth of the Coca. The Curaray-Coca section of the river is little-known.

The **NANAY** is the next Amazon tributary of importance west of the Napo. It belongs entirely to the lowlands, and is very crooked, has a slow current and divides much into *caños* and

BY COURTESY OF THE AMAZON EXPEDITION OF THE MUSEUM OF U. OF PA.

WAPISIANA WOMEN OF THE AMAZON BASIN IN SOUTHERN BRITISH GUIANA ENGAGED IN HAMMOCK WEAVING

strings of lagoons which flood the flat, low areas of country on either side.

The **TIGRE** is the next west of the Nanay, and is navigable for 125m. from its confluence with the Amazon. Like the Nanay, it belongs wholly to the plains. Its mouth is 42m. west of the junction of the Ucayali with the Amazon.

The **PASTAZA** (the ancient River Sumatara) is the next large river we meet. It rises on the Ecuadorian tableland, where a branch from the valley of Riobamba unites with one from the Latacunga basin.

The **MORONA** flows parallel to the Pastaza and immediately to the west of it, and is the last stream of any importance on the northern side of the Amazon before reaching the Pongo de Manseriche. Above the Pongo de Manseriche two important tributaries, the Santiago and the Chinchipe join the Marañón from the north.

THE MAIN RIVER

Physical Characteristics.—The **AMAZON MAIN RIVER** is navigable for ocean steamers as far as Iquitos, 2,300m. from the sea, and 486m. higher up for vessels drawing 14ft. of water, as far as Achaual Point. Beyond that, according to Tucker, confirmed by Wertheman, it is unsafe; but small steamers frequently ascend to the Pongo de Manseriche, just above Achaual Point. The average current of the Amazon is about 3m. an hour; but, especially in flood, it dashes through some of its contracted channels at 5m. an hour. The U.S. steamer "Wilmington" ascended it to Iquitos in 1899. Commander Todd reports that the average depth of the river in the height of the rainy season is 120 feet. It commences to rise in November, and increases in volume until June, and then falls until the end of October. The rise of the Negro branch is not synchronous; for the steady rains do not commence in its valley until February or March. By June it is full, and then it begins to fall with the Amazon. The Amazon at times broadens to 4 and 6 miles. Occasionally, for long distances, it divides into two main streams, with inland, lateral channels, all connected by a complicated system of natural canals, cutting the low, flat *igapo* (recent alluvial) lands, which are never more than 15ft. above low river, into almost numberless islands. At the narrows of Obidos, 400m. from the sea, it is compressed into a single bed a mile wide and over 200ft. deep, through which the water flows at the rate of 4 to 5m. an hour. In the rainy season it inundates the country throughout its course to the extent of several hundred thousand square miles, covering

PLANT AND ANIMAL LIFE IN THE BASIN OF THE AMAZON RIVER

1. Typical jungle scenery on the upper Amazon, showing trunks of the palm trees in the foreground covered with a creeping parasitic plant that is very destructive to them
2. Native beaters in the upper region of the Amazon risking their lives in an attempt to round up crocodiles by driving them out of the swamp and up the river
3. Round-up of thousands of crocodiles as a result of efforts of the beaters for several days (see fig. 2). Over 2,000 reptiles were killed
4. Native hut which German explorers used as a station when stopping on expedition into the upper Amazon in 1924 and 1925

the flood-plain, called *vargem* (land between the levels of moderate and high floods). The flood-levels are in places from 40 to 50 ft. high above low river. Taking four roughly equidistant places, the rise at Iquitos is 20 ft., at Tefé 45, near Obidos 35, and at Pará 12.

The first high land met in ascending the river is on the north bank, opposite the mouth of the Xingú, and extends for about 150 m. up, as far as Monte Alegre. It is a series of steep, table-topped hills, cut down to a kind of terrace which lies between them and the river. Monte Alegre reaches an altitude of several hundred feet. On the south side, above the Xingú, a line of low bluffs extends in a series of gentle curves with hardly any breaks nearly to Santarem, but a considerable distance inland, bordering the flood-plain, which is many miles wide. Then they bend to the south-west, and, abutting upon the lower Tapajos, merge into the bluffs which form the terrace margin of that river valley. The next high land on the north side is Obidos, a bluff, 56 ft. above the river, backed by low hills. From Serpa, nearly opposite the river Madeira, to near the mouth of the Rio Negro, the banks are low, until approaching Manáos, they are rolling hills; but from the Negro, for 600 m., as far up as the village of Canaria, at the great bend of the Amazon, only very low land is found, resembling that at the mouth of the river.

On the south side, from the Tapajos to the river Madeira, the banks are usually low, although two or three hills break the general monotony. From the latter river, however, to the Ucayali, a distance of nearly 1,500 m., the forested banks are just out of water, and are inundated long before the river attains its maximum flood-line. Thence to the Huallaga the elevation of the land is somewhat greater; but not until this river is passed, and the Pongo de Manseriche approached, does the swelling ground of the Andean foot-hills raise the country above flood-level.

The Amazon is not a continuous incline, but probably consists of long, level stretches connected by short inclined planes of extremely little fall, sufficient, however, owing to its great depth, to give the gigantic volume of water a continuous impulse towards the ocean. The lower Amazon presents every evidence of having once been an ocean gulf, the upper waters of which washed the cliffs near Obidos. Only about 10% of the water discharged by the mighty stream enters it below Obidos, very little of which is from the northern slope of the valley. The drainage area of the Amazon basin above Obidos is about 1,945,000 sq. m., and, below, only about 423,000 sq. m., or say 20%, exclusive of the 354,000 sq. m. of the Tocantins basin.

The width of the mouth of the river is usually measured from Cabo do Norte to Punto Patijoca, a distance of 207 statute m.; but this includes the ocean outlet, 40 m. wide, of the Pará river, which should be deducted, as this stream is only the lower reach of the Tocantins. It also includes the ocean frontage of Marajo, an island about the size of the kingdom of Denmark lying in the mouth of the Amazon. Following the coast, a little to the north of Cabo do Norte, and for 100 m. along its Guiana margin up the Amazon, is a belt of half-submerged islands and shallow sandbanks. Here the tidal phenomenon called the *bore*, or Pororoca, occurs, where the soundings are not over 4 fathoms. It commences with a roar, constantly increasing, and advances at the rate of from 10 to 15 m. an hour, with a breaking wall of water from 5 to 12 ft. high. Under such conditions of warfare between the ocean and the river, it is not surprising that the ocean is rapidly eating away the coast and that the vast volume of silt carried by the Amazon finds it impossible to build up a delta.

The Amazon is not so much a river as it is a gigantic reservoir, extending from the sea to the base of the Andes, and, in the wet season, varying in width from 5 to 400 miles.

Population, Trade, etc.—On Sept. 6, 1850, the emperor, Dom Pedro II., sanctioned a law authorizing steam navigation on the Amazon, and confided to an illustrious Brazilian, Barão Mauá (Irineu Evangelista de Sousa), the task of carrying it into effect. He organized the "Companhia de Navegação e Commercio do Amazonas" at Rio de Janeiro in 1852; and in the following year it commenced operations with three small steamers, the "Monarch," the "Tarajo" and "Rio Negro." At first the navigation was principally

confined to the main river; and even in 1857 a modification of the Government contract only obliged the company to a monthly service between Pará and Manáos, with steamers of 200 tons cargo capacity, a second line to make six round voyages a year between Manáos and Tabatinga, and a third, two trips a month between Pará and Cametá. The Government paid the company a subvention of £3,935 monthly. Thus the first impulse of modern progress was given to the dormant valley. The success of the venture called attention to the unoccupied field; a second company soon opened commerce on the Madeira, Purús and Negro; a third established a line between Pará and Manáos; and a fourth navigated some of the smaller streams; while the Amazonas Company had largely increased its fine fleet.

The economic vicissitudes through which the Amazon basin has passed in late years are traceable largely to changes in the rubber industry. Although crude rubber was sent from the Amazon as early as 1827, several decades passed before the annual exportation attained commercial importance. With the remarkable increase in the demand for rubber, prices rose, and gatherers in the forests were sent further afield.

About 1910–11 prices reached their highest point, yearly exportations amounted to thousands of tons and numerous river craft plied on the Amazon and its tributaries. The inhabitants of the valley were almost exclusively engaged in rubber exploitation. The growing of foods was largely abandoned, even necessary commodities being imported. About this period, however, plantation rubber trees of the East Indies were coming into bearing and the result was a collapse by 1915 of the one great industry of the region. During the five years ending in 1927 there was a gradual increase of rubber exportation from the Amazon region, the total shipments for 1927 being in excess of 28,700 long tons.

A land concession of 3,700,000 ac. granted by Brazil in 1927 to the Ford Motor Company, Detroit, Mich., and the formation of a Brazilian subsidiary with Brazilian stockholders provide large capital for the development of plantation rubber. The land lies along the eastern side of the Tapajos river 125 to 150 m. south of Santarem on the Amazon. The two rivers afford sufficient water depth for ocean-going vessels to traffic directly with the plantations, work upon which is progressing.

Trading Spheres.—Exporters and importers recognize three trading spheres: the regions, respectively, of Pará (or Belém), Manáos and Iquitos. Numerous European and American steamships call at Pará; some proceed to Manáos, while others go up the river to Iquitos. Motor-cars are numerous in Pará and Manáos, and are being introduced into regions such as Cobiya in Bolivia and other primitive settlements. Electric-light plants are in operation in larger cities and in Obidos, Porto Velho, Riberalta, Cobiya, Amenquer, etc. River steamers are also thus equipped. The Mamoré-Madeira railroad, 220 m. around Madeira Falls, opened in 1912, provides access to additional virgin territory. Land telegraph and radio services operate between the several cities of the region and many smaller places, thereby lessening their isolation.

Estimates place the population of the Amazon basin at about 1,500,000, all but 200,000 being credited to Brazil. The city of Pará had 363,466 in 1920; Manáos, 75,704; Iquitos, 8,000; Santarem, 5,000; Obidos, 26,812. It is estimated that in the Amazon basin about 30,000 labourers might be recruited for agricultural or other purposes. Quantities of rubber, Brazil-nuts, fish and other products were being exported in 1925. The region's imports were also on the increase.

Expeditions.—During the period 1910–27 there were numerous expeditions, exploratory and scientific, into regions watered by the Amazon and its tributaries. Roosevelt and Rondon in 1913–14 in a notable trip down the so-called River of Doubt in two months covered 470 miles of this river, hitherto unknown except to rubber-gatherers and found it to be a branch of the Madeira, joining it at 5° 21' S. lat. The Fleming expedition (1919) studied the industrial possibilities of the region and Rice in a series of expeditions (1910 to 1924) made accurate surveys of the Negro, Uaupes and Branco. A Carnegie Museum expedition made a study of fishes; the Ellsworth, Farabee, Fawcett and other parties obtained geographic, geological and ethnographical

data. In 1923-24 the American Rubber Mission financed by the U.S. Government conducted a survey along a total of 37 waterways including the Tocantins, Xingú, Tapajós, Madeira, Mamoré, Beni, Madre de Dios, Acre, Purús, Ucayali, Huallaga, Negro and Branco. Special parties penetrated inland and examined soils and agricultural possibilities particularly with a view to the cultivation of rubber and sugar cane. Its leader, Dr. W. L. Schurz, was assisted by specialists from the U.S. Departments of Commerce and Agriculture (among them Dr. C. F. Marbut of the Bureau of Soils) and from the business world, and by experts from Brazil, Bolivia and Peru. In 1927 and 1928 the American Geographical Society, in connection with its work of collecting source material for the new map of Hispanic America on the millionth scale which the Society is producing from original sources, sponsored two expeditions to the Amazon Basin. Joseph H. Sinclair, the leader of one of these parties continued his surveys of the sources of the Napo River begun in 1921 and located a new volcano. The other, conducted by O. M. Miller, of the Society's School of Surveying, made reconnaissance surveys in Central Peru, including a topographic survey of the sources of the Marañón.

Early in 1925 Col. P. W. Fawcett, British explorer, with a small party left Cuyabá to explore the Xingú-Tapajós region of Brazil. After some months news ceased to come from the party and it was feared that they were lost. In 1928 Commander G. M. Dyott, of England, sailed from New York with a relief party, retraced Fawcett's route for some distance and reported that he had found evidence that the party had been killed by Indians. (X.)

Williamson, *English Colonies in Guiana and on the Amazon, 1604-1668* (1923); G. MacCreagh, *White Waters and Black* (1926); W. M. McGovern, *Jungle Paths and Inca Ruins* (1927).

Flora.—In diversity of forms and profusion of individuals the plant life of the Amazon river basin is probably the richest on the globe. Within the area drained by this river system, species of practically every oecological type find homes. Here most of the idiosyncrasies of the plant kingdom are in evidence, for this enormous territory presents a myriad-faced environment, and each face has its own peculiar complement of plant inhabitants. There are few parts of the earth's surface where the struggle for existence appears so intense, for plants literally swarm here.

Nearly all types of plant associations occur and many of these have native names, such as *monte*, *montaña* (forest), *varzea* (overflow forest), *curiche* (swampy meadow), *campo*, *pampa* (prairie or park-like country), *anunga* (araceous swamps, mostly of the arborescent relative of the calla-lily, *Montrichardia arborescens*), *terra firma* (in Brazil, land rarely, if ever, overflowed), *ceja* (bush, copse or chaparral), *pajonales* (small grass lands), *paramos* and *paramillos* (large and small alpine meadows).

The dominant feature of this area is the great forest—an expanse of green-topped columns that stretch from a 200m. front on the Atlantic in an ever-widening angle, almost across the continent to the snow-capped Andes. It ranges from the swampy tidewater mangrove thickets at sea-level to the bush country that marks the tree limit on the Andes at from 10,000 to 12,000ft. altitude, where the last arborescent remnants hug the stream borders.

The most striking characteristics of these vast woods are the comparative absence of pure stands of any tree species; the paucity of forest giants in large groups; the division of the vertical height of the forest into storeys or floors on account of the mass effects of the various growths as regards size; the multitudes of very different types, both as to form and habit, jumbled together, often in the most tangled confusion; the general absence of seasonal leaf-fall and flowering time; the small percentage of soft woods; the number of tree forms with prop-roots or buttressed trunks; the long distance between the forest floor and the first branches; the absence of great masses of floral colour and, comparatively speaking, the light colour of the bark.

In the temperate zones, solid forests of one or a few species are characteristic, so that they are designated under the name of their dominant species, such as oak or pine forests. On an acre of

Amazon forest, in most regions, scores of species occur, but only a few individuals of each, although there are considerable areas that might be called laurel forests.

Palms, myrtles, laurels, acacias, bignonias, cedrelas, cecropias, rosewoods, bombacaceas, Brazil-nuts, rubber trees, figs, purple-hearts and dozens of others often grow on one small area. Within a half-mile square, Agassiz counted 117 different woods. In some regions, particularly rain forest on certain mountain slopes, tree-ferns add to the variety. Conifers are practically absent.

In general, forest giants stand alone and are conspicuous against the sky-line because they number so few. They rarely exceed 200ft. and probably the average tree height of the larger growing species is not over 100 feet. Examples of species that attain the greatest height are the Brazilian cow-tree or *massaranduba* (*Mimosa elata*), the silk-cotton (*kapok*) or *samaúma* (*Eriodendron* sp.), *pau d'arco* (*Tecoma* sp.), *bacori* (*Symphonia* sp.), Brazil-nut or *castanhêira* (*Bertholletia* sp.), and the cream-nut or *sapucaia* (*Lecythis ollaria*). Species of fig and garlic trees (*Gallesia*) also reach huge proportions. As one stands in the midst of a typical section of the Amazonian wilderness, nothing is perhaps more impressive or full of greater contrast than the changing scenes presented as one glances from the forest floor to its blue-aperatured, sky-faced ceiling.

Often the floor level is covered by a mosaic of carpet forms (selaginellas, acantheas, thalias, ferns and bromeliads), beautiful both in design and colour. Beneath the willow-like *Tessaria* thickets on the sandy river flats meibomias form extensive mats. Gorgeous-hued amaryllids flower in clumps here and there. Our greenhouse lantana is a colourful fragrant weed. Sprays of various orchids cling to sticks, logs and small twigs. Several diminutive species remind one of tiny yellow, brown-splotted pansy sprays made up with equally delicately dimensioned iris leaves. Begonias, various in foliage and flower colour, are common. Profusions of fallen flowers in brilliant vivid shades of red, orange, yellow and pink frequently cover many square yards. Flowering trunks of the wild chocolate, huge buttresses of various forest giants, prop roots of certain palms and many vines and shrubs carry the eye upward to where they branch and leaf.

The second level is where the bushes, tall herbs and slender walking-stick palms flower, leaf and reach their maximum height. Red and yellow heliconias with their enormous banana-like leaves produce luxuriant tropical effects. Slender palms, with orange yellow panicles of male flowers, scent the glades. If fortune favours the visitor, the more open areas may be floriferous with the fugitive plum-like bloom of hirtellas and eugenias, or with the clambering types of pink and yellow orchids, sometimes with sprays 5ft. long. Along the river fronts in the higher altitudes (2,000 to 3,000ft.), calliandras with their profusion of brilliant henna-red cockades leave an unforgettable impression. Other typical plants of this level in some regions are the panama-hat plant (*toquilla*), the ivory-nut-palm (*tagua*), various passion-flowers and bignoniad vines, papayas and cassavas.

Still further the eye ascends to meet the crowns of the various shade-loving trees that form the third storey of the Amazonian forest. These include numerous species of palms (*Mauritia*, *Euterpe*, *Attalea*, *Guilielma*, *Iriarteia*), the chocolate-tree, the ant-protected tree member of the buckwheat family, *Triplaris*, or *palo de santo*, besides hordes of perching orchids, pipers, ferns, cacti, tradescantias, bromeliads and aroids. Finally there is the canopy that fronts the sky, where the sun-loving vines, perchers and larger trees flower and fruit.

Although the valley lies wholly within the tropics, on account of the range in altitude, temperate as well as tropical plants occur, and every marked change in elevation results in a consequent change in the characteristic species. The greatest differentiation in plant life between the various areas is found, generally speaking, on the outer edge or rim of the basin, where the streams start and the mountain spurs are barriers to the mixing of floras. Hence each mountain valley may have a distinctive flora, and the greater the distance from the delta, in general, the more varied the vegetation over large areas. In some of the peripheral Andean regions, the ascent is so rapid that within a few miles tropical, subtropical

and temperate climates are experienced. Bananas, coffee and oranges are grown on the valley floor, while toward the top of the mountain, the climate makes potatoes and barley successful crops. Tropical and temperate types under such conditions are present in strange companionships, such as the trail-side alder (*Alnus*) loaded with bright-flowered, perching bromeliads, cousins of the pineapple.

The region of the Amazon basin richest in flowers and colour is the ceja or bush country that fringes the tree limit on the eastern flanks of the Andes. Many of the plants recall the temperate zones, although the species are generally different. Lupines, gentians, barberries, fuchsias, viburnums, lycopodiums, buddleias, raspberries and clematis are typical types.

The high altitudes are treeless and often bleak, barren, stony and full of moors. Grasses (*Stipa*, *Festuca*, *Calamagrostis*) and rushes bulk large, while here and there peculiar relatives of the pineapple (*Puya*, *Pourretia*) form small colonies, sentinel-like in habit. *Yareta* (*Azorella*), a moss-like cushion plant of the carrot family, furnishes the dwellers in the higher altitudes with part of their fuel. Potatoes, barley, broad beans and native root crops thrive. A lichen (*Lecanora subfusca*), growing at 18,000ft., is said to be the highest altitude reached by plants in these regions.

Between the forest and the low water-line, particularly on the upper Amazon and many of its southern tributaries, but not on the Rio Negro and other "black water" rivers, large areas, often a mile or more in width, are dominated by the tall plumed canegrass, *caña brava*, a giant relative of the well-known pampas-grass. Forest and river usually meet on the "black water" rivers, and small streams of this character are often completely arched by the jungle flora of tree and vine. The grass lands largely lie between the forested valleys of the tributaries or at their head. For the most part, they are park-like in character, sprinkled here and there either with single trees, or with islands of forests from rac. to roac. or more in extent. Marshy, sluggish, plant-choked streams drain them. Cannas, water-lettuce, water-hyacinth and azolla cover enormous underwater areas, while much of the upland recalls a temperate prairie.

Some of the most valuable economic plants are indigenous to the Amazon valley. In addition to those already cited, mention should be made of quinine, cacao, cassava (*Manihot utilitissima*)

BY COURTESY OF AMAZON EXPEDITION OF THE MUSEUM OF U. OF PA.

THE INTERIOR OF A NATIVE HUT IN THE AMAZON BASIN SHOWING THE SLEEPING ARRANGEMENTS OF THE WAIWAI INDIANS OF NORTHERN BRAZIL

from which tapioca is derived, sarsaparilla, *ipecacuanha* (the source of ipecac), copaiba, tonka-beans for flavouring tobacco, arnotto (*Bixa orellana*) for colouring butter and cheese, Pará rubber (*Hevea*), balata, rosewood, snakewood, guava, calabash, coca from which cocaine is derived, chirimoya (one of the world's premier fruits), beans, pineapple and probably the tomato and potato. The giant water-lily (*Victoria regia*) is not uncommon throughout the basin below 1,000ft. altitude, while here the Brazil-nut, bignonia and the potato families attain their greatest development.

Fauna.—Although the fauna of the Amazon valley is noteworthy for the variety and number of its genera and species, it is very deficient not only in species of the larger mammals but also in the individuals of these comparatively few species. In contrast to other regions of the world, a large percentage of the mammals are tree-dwellers. None of them will attack man unprovoked, under ordinary circumstances. The monkeys are all arboreal and are common below 3,000ft. altitude. The best known are the red howlers, or *guaribas*, which make the great forest resound with their morning and evening chorus. Other common species are the spider, night, saki, marmoset, titi and squirrel-monkeys. A scarlet-faced, almost tailless species occurs near Ega. All forms are hunted and eaten by the aborigines. There are six species of the cat family, among which are the jaguar, puma or cougar and the ocelot. A small fox or fox-like dog lives on the prairies. A species of *Procyon* is described as a crab-eating racoon, and the two species of coati (*Nasua*) also belong with the racoons. The *janauhy* (*Iticyon*) or *cachorro de matto* combines the characteristics of a dog, badger, martin and beaver. Other Amazonian carnivores are the *papa-mel* (*Galictis*), kinkajou, otter, *grison* or ferret (*Grisonia*) and weasel (*Putorius*), the latter rather rare.

This region is particularly rich in rodents, the largest rodent species in the world, the capybara, being indigenous and common along the stream banks. It is said to attain a length of over 3ft. and a weight of over 50 kilograms. Other common rodents are the paca (*Coelogenys*), *cutia* or agouti (*Dasyprocta*), *sauia* or spiny rat, *toro* (*Loncheres*), several species of squirrels, rats and mice, and two species of porcupines. Paca meat is highly esteemed, but the capybara and a number of other forms are frequently used as food.

The largest animal is the *anta* or tapir, which makes its home in the giant cane-brakes along the streams. There are two species of peccary (*Dicotyles*). One of these, the *queixada* or *porco de matto*, lives in bands of 100 or more and twice invaded the small city of Obidos.

Five species of armadillos or *tatú* occur, both the giant and the pygmy species being represented. The former reaches a length of 3 feet. Of the three species of ant-eaters, two of them are tree-dwelling, while the giant ant-eater or *tamandua bandeira* is generally a prairie animal. The two sloths are both forest forms, and one species lives largely on cecropia leaves, while the other has a more varied plant diet of foliage and fruit. The flesh of the latter recalls mutton.

Four species of deer are found on the prairies and neighbouring woods, and thousands of hides are exported. The three species of opossums range in size from the *mucura*, as large as a cat, to the mouse-dimensioned *mucura chichica* with large eyes.

Bats by the million fan the Amazon night air, and represent numerous species and genera. Among them are the blood-sucking vampires (*Dysopes*, *Phyllostoma*), although these are by no means as dangerous as we are led to infer from travellers' tales.

The sea-cow or manatee is common in the lakes and hunted for its meat, which resembles pork. It is one of the most peculiar mammals of the region, with its cow-like face, its small eyes and its two large, well-developed pectoral mammae. Fresh-water dolphins of several species disport themselves in small schools.

The Avifauna is exceedingly rich. The great valley teems with species, genera and individuals. Vultures are the universal scavengers and always alert for work. Morning and evening the parrots and macaws, two by two, in brilliant aerial processions, fly to and from their feeding grounds, their gorgeous plumage flashing in the sun, and their raucous voices calling out their presence. Toucans cry at sundown a discordant plaint from some tall, trail-side tree. Through the day the hangnests or caciques quarrel in trees where their nests swing by dozens. Doves of various species dolorously coo through the hot afternoons. Hawks and eagles scream from dead tree stumps. The forest aisles ring with the clear, silvery, metallic notes of the *uirí purú* (*Pachysylvia*). At sundown *perdiz* or tinamous call out as do our quail. At night the air vibrates with the "correos" of the goat-suckers and whip-poor-wills. Early morning is full of the clatter-

ing music of the pheasant-like pavas. Hoactzins screech in noisy flocks from stream-side brush. Then there is always the twittering of legions of small birds, the sound of busy woodpeckers and the guttural noises of various water-birds. Parakeets fly about in great flocks, more common than our sparrows.

Humming-birds are not so numerous at low altitudes in the main valley, but in the Andean headwaters region, especially in the bush country, they are a striking feature of the scene. One of the common birds is the Clay-John or oven-bird, with its peculiar oven-shaped nest on a forked prairie-tree limb. Egrets roost beside the campos lakes. Muscovy and teal ducks swim about in quiet lagoons. In the marshes, the *jibirú* or great South American marabou stork is not an infrequent sight. There are two species of geese. Herons, gulls, anhingas, cormorants, roseate spoonbills, scarlet ibises and jacanas are among the common water-birds. Gorgeous trogons, cock-of-the-rocks, cotingas and tanagers are natives, while on the prairies between the Mamoré and the Beni rivers the rhea or South American ostrich is found.

One of the principal food supplies of the valley is the tartaruga turtle (*Podocnemis*). The swamps, sluggish streams and lakes usually contain one or more species of cayman. Lizards of various sizes and colours dart back and forth across the trails. The snakes, relatively speaking, are not numerous, but representatives of both poisonous groups occur (*Lachesis*, *Crotalus*, *Cophais*, *Elaps*). The constrictors (*Eunectes*, *Epicrates*) reach huge proportions, 18 to 20 ft. not being rare. Snakes, however, are not a prominent feature of Amazon life; perhaps the poisonous individuals observed are not more than one in 20 or 30. One of the deadly *Lachesis* species (rattlesnake) is considered a royal dish by the Indians. The frogs and toads abound in vivid contrasts both in shape and colouring; they are very noisy at night, and are not as edible as temperate-zone frogs.

The fish species of the Amazon have been estimated to be anywhere from 521 to 1,800 or 2,000, but only a few of them are of economic importance. Of these, the *pirarucu* is the most sought after. The scales of one species are utilized for making artificial flowers. In the half-covered forest pools, the electric eel is at home. Most of the streams are well stocked with the blood-thirsty piranha (*Serrasalmo*). Giant catfish are common and sting rays are present.

As to insects, their name in Amazonia is legion. Countless multitudes of ants work night and day. Their work varies with the species. Some are farmers like the saubas or leaf-cutters, others are always on marauding expeditions, while still others live in certain types of trees, and sting as well as bite. Termites, the so-called "white ants," abound and cause great destruction to nearly anything of wood. Fireflies with yellow, red and green lights make toy fairylands of little brooks, while a host of other insects by various devices, depending on the region, turn a paradise into purgatory. The bees are stingless, but hornets and wasps are plentiful. *Titamus giganteus*, the largest beetle known (5-6 in. long), is native. The larvae of some of the palm-beetles are relished when fried. Cockroaches are ever-present. Part of the afternoon and evening music is furnished by several species of cicadas, one of which sounds like a shrill steam whistle. Centipedes, scorpions, ticks, red bugs and giant spiders are often met with. Finally there are the moths and butterflies, hundreds of kinds and thousands of individuals, in marvellous assortments of brilliant colours and patterns. Within an hour's walk of Pará, 700 species have been collected, as compared with 321 species for all Europe. Around Ega, Bates collected 7,000 species of insects, of which 550 were species of butterflies.

AMAZONAS, the extreme north-western and largest State of Brazil, bounded north by Colombia and Venezuela, east by the State of Pará, south by the State of Matto Grosso and Bolivia, and west by Peru and Colombia. It embraces an area of 731,363 sq.m. wholly within the Amazon basin. A small section bordering the Venezuelan sierras is elevated and mountainous, but the greater part forms an immense plain, densely wooded and traversed by innumerable rivers, whose flood-plains are subject to extensive annual inundations. The climate is tropical and generally unfavourable to white settlement. The State is sparsely populated (1920) 363,166; two-thirds of the inhabitants are Indians, forming small tribes, and subject only in small part to Government control. The principal commercial products are rubber, cacao and nuts; cattle are raised on the elevated grassy plains of the north, west and south-west, while curing fish and collecting turtle eggs for their oil give occupation to many people on the rivers. Maize, manioc, rice and various fruits are produced for domestic needs. The capital, Manáos, is the only city and port of general commercial importance in the State; it is situated on the Rio Negro, 100 m. above its junction with the Amazon, about 1,000 m. from the sea. While rubber production was active along the upper Amazon Manáos attained a population of some 75,000 people (1920), but the decline in rubber gathering brought stagnation in trade and greatly reduced the number of inhabitants. There is but one railway in the State, the Madeira-Mamoré line built around the 200 m. of rapids (caxoeiras) on the Madeira river. Transportation depends upon the Amazon river and its tributaries, the Madeira, the Purús, the Jutahy, the Juruá, the Rio Negro and others, a total of some 7,500 m. of navigable waterways. Up to 1755 all the Portuguese territory on the Amazon formed part of the capitania of Pará. The upper districts were then organized into a separate capitania, called S. José do Rio Negro, to facilitate administration. When Brazil became independent in 1822, Rio Negro was overlooked in the reorganization into provinces, and reverted, notwithstanding the protests and an attempted revolution (1832) of the people, to a state of dependence upon Pará. In 1850 autonomy was voted by the general assembly at Rio de Janeiro, and on Jan. 1, 1852, the province of Amazonas was formally installed. In 1889 it became a federal state in the Brazilian republic. A governor is chosen by direct election for four years and is ineligible for immediate re-election. A single-chambered legislature of twenty-four members elected for three years exists. For purposes of internal administration the state is divided into 28 municipalities. Since the rubber crisis the state, which depended largely on export taxes on rubber for its revenue, has suffered financially and has a large bonded and floating debt. Public education is in a very rudimentary condition.

AMAZONAS, a department of northern Peru, on the eastern slopes of the Cordillera between the departments of Loreto and Cajamarca, with Ecuador on the north (area, 13,947 sq.m., estimated pop. 70,876). The north-eastern part of the territory is a low-lying equatorial virgin forest inhabited by savage tribes. The southern provinces, where the few towns are located, are more rugged. The capital, Chachapoyas, at an altitude of 7,600 ft., with about 6,000 inhabitants, has a warm, malarial climate. The chief industry is the plaiting of very fine "Panama" hats. In valleys and on lower slopes, sugar, cotton, coffee, tobacco, cacao, coca and cereals grow luxuriantly. Rainfall is abundant throughout, and the rivers, tributaries of the Marañon which crosses the department, are navigable for canoes and rafts; trails are usually impassable. The great Marañon, parent of the Amazon, crosses the eastern Cordillera at the Pongo de Manseriche (4° 30' S.), a narrow gorge only a few hundred feet wide. The mountains are rich in minerals, but remoteness from markets as well as lack of transportation facilities make these resources of little value. In Dec., 1926, a contract was signed for the construction of a railway from the coast to Yurimaguas on the Huallaga, which will pass through Chachapoyas.

AMAZONAS, a territory belonging to Venezuela, and occupying the extreme southern part of that republic, adjoining the Brazilian State of Amazonas. It lies partly within the drainage basin of the Orinoco and partly within that of the Rio Negro, an affluent

of the Amazon. The territory is covered with dense forests and is filled with intricate watercourses, one of which, the Casiquiare, forms an open communication between the Orinoco and the Rio Negro and is navigable for large canoes. The capital of the territory is Maroa, situated on the Guainia river, an affluent of the Rio Negro.

AMAZONS, a legendary nation of female warriors, said to have lived in Pontus near the shore of the Euxine sea, where they formed an independent kingdom under the government of a queen, the capital being Themiscyra on the banks of the River Thermodon (Herodotus iv. 110–117). From this centre they made numerous warlike excursions—to Scythia, Thrace, the coasts of Asia Minor and the islands of the Aegean, even penetrating to Arabia, Syria and Egypt. According to one account, they originally came to the Thermodon from the Palus Maeotis (Sea of Azov). No men were permitted to reside in their country; but once a year, in order to prevent their race from dying out, they visited the Gargareans, a neighbouring tribe. The male children who were the result of these visits were either put to death or sent back to their fathers; the females were kept and brought up by their mothers, and trained in agricultural pursuits, hunting and the art of war (Strabo xi. p. 503).

The Amazons appear in connection with several Greek legends. They invaded Lycia, but were defeated by Bellerophon (*Iliad*, vi. 186). They attacked the Phrygians, who were assisted by Priam, then a young man, though later they took his side against the Greeks under their queen, Penthesileia, who was slain by Achilles (Virgil, *Aen.* i. 490). One of the tasks imposed upon Heracles by Eurystheus was to obtain possession of the girdle of the Amazonian queen, Hippolyte. He was accompanied by his friend Theseus, who carried off the princess Antiope, sister of Hippolyte, an incident which led to a retaliatory invasion of Attica, in which Antiope perished fighting by the side of Theseus. They are heard of in the time of Alexander the Great, and Pompey is said to have found them in the army of Mithridates.

The origin of the story of the Amazons has been the subject of much discussion. While some regard them as a purely mythical people, others assume an historical foundation for them. The deities worshipped by them were Ares (who is consistently assigned to them as a god of war, and as a god of Thracian and generally northern origin) and Artemis, not the usual Greek goddess of that name, but an Asiatic deity in some respects her equivalent. Another theory is that, as the knowledge of geography extended, travellers brought back reports of tribes ruled entirely by women, who carried out the duties which elsewhere were regarded as peculiar to men. Hence arose the belief in the Amazons as a nation of female warriors, organized and governed entirely by women. It has been suggested that the fact of the conquest of the Amazons being assigned to the two famous heroes of Greek mythology, Heracles and Theseus, shows that they were mythical illustrations of the dangers which beset the Greeks on the coasts of Asia Minor; rather, perhaps, it may be intended to represent the conflict between the Greek culture of the colonies on the Euxine and the barbarism of the natives.

In works of art, combats between Amazons and Greeks are placed on the same level as, and often associated with, combats of Greeks and centaurs. Their arms were the bow, spear, axe, a half shield, nearly in the shape of a crescent, called *pelta*, and in early art a helmet, the model before the Greek mind having apparently been the goddess Athena. In later art they approach the model of Artemis, wearing a thin dress, girt high for speed; while on the later painted vases their dress is often peculiarly Persian—that is, close-fitting trousers and a high cap called the

THE MATTEI AMAZON WITH HER BATTLE EQUIPMENT. IN THE VATICAN MUSEUM, ROME

kidaris. The battle between Theseus and the Amazons is a favourite subject on the friezes of temples (e.g., the reliefs from the frieze of the temple of Apollo at Bassae, now in the British Museum), vases and sarcophagus reliefs; at Athens it was represented on the shield of the statue of Athena Parthenos, on wall-paintings in the Theseum and in the Poikile Stoa.

In the 16th century the Spanish explorer Orellana asserted that he had come into conflict with fighting women in South America on the river Marañon, which was named after them the Amazon (*q.v.*) or river of the Amazons, although others derive its name from the Indian *amassona* (boat-destroyer), applied to the tidal phenomenon known as the "bore." The existence of "Amazons" (in the sense of fighting women) in the army of Dahomey (*q.v.*) in modern times is certain, but they are said to have died out during the French protectorate.

See H. L. Krause, *Die Amazonensage* (1893); P. Lacour, *Les Amazones* (1901); articles in Pauly-Wissowa's *Realencyklopädie* and Roscher's *Lexikon der Mythologie*; Grote, *Hist. of Greece*, pt. i. ch. xi.; L. Whibley, *Companion to Greek Studies* (1916).

AMAZON-STONE or Amazonite (named from the Amazon river, its supposed locality), a bright green variety of microcline felspar (which see) obtained from Miask in the Ilmen mountains, Russia, and at Pikes Peak, Colorado, and in Madagascar.

AMBACA: see ANGOLA.

AMBALAVASI: see CASTE.

AMBARVALIA, an annual festival of the ancient Romans, occurring in May, usually on the 29th, the object of which was to secure the growing crops against harm. The priests were the Arval Brothers (*q.v.*), who conducted the victims—ox, sheep and pig (*suovetaurilia*)—in procession with prayer to Ceres round the boundaries of the *ager Romanus*. As the extent of Roman land increased, this could no longer be done, and in the Acta of the Fratres, which date from Augustus, this procession is not mentioned; but in Virgil, *Georg.*, i. 338 et seq., and in Cato's *de Re Rustica* (141) we have full details and the text of the prayers used by the Latin farmer in thus "lustrating" his own land. The Christian festival which seems to have taken the place of these ceremonies is the Rogation or Gang week of the Roman Catholic Church. The perambulation or beating of bounds is probably a survival of the same type of rite.

See W. W. Fowler, *Roman Festivals* (1899).

AMBASSADOR, a public minister of the first rank, accredited and sent by the head of a sovereign State as his personal representative to negotiate with a foreign Government, and to watch over the interests of his own nation abroad. The power thus conferred is defined in the credentials or letters of credence of which the ambassador is the bearer, and in the instructions under the sign-manual delivered to him. The credentials consist of a sealed letter addressed by the sovereign whom the ambassador represents to the sovereign to whom he is accredited, and they embody a general assurance that the sovereign by whom the ambassador is sent will confirm whatever is done by the ambassador in his name. In Great Britain letters of credence are under the royal sign-manual, and are not countersigned by a minister.

It was agreed by the Congress of Vienna, 1815, that three classes of diplomatic agents should be recognized; and a fourth class was added by the Congress of Aix-la-Chapelle. There are, therefore, now four classes of diplomatic agents:

(1) Ambassadors, including papal legates and nuncios, who enjoy the highest rank and are deemed to represent the person and dignity of the sovereign or head of their State, and who are entitled to personal access to the sovereign or head of the State to which they are accredited;

(2) ministers plenipotentiary and envoys extraordinary, including papal internuncios, who are accredited to the head of the State, and may also be resident, but who do not represent the person and dignity of the head of their own State;

(3) ministers resident, who are accredited to the head of the State, but rank below the last class in their official position and dignity; and

(4) *Chargés d'affaires* who are accredited by the Minister of

Foreign Affairs to the Minister of Foreign Affairs and who may be appointed *ad hoc* or *ad interim*. It was also agreed that diplomatic agents of the same class should take precedence according to the date of the presentation of their credentials, but in Catholic countries (except in France since the abrogation of the concordat) precedence is usually given to the papal legate. The senior minister is the *doyen* or dean of the "diplomatic corps," and it is his function to see that the diplomatic privileges and immunities are duly observed.

Ambassadors were formerly accredited only to States enjoying royal honour. Later they were accredited also to republics regarded as of equal rank. By an act of Congress in 1893 the President of the United States was empowered to accredit ambassadors to the Great Powers. Great Britain sends diplomatic agents of the first class only to 11 States, Argentina being the last so promoted.

An ambassador, however, unless specially armed with plenary authority, cannot decide any questions beyond his instructions without reference to his government. Thus Lord Londonderry (Lord Stewart), who represented Great Britain at the conferences of Troppau in 1820 and Laibach in 1821, had not the same standing as the plenipotentiaries of the other Powers present, and efforts were even made to exclude him from some of the more important discussions in consequence, not on the ground of inferior rank, but of defective powers. For the special immunities and privileges of ambassadors see EXTE RRITORIALITY and DIPLOMACY. See also the latter for the history of the subject.

BIBLIOGRAPHY.—Charles de Martens, *Manuel diplomatique* (Paris, 1822; new ed. 1868). See also Henry Wheaton, *Hist. of the Law of Nations* (New York, 1845); Sir E. Satow, *A Guide to Diplomatic Practice* (1922).

AMBASSADORS, CONFERENCE OF. The term has been used in times past to denote the sessions or reunions of ambassadors at a certain centre, generally for the period of the execution of a treaty. The best example of this is the Ambassadors' Conference which sat at Paris and Vienna during 1815–26. After the World War a similar conference meeting at Paris became one of the organs concerned with the execution of the Versailles Treaty. It consisted of the representatives of Great Britain, France, Italy and Japan, with the American Ambassador attending in the capacity of a spectator after 1921. Many of the technical decisions under the treaties were actually taken by the ambassadors, and in a large number of cases important interpretations were given.

It is difficult to give details of their activities when so much mystery obtained concerning them. Except in the case of Memel and the plebiscite areas, the complicated frontiers of Poland, left unsettled by the Peace Conference, were decided by the ambassadors. They also reorganized the frontiers established between Poland and Russia by the agreement of Riga. The most important function performed by the Ambassadors' Conference was undoubtedly in Oct. 1921, when the ex-Emperor Karl for the second time returned to Hungary with the intention of regaining his crown. The "Little Entente" (Czechoslovakia, Yugoslavia and Rumania) threatened very strong measures against Hungary. But, largely as a result of the ambassadors' intervention, Karl was arrested (Oct. 24), and a law was passed by the Hungarian Parliament which abrogated his sovereign rights (Nov. 3).

Its action in 1923, in connection with the Corfu incident, brought the conference into some discredit, and shortly after he became prime minister, Ramsay MacDonald announced that its powers would be limited to the execution of the Versailles Treaty, and this policy seems in effect to have been continued.

AMBATO or **ASIENTO DE AMBATO**, an inland town of Ecuador, capital of the province of Tunguragua, 80m. S. of Quito by the highway, and near the northern foot of Chimborazo. Pop. (1925 estimate) 25,000. The town stands in a bowl-like depression, 8,606ft. above sea-level, surrounded by steep, sandy, barren mountains, and has an equable climate. The immediate en-

virons are fertile and produce a variety of fruits, but the surrounding country is arid and sterile, producing scanty crops of barley, Indian corn and pease. The town is known throughout Ecuador for its manufacture of boots and shoes, and for a cordage made from *cabuya*, the fibre of the agave plant. Ambato was destroyed by an eruption of Cotopaxi in 1698, and has been badly damaged two or three times by earthquakes.

AMBATO is also the name of a range of mountains in northern Argentina, being a spur of the Sierra de Aconquija crossing the province of Catamarca from north to south.

AMBER, a ruined city of India, the ancient capital of Jaipur State in the Rajputana agency. The name of Amber is first mentioned by Ptolemy. It was founded by the Minas and was still flourishing in A.D. 967. In 1037 it was taken by the Rajputs, who held it till it was deserted. In 1728 it was supplanted by the modern city of Jaipur, from which it is 5m. distant. The picturesque situation of Amber at the mouth of a rocky mountain gorge, in which nestles a lovely lake, is enhanced by the beauty of its architecture. The old palace begun by Man Sing in 1600 ranks second only to Gwalior. The chief building is the Diwan-i-'Am, built by Mirza Raja, the pillars of which are still plastered over with the stucco with which Mirza had had them covered to avert the anger of Jahangir; for the emperor had been told that the sculptures on them eclipsed the marvels of the imperial city.

AMBER, a fossil resin much used for the manufacture of ornamental objects. The name comes from the Arabian *anbar*, probably through the Spanish, but this word originally referred to ambergris, which is an animal substance quite distinct from yellow amber. The property which amber possesses of acquiring electrical charge by friction is first recorded by Thales of Miletus, and suggested the word "electricity" from the Greek, *ἤλεκτρον*, a name applied, however, not only to amber but also to an alloy of gold and silver.

Amber is not homogeneous in composition, but consists of several resinous bodies more or less soluble in alcohol, ether and chloroform, associated with an insoluble bituminous substance. The average composition of amber leads to the general formula $C_{10}H_{16}O$. In concentrated sulphuric acid finely powdered amber is perfectly soluble even in the cold, and it is completely decomposed by boiling nitric acid. Heated rather below 300°C. amber suffers decomposition, yielding an "oil of amber" and leaving a black residue which is known as "amber colophony," or "amber pitch"; this forms, when dissolved in oil of turpentine or in linseed oil, "amber varnish" or "amber lac." True amber yields on dry distillation succinic acid, the proportion varying from about 3 to 8% and being greatest in the pale opaque or "bony" varieties. The aromatic and irritating fumes emitted by burning amber are mainly due to this acid. True Baltic amber is distinguished by its yield of succinic acid, for many of the other fossil resins which are often termed amber contain either none of it, or only a very small proportion; hence the name "succinite" proposed by Prof. J. D. Dana, and now commonly used in scientific writings as a specific term for the real Prussian amber.

The physical characters of amber are in every respect those of a resin. It is perfectly amorphous, as is shown by the recent X-ray investigations of Prof. F. Rinne. It occurs in irregular rounded nodules having the form of rods, drops, plates, etc., and never in masses bounded by plane surfaces. The specific gravity of amber ranges from 1.05 to 1.10; the substance is thus only slightly heavier than water. Its hardness, $H = 2\frac{1}{2}$, is a little greater than that of gypsum, and it is therefore just not possible to scratch it with the finger-nail. It is harder than most other resins but is not very brittle and can therefore be carved, worked on the lathe or bored with little difficulty. When rubbed on cloth amber becomes strongly charged with negative electricity, and attracts small light particles. It is also a very good insulator for use in electrical apparatus and is superior to sulphur because of its mechanical properties. The colouring of amber is very uniform in character, no colour but yellow occurring in the great majority of specimens, though all shades of this colour, from the palest yellow to brown, are known.

The turbidity of certain kinds of amber is due to the inclusion

of great numbers of minute air bubbles. Various other enclosures are found in amber, some of which are of special significance. Drops of water sometimes occur, but enclosures of solid matter, either organic or inorganic, are more frequent. The enclosures of organic material, partly of vegetable and partly of animal origin are of great importance, as they have thrown much light on the flora and fauna existing at the time of the exudation of the amber.

Amber is extensively used for beads and other small ornaments, and for cigarette-holders and the mouth-pieces of pipes. Small fragments, formerly thrown away or used only for varnish are now utilized on a large scale in the formation of "ambroid" or "pressed amber." The pieces are carefully heated with exclusion of air and then compressed into a uniform mass by intense hydraulic pressure. Rods of amber are then obtained by forcing the mass of softened amber through holes in a metal plate. The product possesses practically the same physical properties as natural amber.

The greatest amber-producing region is the promontory of Samland in East Prussia, where the amber occurs in a marine glauconitic sand, known as "blue earth," occurring in the Lower Oligocene strata. It appears, however, to have been partly derived from yet earlier Tertiary deposits (Eocene) and it occurs also as a derivative mineral in later formations, such as the drift. Rolled pieces of amber may be picked up at various places along the east coast of England and also on the coasts of Holland, Denmark, Sweden, in Bornholm and other islands and in South Finland. Varieties of amber differing slightly from succinite are found in Rumania, Sicily and Burma.

Soc.*, vols. iii. (1884) and iv. (1886).

(W. A. W.)

AMBERG, a town in Bavaria, formerly capital of the Upper Palatinate, on both sides of the Vils, 42m. E. of Nürnberg by rail. Pop. (1925) 26,337. It has eleven churches; St. Martin's (15th century) has good paintings and a tower 300ft. high. A former Jesuit monastery is now a grammar school and seminary. There is also a pilgrimage church on a hill (1,621ft.). The principal manufactures are enamels, ironmongery and machinery, gold objects and furniture. In the neighbourhood are iron and coal mines. The Austrians defeated the French near Amberg in 1796.

AMBERGRIS, a solid, fatty, inflammable substance of a dull grey or blackish colour, the shades being variegated like marble, possessing a peculiar sweet, earthy odour. It occurs as a biliary concretion in the intestines of the spermaceti whale (*Physeter catodon*), and is found floating upon the sea, on the sea-coast or in the sand near the sea-coast. It is met with in the Atlantic ocean; on the coasts of Brazil and Madagascar; also on the coast of Africa, of the East Indies, China, Japan and the Molucca islands; but most of the ambergris which is brought to England comes from the Bahama islands, Providence, etc. It is sometimes found also in the abdomen of whales, always in lumps of various shapes and sizes, weighing from one-half oz. to 100 or more pounds, having a disagreeable smell, and hardening on exposure to air. Its specific gravity ranges from 0.780 to 0.926. It melts at about 62°C. to a fatty, yellow, resinous-like liquid; and at 100° C. it is volatilized into a white vapour. It is soluble in ether, and in volatile and fixed oils; it is only feebly acted on by acids. By digesting in hot alcohol, a substance termed *ambrein*, closely resembling cholesterin, is obtained, which separates in brilliant white crystals as the solution cools.

The use of ambergris in Europe is now entirely confined to perfumery. In minute quantities its alcoholic solution is much used for giving a "floral" fragrance to bouquets, washes and other preparations of the perfumer. It occupies a very important place in the perfumery of the East, and there it is also used in pharmacy and as a flavouring material in cookery. The high price it commands makes it peculiarly liable to adulteration, but its

genuineness is easily tested by its solubility in hot alcohol and its uniform fatty consistence on being penetrated by a hot wire.

AMBIDEXTERITY, the ability to use both the right and the left hand with equal ease (Lat. *ambi* both, *dexter* right-handed). Educationalists and physiologists frequently advocate the cultivation of ambidexterity in children on the ground that the brain-centres controlling the motor functions thereby become more highly developed. Since, however, the left hemisphere of the brain controls both the function of speech and the motor functions of the right side, over-development of left-handedness has been known to cause speech impediment and must be avoided.

See F. W. Mott, *The Brain and the Voice in Speech and Song* (1910); H. Macnaughton Jones, *Ambidexterity and Mental Culture* (1914).

AMBIENT (Lat. *ambi*, on both sides, *ire*, to go), surrounding; a word implying a moving rather than a stationary encircling. It is used mostly in the phrase the "ambient air." In astrology it means the sky.

AMBIGU, a French game of cards in which a whist pack with the court cards omitted is used. It is composed of the characteristic elements of whist, bouillotte and piquet.

AMBIGUITY, in law, is of two kinds, *patent* and *latent*. (1) Patent ambiguity is that which is apparent on the face of an instrument to anyone perusing it. In the case of a patent ambiguity parol evidence is admissible to explain only what has been written, not what it was intended to write (*Garrard v. Lewis* [1882] 10 Q.B.D. 30). Where it appears from the general context what the parties really meant, the instrument will be construed as if there were no ambiguity (*Saye and Sele's case* 10 Mod. 46; *De Rosaz, in the Goods of* [1877] 2 P.D. 66). (2) Latent ambiguity is where the wording of an instrument (on the face of it clear and intelligible) may at the same time apply equally to two different things or subject matters. Latent ambiguity may be explained by parol evidence, as the ambiguity has been brought about by circumstances extraneous to the instrument (*Doe D. Thomas v. Beynon* [1840] 12 Ad. and E. 431). But a contract that is void for uncertainty will not be rendered certain by part performance (*Waring and Gillow v. Thompson* [1913] 29 T.L.R. 154 C.A.). (See also CONTRACT; EVIDENCE; PRINCIPAL AND AGENT.)

AMBIORIX, prince of the Eburones, a tribe of Belgian Gaul. Although Caesar (q.v.) had freed him from paying tribute to the Aduatuci, he joined Catuvolcus (winter, 54 B.C.) in a rising against the Roman forces under Q. Titurius Sabinus and L. Aurunculeius Cotta, and almost annihilated them. An attack on Quintus Cicero (brother of the orator), then quartered with a legion in the territory of the Nervii, failed owing to the timely appearance of Caesar. Ambiorix is said to have found safety across the Rhine.

BIBLIOGRAPHY.—Caesar, *Bell. Gall.*, v. 26–51, vi. 29–43, viii. 24; Dio Cassius xl. 7–11; Florus iii. 10.

AMBLESIDE, urban district of Westmorland, England, a mile from the head of Lake Windermere. Population (1931) 2,343. It is beautifully situated among the bare hills surrounding the richly wooded valley of the Rothay. The hills are Wansfell on the east, Loughrigg Fell on the west, and Rydal Fell and the ridge below Snarker Pike (2,096ft.) to the north. At the head of Windermere is Waterhead, the landing-stage of Ambleside, which is served by the lake steamers of the L.M.S.R. The chief roads centring in Ambleside are from Windermere, Ullswater, Keswick, the Brathay valley and the Langdales to the west. There are slate quarries in the neighbourhood.

Close by the lakeside the outlines of a Roman fort, the name of which is not known, are still visible. It appears to have guarded a route over the hills by Hardknott and Wrynose pass to Raven-glass on the coast of Cumberland.

AMBLYGONITE, a mineral usually found as cleavable, compact masses; it is translucent and has a vitreous lustre, and the colour varies from white to pale shades of violet, grey, green or yellow. There are good cleavages in two directions. The mineral is thus not unlike felspar in general appearance, but it is readily distinguished from this by its specific gravity (3.0) and

chemical characters, being an aluminium and lithium fluophosphate, $\text{Li}(\text{AlF})\text{PO}_4$, with part of the lithium replaced by sodium and part of the fluorine by hydroxyl. Amblygonite occurs with lepidolite, tourmaline and other lithia-bearing minerals in pegmatite-veins. It was first discovered in Saxony in 1817, and later at Montebras, dep. Creuse, France, and at Hebron in Maine. More recently it has been discovered in considerable quantity at Pala in San Diego county, California, and at Cáceres in Spain.

AMBLYOPIA is a somewhat indefinite term meaning dimness of vision, or loss in the acuity of sight. It is usually restricted to those cases of dim vision which are not due to refractive errors such as can be corrected by glasses and to cases in which there are no visible changes in the exterior or interior of the eye. Loss of vision may be partial or total, temporary or permanent. Total blindness is usually called amaurosis. The symptom may come on suddenly, with immediate total loss of sight, or gradually, with a sense of a blue veil or mist before the eyes, or it may not be noticed until the patient suddenly finds he cannot read. Colour blindness, night blindness, and day blindness are varieties of amblyopia. The causes may be injury to the brain, disease of the nervous and retinal structures involved in vision, drugs, and the poisons of certain diseases, such as chronic nephritis, acute nephritis, toxemias of pregnancy, diabetes and malaria. Other common causes are intoxicating liquor, tobacco, lead, quinine and wood alcohol. It has long been recognized as a manifestation of hysteria and many cases were encountered during the war in soldiers suffering from "shell shock."

AMBLYPODA, an extinct order of hoofed mammals. They inhabited North America, Europe and Asia during the early part of the Tertiary period and were the largest quadrupeds of their time. The limbs and feet were like those of elephants, long, straight, postlike legs with short, rounded, five-toed feet, small hoofs with heavy elastic pads to support the weight of the animal. The skull was massive with short-crowned cheek teeth of a peculiar lophodont or cross-crested pattern and enlarged canine tusks which, in one group, suggest those of pigs, in another those of the tusked deer. These tusks had no likeness to the incisor tusks of elephants. The brain was small.

Although they resembled the elephants in the general character of the limbs, the structure of wrist and ankle bones precludes any near relationship; moreover the characters of skull and teeth were quite peculiar. The *Amblypoda* appear to have evolved from primitive ancestors related to the *Condylarthra*, and are connected with them through a number of intermediate types of

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
SKELETON OF A UINTATHERIUM, OR DINOCERAS, THAT ROAMED WYOMING MILLIONS OF YEARS AGO IN THE MIDDLE EOCENE PERIOD

Palaeocene mammals. *Coryphodon* of the Lower Eocene (Europe and North America) was about the size of the larger bears. The front teeth were enlarged; the stout flaring tusks and heavy muzzle suggesting the hippopotamus; the skull broad-topped and roughened; the proportions of the body much as in the bears; the tail rather small. The premolar teeth had crescentic cusps; the true molars a combination of crescents and curving crests of unique pattern.

The *Uintatheres* or *Dinocerata* of North America were the most specialized and largest of the *Amblypoda*. In these the upper in-

cisors were absent; the upper canines enlarged into great dagger-like tusks; the cheek teeth small with a distinctive pattern of crescents and crests; and the top of the skull bore two or three pairs of stout prominent bony bosses or "horns" analogous to the horns of the giraffe. This group first appears in the Palaeocene of North America and Central Asia with small ancestral types no larger than a pig—hornless; but already showing the characteristic pattern of tusks and cheek teeth.

Bathyopsis of the Lower Eocene was somewhat larger; still hornless; but with rudimentary bosses on the skull. *Uintatherium* (*Dinoceras*) of the Middle Eocene had two pairs of horns, one over the orbits, the other near the back of the skull. It was as large as a small rhinoceros. *Eobasilus* (*Loxolophiodon*) of the Upper Eocene had a third pair of horns above the nasals, and the size of the two other pairs increased. This animal attained the size of the largest rhinoceros. The brain remained quite undeveloped, very small in contrast to the huge massive skull.

(See PALAEOLOGY.)

(W. D. M.)

AMBO, the reading-desk of the early Christian church, originally movable, but by the 6th century established as an important and stationary piece of great decorative value. From the 12th century on, and earlier than that outside Italy, the ambo was more and more superseded by the pulpit and lectern, and even in Italy it has gone out of liturgical use, except in the Ambrosian rite in Milan. The normal single ambo consisted of a raised platform in three levels, reached by steps and protected by railings. Each level was consecrated to a special part of the service: the highest, reserved for the deacon who read the gospel; the middle, for the deacon reading the epistle; the lowest, for the subordinate clergy. Later, two separate ambones were used, one on each side of the church; the one to the south was used for reading the gospel, the other for the epistle.

These ambones were usually composed as part of the choir screen, and, like it, were, in all the finer churches, made of marble, frequently decorated with mosaics and carving. A normal type is represented by those in San Clemente at Rome (see illustration under BASILICA) which are at least as old as the beginning of the 12th century; others of great interest, of later date, and rich with that fine-scaled geometric mosaic known as Cosmati work, are those of Sta. Maria-in-Ara-Coeli, Sta. Maria-in-Cosmedin and San Lorenzo outside the walls, all of the 12th or 13th century. Outside of Rome, although Ravenna has early examples, it is in south Italy that the finest are found; notably that of Ravello (1130), and that of Salerno. In south Italy it is the rule to have the ambones supported on spiral columns; in Rome the base is usually solid.

In the Eastern Church, the ambo is slightly different. In Russian orthodox usage the term usually designates the steps leading to the platform in front of the iconostasis (*q.v.*). In the Greek Church the ambo retains its earlier form, and is placed at one side of the church; but in the Greek Catholic Church, the ambo is a table before the doors of the iconostasis.

See the liturgical and ecclesiastical dictionaries of Martigny, Migne, and Smith and Cheetham, *sub voce*.

AMBOIM: see ANGOLA.

AMBOINA is a Dutch Residency of the Government of the Moluccas, area 198,367 sq.km., and is the name of the capital and the island on which it is situated. Formerly a separate residency, in 1927 it was united with Ternate Residency to form the Government of the Moluccas. Amboina includes the island of that name, Saparua (with Haruku, Oma, Melano and Nusa Laut—the Uliassers); Kajeli (Buru); Masareti (Buru); Kairatu (Ceram); Waihai (North mid-Ceram); Amahai (South mid-Ceram); the Banda Isles, with East Ceram, Ceram Laut and the Goram Archipelago; the islands of Aru, Ké, and Tenimber, or Timor Laut; West and South New Guinea, and the South-Western Islands. Pop. (1925) 358,250, comprising 2,808 Europeans (including Eurasians), 350,192 natives, and 5,250 foreign Asiatics, including Chinese. The area is about 20,000sq.m. Imports (1925) 3,717,778 guilders; exports 4,152,141. Amboina lies S.W. of Ceram, N. of the Banda Sea. Two oblong peninsulas, Hitoe much larger than Leitomor, rise parallel from the sea, and are

united by a narrow alluvial isthmus not more than a mile long. The total length of the island is 32m., and its area is 386sq.m. It is subject to damage from earthquakes and volcanic eruptions as are the neighbouring isles to the east, the Uliassers (pop., 20,000, largely Christian). Amboina is of Tertiary (Miocene) formation, and is traversed by mountain ranges (highest peaks Salhatu, 4,929ft., and Wawani) of fine-grained granite, with serpentine, magnesite, etc. The chalk cliffs round Amboina Bay have stalactite caves; the rivers are small and unnavigable, there are hot springs and solfataras, but no active volcanoes. The climate is comparatively healthy and not unpleasant, the mean maximum temperature being 84.6° and the mean minimum 73.4°, whilst a minimum of 66.6° has been registered. The hottest time is in February, the wettest in June–July (during the east monsoon with very strong winds) and the average yearly rainfall is 135.63 in. The mammalian fauna of Amboina is very poor, but birds include a fine racquet-tailed kingfisher, *Tanysiptera nais*, described by A. R. Wallace as "the largest and handsomest" of this family. It has also a crimson lory, *Eos rubra*, and a brush-tongued parrot, of vivid crimson colour, and it is rich in insects, particularly Lepidoptera, and in shells. There are 700 varieties of fish in the Bay of Amboina, under which, at the eastern end, are very fine marine gardens. The profuse vegetation varies on different sides of the island. Spice trees are grown, principally clove and nutmeg, fruit trees, and coconut palms, maize, sugarcane, rice, also coffee and cocoa. Cloves and copra are the chief exports. The natives live largely on fruit and vegetables and sago—the sago being imported from Ceram. Amboina wood, very hard and knotty, and of great value for ornamental wood-work, is obtained from Ceram, and exported. Goats and sheep are kept, and pigs in the Christian villages, fishing provides a living for a numerous class, and shells and turtle-shells are collected. Pop. 114,297 (Europeans and Eurasians 2,290), almost entirely Christian in the south and Mohammedan in the north. The Amboinese are a strong and thick-set race, with dark skin, curly or wavy hair, flat nose and thick lips. The women are slender in build, but not good-looking. The men wear a cotton jacket and trousers; the women a *sarong* and *kabaya*.

Amboina, the town, and residence of the Resident and Commander of the forces in the Moluccas, is a clean and well-built place, with wide, straight streets, often tree-lined, and many houses and business premises of stone; Ft. Victoria, built in the early 17th century and restored later; a church dating from the earliest settlement, a hospital, barracks (within the fort), and many Government buildings, a commodious club, and two good parks. In Amboina G. E. Rumph (Rumphius) the well-known naturalist, lived and died, and a monument commemorates the fact. The town is at the head of the bay, which, at its entrance, is 5½m. in width and continues so for 10m., when it contracts and forms a narrow passage leading into an inner harbour 3m. long by 1¼ broad. The town and port is on the eastern side of the bay, a mile short of the entrance to the inner harbour and about 8m. from the outer entrance. The depths in the outer bay are very great and anchorages are few, but safe. The port is well equipped with wharves and warehouses, has a regular connection with Java, Sumatra, Borneo and Celebes, as well as with the rest of the archipelago, and is the chief centre for the shipment of Moluccan produce and for the distribution of imports from Europe and America. Pop. 11,726—1,453 Europeans (and Eurasians), 8,804 natives, and 1,469 foreign Asiatics, including Chinese, engaged in agriculture, fisheries and trade. There are roads sufficient for local needs, a government wireless station and a telephone system.

The clove trade of Amboina led the Portuguese to the island, Antonio d'Abreu arriving there and departing with a cargo of cloves in the same year (1510) as that in which Albuquerque captured Malacca. The Portuguese gave the place its name and founded a settlement (1521), but their policy of ruthless repression made it easy for the Dutch to arrange with the Sultan of Ternate, recognizing him as suzerain over Amboina and other Moluccan islands, and, in 1600, with the chiefs of Amboina. This enabled them first to dispossess the Portuguese and then to bring the Amboinese within their power. In 1615 a British

settlement was formed on the other side of the island at Cambello (the Dutch were on the Amboina town site) and it remained there until 1623, when the Dutch, who aimed at establishing a clove monopoly, claimed to have discovered British participation in a native revolt in Ceram, and in the Bandanese island of Run, and massacred the settlers. The massacre was unnoticed by James I., but in 1654 Cromwell compelled the Dutch government to give the sum of £300,000, and the island of Run, as compensation to the descendants of those who had suffered. Dryden (1673) wrote a tragedy, *Amboyna, or the Cruelties of the Dutch to the English Merchants*. In 1683 the Dutch declared all contracts with the Sultan of Ternate void, and took over his suzerainty of Moluccan islands, Amboina included. In 1796 the British, under Admiral Rainier captured the island, but it was restored in 1802, re-taken in 1810, during the Napoleonic War, and once again restored to the Dutch in 1814. (E. E. L.)

Martin, *Reisen in den Molukken, in Ambon, den Uliassern, Seran, und Buru* (Leyden, 1894); O. Beccari, *Nuova Guinea, Selebes, e Molucche* (Florence, 1924).

AMBOISE, GEORGES D' (1460–1510), French cardinal and minister of State, was the son of Pierre d'Amboise, seigneur de Chamont, chamberlain to Charles VII. and Louis XI. Georges d'Amboise was bishop of Montauban, then archbishop of Narbonne, and then (1493) of Rouen. On the accession of Louis XII., to whose party he had belonged before Louis was king, D'Amboise became a cardinal and first minister of the crown. His domestic policy was wise and prudent. In foreign affairs he was animated by two aims—to increase the French power in Italy and to seat himself on the papal throne; and these aims he sought to achieve by diplomacy, not by force. He, however, sympathized with, and took part in, the campaign which was begun in 1499 for the conquest of Milan. In 1500 he was named lieutenant-general in Italy and charged with the organization of the conquest. On the death of Alexander VI. he aspired to the papacy. He had French troops at the gates of Rome, by means of which he could easily have frightened the conclave and induced them to elect him; but he was persuaded to trust to his influence; the troops were dismissed, and an Italian was appointed as Pius III.; and again, on the death of Pius within the month, another Italian, Julius II., was chosen (1503). D'Amboise received in compensation the title of legate for life in France and in the Comtat Venaissin. He was one of the negotiators of the disastrous treaties of Blois (1504), and in 1508 of the League of Cambrai against Venice. In 1509 he again accompanied Louis XII. into Italy, but on his way home he died at Lyons on May 25, 1510. His body was removed to Rouen, and a magnificent tomb, on which he is represented kneeling in the attitude of prayer, was erected to his memory in the cathedral.

Lavis, *Histoire de France* (vol. v. by H. Lemonnier, 1903). For a bibliography of the printed sources, see H. Hauser, *Les Sources de l'histoire de France, XVI^e siècle*, vol. i. (1906).

AMBOISE, a town of France, dept. of Indre-et-Loire, on the left bank of the Loire, 12m. E. of Tours by the Orléans railway. Pop. (1926) 4,284. Its famous château overlooks the Loire from the rocky plateau above the town. In the 11th century Amboise was a lordship under the counts of Anjou, who rebuilt the ancient castle. Its territory was united to the domain of the crown of France by Charles VII. about the middle of the 15th century, and thenceforth the château became a favourite residence of the French kings. The discovery in 1560 of the "conspiracy of Amboise," a plot of the Huguenots to remove Francis II. from the influence of the house of Guise, was avenged by the death of 1,200 members of that party. In 1563 Amboise gave its name to a royal edict allowing freedom of worship to the Huguenot nobility and gentry. The château was frequently used as a state prison. In 1872 it was restored by the National Assembly to the house of Orléans. The Logis du Roi, the most important portion, was the work of Charles VIII.; the other wing was built under Louis XII. and Francis I. The ramparts are strengthened by two massive towers containing an

inclined plane on which horses and carriages may ascend. The chapel of St. Hubert, said to contain the remains of Leonardo da Vinci, who was summoned to Amboise by Francis I., king of France, and died there in 1519, is late Gothic; a delicately carved relief over the doorway represents the conversion of St. Hubert. The town has a 15th-century gateway surmounted by a belfry. Iron-founding, wool-weaving and the manufacture of boots and

AMBOISE, FRANCE. SCENE OF MANY STIRRING HISTORIC EVENTS, WITH THE CHATEAU, FAMOUS AS A RESIDENCE OF THE FRENCH KINGS, IN THE LEFT BACKGROUND

shoes, sabots, and farm and fishing implements are among the industries.

AMBRACIA (more correctly Ampracia), an ancient Corinthian colony in Epirus about 7m. from the Ambracian gulf, on the navigable river Aracthus, in a fertile wooded plain. It was founded between 650 and 625 B.C. by Gorgus, son of the Corinthian tyrant Cypselus. After expulsion of Gorgus's son Periander its Government developed into a strong democracy. Early features were loyalty to Corinth, consequent aversion to Corcyra, and frontier disputes with Amphilochians and Acarnanians. Hence it took a prominent part in the Peloponnesian War until the defeat at Idomene (426). In 338 it surrendered to Philip of Macedon. After forty-three years of autonomy under Macedonian suzerainty it became the capital of Pyrrhus, king of Epirus, who adorned it with a palace, temples and theatres. In the wars of Philip V. of Macedon and the Epirotes against the Aetolian league (220-205), Ambracia ultimately joined the Aetolians, and during their struggle against Rome it stood a stubborn siege. After its capture in 189, it fell into insignificance. The foundation by Augustus of Nicopolis (*q.v.*), into which the remaining inhabitants were drafted, left the site desolate. In Byzantine times a new settlement took its place under the name of Arta (*q.v.*).

AMBRIDGE, a borough of Beaver county, Pa., U.S.A., on the Ohio river and the Pennsylvania railroad, 16 m. N.W. of Pittsburgh, opposite to the borough of Woodlawn. It lies on a wide plain, 755ft. above sea-level, and 70ft. above the river. The population in 1920 was 12,730, of whom 4,545 were foreign-born whites, and was 20,227 in 1930 Federal census. Its factories in 1925 produced 575,798 tons of finished products, valued at \$58,536,511, including such commodities as structural steel for bridges, buildings and barges; bare and insulated wire and cable; flexible steel conduit, carburettor tubing, asbestos-protected metal, electric conduit and fittings, pig-casting machines, cold finished steel, mining and coal-handling machinery, skylights and ventilators.

Within the boundaries of Ambridge is the former village of Economy, founded in 1824 by the Harmony Society, under its leader, George Rapp, the German Communist. Under Rapp and his successor, R. L. Baker, the community built up substantial agricultural and manufacturing industries; but after 40 or 50

years the rule of celibacy and the lack of fresh converts resulted in dwindling numbers, and in 1906 the society was disbanded. Many of the original buildings are still standing, including the Great House, which is now owned by the State of Pennsylvania and maintained as an historical museum.

Ambridge was incorporated as a borough from part of Harmony township in 1905. It has a city-manager form of government.

AMBROS, AUGUST WILHELM (1816-1876), distinguished musical historian, was born at Vysoké Myto, Bohemia. From 1850 onwards he became well known as a critic and essay-writer, and in 1860 he began working on his *magnum opus*, his *History of Music*, which was published at intervals from 1864 in five volumes, and reissued in a revised and enlarged edition in 1909. Ambros became professor of the history of music at Prague in 1869, and later occupied a similar position at Vienna, where he died.

AMBROSE, SAINT (340?-397), bishop of Milan, one of the greatest Fathers of the Church, was born a Roman citizen about 337-340 in Trèves, where his father was prefect of Gallia Narbonensis. His mother was a woman of intellect and piety. Ambrose was intended to follow his father's career and accordingly educated in Rome. He became consular prefect of Liguria and Emilia, with headquarters at Milan, where he made an excellent administrator. In 374 Auxentius, bishop of Milan, died, and the orthodox and Arian parties contended for the succession. An address delivered to them at this crisis by Ambrose led to his nomination to the see; though only a catechumen, he was baptized and duly installed as bishop of Milan. Having apportioned his money among the poor, he settled his lands upon the Church, but leaving his sister Marcellina tenant for life and committing the care of his family to his brother, he entered upon a course of study under Simplician, a presbyter of Rome, and devoted himself to the labours of the episcopate. An invasion of Goths compelled Ambrose and other churchmen to retire to Illyricum for a time. His eloquence soon found ample scope against the Arians. Gratian, the son of the elder Valentinian, took the same side; but the younger Valentinian, now a colleague in the empire, adhered to the Arians, and Ambrose failed to win him to orthodoxy. The Arian leaders Palladius and Secundianus, confident of numbers, persuaded Gratian to call a general council from all parts of the empire; but Ambrose in the end prevailed upon the emperor to remit the matter to a council of the Western bishops alone. A synod, composed of 32 bishops, was held at Aquileia in the year 381. Ambrose was elected president; and Palladius, being called upon to defend his opinions, declined, insisting that the meeting was a partial one, and that, since not all the bishops of the empire were there, the sense of the whole Christian Church could not be manifest. A vote was then taken, and resulted in Palladius and Secundianus being deposed.

Ambrose was zealous in combating the pagan reaction. Quintus Aurelius Symmachus, consul in 391, besought Valentinian II. to set up again the altar of Victory in the hall of the senate, to provide for the support of seven vestal virgins and to revive the pagan ceremonies. Ambrose, in a letter to Valentinian, countered this petition: both documents are extant.

Although the court rejected the religious tenets of Ambrose, it respected his statesmanship. When Maximus usurped supreme power in Gaul and meditated a descent upon Italy, Valentinian sent Ambrose to dissuade him: Ambrose was successful. On a second attempt of the same kind Ambrose was unsuccessful; the enemy entered Italy; Milan was taken. Justina and her son fled; Ambrose remained, and for the relief of the suffering populace he did not hesitate to cause the consecrated vessels used in the most sacred rites of the Church to be melted down: a memorable precedent often to be cited in Church history. Theodosius, the emperor of the East, espoused the cause of Justina, and regained the kingdom.

In 392, after the assassination of Valentinian and the usurpation of Eugenius, Ambrose fled; but when Theodosius proved victorious, the saint became a suppliant to the emperor for the pardon

of those who had followed Eugenius. Theodosius died at Milan in 395, and two years later (April 4, 397) Ambrose also passed away.

A man of pure character, vigorous mind, unwearying zeal and uncommon generosity, Ambrose ranks among the Fathers of the ancient Church, with Augustine, Jerome, and Gregory the Great; as one of the Latin "doctors," he is fitly compared with Hilary, whom he surpasses in statesmanship, if he falls below him in theology. Even in theology, however, his achievements are of no mean order, especially when we remember his juridical training and his comparatively late handling of Biblical and doctrinal subjects. In matters of exegesis he is, like Hilary, an Alexandrian; his chief productions are homiletic commentaries on the early Old Testament narratives, e.g., of the Hexaëmeron and of Abraham, some of the Psalms, and the Gospel according to Luke. In dogmatic he follows Basil of Caesarea and other Greek authors, but nevertheless gives a distinctly Western cast to the speculations of which he treats. This is particularly manifest in the emphasis which he lays upon human sin and divine grace, and in the place which he assigns to faith in the individual Christian life. His chief works in this field are *De fide ad Gratianum Augustum*, *De Spiritu Sancto*, *De incarnationis Dominicae sacramento*, *De mysteriis*. His great spiritual successor, Augustine, whose conversion was helped by Ambrose's sermons, owes more to him than to any writer except Paul. Ambrose's intense realization of the dignity of the episcopal office furthered the growing doctrine of the church and the *sacerdotium*, while the prevalent asceticism of the day, continuing the Stoic and Ciceronian training of his youth, enabled him to promulgate a lofty standard of Christian ethics. Thus we have the *De officiis ministrorum*, *De viduis*, *De virginitate* and *De paenitentia*.

Ambrose has also left several funeral orations and 91 letters. Catching the impulse from Hilary and confirmed in it by the success of Arian psalmody, Ambrose composed several hymns, marked by dignified simplicity, which served as a fruitful model for later times. We cannot certainly assign to him more than four or five (*Deus Creator Omnium*, *Aeternae rerum conditor*, *Jam surgit hora tertia*, and the Christmas hymn *Veni redemptor gentium*) of those that have come down to us. Each of these hymns has eight four-line stanzas and is written in strict iambic tetrameter. The attribution of the *Te Deum* to him, either as sole author or in collaboration with St. Augustine, has long since been discredited by all competent scholars.

AMBROSE (c. 1190), Norman poet, chronicler of the third crusade and author of a work called *L'Estoire de la guerre sainte*, which describes in rhyming French verse the adventures of Richard Cœur de Lion as a crusader. The poem is known to us only through one Vatican ms., and the credit for detecting its value belongs to Gaston Paris, although his edition (1897) was partially anticipated by the editors of the *Monumenta Germaniae Historica*, who published some selections in the 27th volume of their *Scriptores* (1885).

Ambrose followed Richard I. as a non-combatant, and not improbably as a court minstrel. He is surprisingly accurate in his chronology; though he did not complete his work before 1195, it is evidently founded upon notes which he had taken in the course of his pilgrimage. He is rather to be treated as a biographer than as a historian of the crusade in its broader aspects. None the less he is the chief authority for the events of the years 1190-92, so far as these are connected with the Holy Land. The *Itinerarium Regis Ricardi* (formerly attributed to Geoffrey Vinsauf, but in reality the work of Richard, a canon of Holy Trinity, London) is little more than a free paraphrase of Ambrose. Stubbs's edition of the *Itinerarium*. (Rolls series.

1864) in which it is treated as an independent work, appeared before Gaston Paris published his discovery.

See the edition of *L'Estoire de la guerre sainte* by Gaston Paris in the *Collection des documents inédits sur l'histoire de France* (1897); the editor discusses in his introduction the biography of Ambrose, the value of the poem as a historical source, and its relation to the *Itinerarium*. R. Pauli's remarks (in *Monumenta Germaniae Historica. Scriptores*, xxvii.) also deserve attention. (H. W. C. D.)

AMBROSE (ANDREY SERTIS-KAMENSKIY) (1708-1771), archbishop of Moscow from 1761 to 1771, was famous for his interest in schemes for the alleviation of poverty in Moscow and as the founder of new churches and monasteries. A terrible outbreak of plague occurred in Moscow in 1771, and the populace began to throng round an image of the Virgin to which they attributed supernatural healing power. Ambrose, seeing that the crowding together spread the contagion, had the image secretly removed. The mob, suspecting that he was responsible for its removal, attacked a monastery to which he had retired, dragged him away from the sanctuary, and, having given him time to receive the sacrament, strangled him. Ambrose's works include a liturgy and translations from the Fathers.

AMBROSE (AMBROISE), AUTPERT (d. 778), French Benedictine monk. He became abbé of St. Vincent on the Volturno "in the time of Desiderius, king of the Lombards." He wrote commentaries on the Apocalypse (see *Bibl. Patrum*, xiii. 403), on the Psalms, on the Song of Solomon; *Lives of SS. Paldo, Tuto and Vaso* (according to Mabillon); *Assumption of the Virgin*; *Combat between the Virtues and the Vices*.

BIBLIOGRAPHY.—Mabillon, *Acta sanct.* Bolland. III. ii. 259, 266; Georg Lommel, *Der ostfränkische Reformator Ambrosius* (Giessen, 1847); Bollandist *Bibl. hag. lat.* (1898), 61.

AMBROSE, ISAAC (1604-1663-4), English Puritan divine, vicar of Preston. Ambrose left his great church of Preston in 1654 and became minister of Garstang, whence he was ejected in 1662 with the two thousand ministers who refused to conform. As a religious writer Ambrose has a vividness and freshness of imagination possessed by scarcely any of the Puritan Nonconformists. His *Looking to Jesus* long held its own in popular appreciation with the writings of John Bunyan.

AMBROSE THE CAMALDULIAN, the name by which Ambrogio Traversari (1386-1439), Italian humanist and ecclesiastic, is commonly known. Ambrogio was born at Portico, near Florence, and studied Greek under Emmanuel Chrysoloras. He entered the Camaldulian Order at 14, and became general of the order in 1431. His great work was the introduction of the Greek theologians' works to the church of the Renaissance by a series of translations to which he devoted his life. Those writings of the fathers which were available were often rendered into obscure and barbarous Latin, and many had not been translated at all. He produced a new version of the homilies of St. Chrysostom and of others of his works, and translations of Dionysius the Areopagite and other authors. Many of his mss. are preserved in the library of St. Mark's, Venice. He was a friend of Cosmo de Medici, at whose desire he reluctantly turned aside from the Greek fathers for a moment to make a Latin version of Diogenes Laertius. He died on Oct. 20 1439.

See G. Voigt, *Die Wiederbelebung des klass. Altertums*, 3rd ed. (1893); his *Epistolae* were published by Cannato (Florence, 1759) with a life by Mehus; Bollandist *Bibl. hag. lat.* (1898), 63; A. Masius, *Über die Stellung des Kamaldulensers Ambrogio Traversari zum Papst Eugen IV. und zum Basler Konzil* (Döbeln, 1888); Savigny, *Geschichte röm. Rechts im Mittel.* (1850), vi. 422-424.

AMBROSIA, in ancient mythology, sometimes the food, sometimes the drink, of the immortals. The word has generally been derived from Gr. *ἀ-*, not, and *μ(β)ροτός*, mortal. A. W. Verrall, however, denies that there is any clear example in which the Greek word *ambrosios* necessarily means "immortal," and explains it as "fragrant," a sense which is always suitable. If so, the word may be derived from the Semitic *ambar* (ambergris), to which Eastern nations attributed miraculous properties. W. H. Roscher thinks that both nectar and ambrosia were kinds of honey. The name *Ambrosia* was also later applied by Dioscorides and Pliny to certain herbs, and has been retained in modern botany for a genus of plants from which it has been extended to the group

of dicotyledons called *Ambrosiaceae*, including *Ambrosia*, *Xanthium*, and *Iva*, all annual herbaceous plants represented in America. *Ambrosia maritima* and some other species occur also in the Mediterranean regions.

There is also an American beetle, the Ambrosia beetle, belonging to the family of Scolytidae, which derives its name from its cultivation of a succulent fungus, called ambrosia. Ambrosia beetles bore galleries into timber, and the wood-dust provides a bed for the fungus on which the insects and larvae feed.

AMBROSIAN CHANT, a general term applying to the particular type of liturgical music associated with the name of St. Ambrose, bishop of Milan, and introduced by him into the churches of his diocese. As to what it amounted to precisely considerable doubt exists, but it is generally agreed that St. Ambrose transplanted the singing of the Hallelujah and antiphonal singing from Greece into Italy, while he is also looked upon as the originator of the Responses. Otherwise the Ambrosian Chant seems to have had much in common with the Gregorian, which is regarded by some as having been merely a comprehensive revision of the then existing (7th century) ritual song, based on Ambrosian practice, although doubtless including much which had been added after St. Ambrose's death (397). St. Ambrose was also responsible for the introduction of hymn-singing, as distinguished from the chanting of the Psalms and the canticles, as an essential feature of the music of public worship in the Western Church, and wrote many hymns himself, though the number of genuine examples to be ascribed to him is less than has sometimes been stated. (See also **AMBROSE**, **SAINT**; **GREGORY** [Pope]; and **PLAIN-SONG**.)

AMBROSIA, the name given to several religious brotherhoods which at various times since the 14th century have sprung up in and around Milan; they have about as much connection with St. Ambrose as the "Jeromites" who were found chiefly in upper Italy and Spain have with their patron saint. Only the oldest of them, the *Fratres S. Ambrosii ad Nemos*, had anything more than a very local significance. This order is known from a bull of Gregory XI. addressed to the monks of the church of St. Ambrose outside Milan. These monks, it would appear, though under the authority of a prior, had no rule. Their discipline became so slack that an appeal was made to Cardinal Borromeo asking him to reform their houses. By Sixtus V. the order was amalgamated with the congregation of St. Barnabas, but Innocent X. dissolved it in 1650.

The name Ambrosians is also given to a 16th century Anabaptist sect, which laid claim to immediate communication with God through the Holy Ghost. Basing their theology upon the words of the Gospel of St. John i. 9 ("There was the true light which lighteth every man coming into the world"), they denied the necessity of any priests or ministers to interpret the Bible. The doctrine of the Ambrosians may be compared with the "inner light" doctrine of the Quakers.

See Herzog-Hauck's *Realencyklopädie*, i. 439.

AMBROSIAS. A commentary on St. Paul's epistles, "brief in words but weighty in matter," and valuable for the criticism of the Latin text of the New Testament, was long attributed to St. Ambrose. Erasmus in 1527 threw doubt on the accuracy of this ascription, and the author is usually spoken of as Ambrosiaster or pseudo-Ambrose. Owing to the fact that Augustine cites some parts of the commentary on Romans as by "Sanctus Hilarius" it has been ascribed by various critics at different times to almost every known Hilary.

See Souter, *Study of Ambrosiaster* (1905), with references given there.

AMBROSIO AURELIANUS, leader of the Britons against the Saxons in the 5th century, was, according to the legends preserved in Gildas and the *Historia Brittonum*, of Roman extraction. There are signs of the existence of two parties in the national opposition to the invaders, but as Pascent, son of Vortigern, is said by Nennius to have held his dominions in the west by leave of Ambrosius, the Roman element seems to have triumphed. It has been suggested that Amesbury in Wiltshire is connected with Emrys, the Celtic form of his name.

See Bede, *Ecl. Hist.* (Plummer) i. 16; Nennius, *Hist. Britt.* § 31; Gildas, *De excidio Britanniarum*, § 25; J. Rhys, *Celtic Britain* (1884), pp. 104, 105, 107.

AMBRY. An ambry in mediaeval churches was a wall-niche or recess near the altar in which the sacred vessels were kept. Large churches and cathedrals had numerous ambries fitted with shelves and richly carved doors, where consecrated oils, vestments, holy relics, books or linen were stored. Occasionally an ambry was a chest or cupboard hung near the altar. Variant forms of the word are almy, aumbry and armalorium.

AMBULANCE, a term applied in England and America to the wagon or other vehicle in which the wounded in battle, or those who have sustained injuries in civil life, are conveyed to hospital. More strictly it signifies a hospital establishment moving with an army in the field, to provide for the collection, treatment and care of the wounded on the battlefield, and of the sick, until they can be removed to hospitals of a more stationary character. In 1905-06 the term "field ambulance" was adopted in the British service to denote this organization. The description of the British service given below applies to the system in vogue in the army after the experience gained in the World War.

The ambulance organization which, variously modified in details, now prevails in all civilized armies, only dates from the last decade of the 18th century. Hitherto surgical assistance did not reach the battlefield till the day after the engagement, or even later. In 1792 Baron Dominique Jean Larrey (1766-1842) of the French army introduced his system of *ambulances volantes*, or flying field hospitals, like the "flying artillery" of that time. They were adapted both for giving the necessary primary surgical treatment and for removing the wounded quickly from the sphere of fighting. A corps of *brancardiers*, or stretcher-bearers, was organized about the same time.

Geneva Convention.—An important step towards the amelioration of the condition of the wounded of armies in the field was the European convention signed at Geneva in 1864, by the terms of which, subject to certain regulations, the wounded and the official staff of ambulances and their equipment were declared neutral.

The American Civil War marked the beginning of the modern ambulance system. The main feature of the hospital organization throughout that war was the railway hospital service. Hospital trains and ships equipped with medical staff, nurses, stores and appliances, for the transport of cases from the front to the base, were rapidly introduced into other armies.

In the Japanese army a special feature is the sanitary corps, whose duty is the prevention of disease among the troops; it has been brought to a great pitch of perfection, with the result that in the Russo-Japanese War (1904-05) the immunity of the troops from all forms of preventable disease surpassed all previous experience. Not only was the army accompanied by sanitary experts who advised on all questions of camping grounds, water supply, etc., but before the war began the Intelligence Department collected information as to the diseases of the country likely to be the scene of operations, unhealthy places to be avoided, etc.

British Army System.—Coming now to the ambulance system of the British army, we shall trace the progress of a wounded man from the field of battle to his home.

When a soldier is wounded the regimental surgeon and stretcher-bearers apply the "first field dressing"—a packet of antiseptic material which every officer and man on active service carries stitched to his tunic. From the field he walks or is carried on a stretcher by bearers of the Royal Army Medical Corps to the collecting station, where he is placed on an ambulance wagon and taken to the dressing station. Here his wound is examined if necessary, but as on the field the first medical officer who examined him has already attached a "specification tally" to the patient, giving particulars of the wound, it will probably not be disturbed. Any urgent operation, however, will be here performed, nourishment, stimulants and opiates administered if required, and the patient moved to the field hospital in an ambulance wagon. From the field hospital he is transferred as soon as possible by ambulance train to the general hospital at the advanced base of operations,

and from there, by one or more stages, he is ultimately either returned to duty or sent home in a hospital ship. In warfare in hilly or uncivilized countries special arrangements for transport of the wounded are adopted. The Indian Medical Service is self-contained, and by reason of caste restrictions special modifications have been introduced, but the general arrangements resemble those of the Home army.

Different regulations are made by various powers as to the work of the Red Cross societies under the Geneva flag (*see* RED CROSS). Whereas in Germany and France such aid is officially recognized and placed under direct military control, the English Red Cross societies have acted side by side with, but independently of, the military ambulance organization.

St. John Ambulance Association.—Great attention has been paid to civil ambulance organization in England. In 1878 the British ambulance association of St. John of Jerusalem was founded. Its object was to render first aid to persons injured in accidents on the road, railway or in any of the occupations of civil life. As the result of the initiative taken by this association, ambulance corps have been formed in most large towns of Great Britain; and police, railway servants and workmen have been instructed how to render first aid pending the arrival of a doctor. The Association, whose headquarters are in Clerkenwell, London, has branches in most parts of the British empire.

Ambulance Wagons.—British ambulance wagons are built to convey four patients lying down, one seated, and the driver, or fourteen persons all seated. The Indian ambulances are small two-wheeled carts drawn by two bullocks or mules; very strongly made, they are capable of holding two men lying down or four sitting up, besides the native driver.

AMBULATORY, the covered passage round a cloister, or the aisle or procession way around the east end of a church choir behind the altar.

AMBUSCADE, an alternative form of ambush (*q.v.*).

AMBUSH (older form, "embush," O.Fr. *embusche*, from the Ital. *imboscata*, in and *bosco*, a wood), the hiding of troops, primarily in a wood, and so any concealment for the purpose of a sudden surprise attack.

AMEBLASIS or AMOEBIASIS: *see* PARASITIC DISEASES.

AMEDEO FERDINANDO MARIA DI SAVOIA, DUKE OF AOSTA (1845–90), third son of Victor Emmanuel II., king of Italy, and of Adelaide, archduchess of Austria, was born at Turin May 30 1845. In 1868 he was created vice-admiral of the Italian Navy, but two years later left Italy to ascend the Spanish throne, his reluctance to accept the invitation of the Cortes having been overridden by the Italian cabinet. On Nov. 16 1870 he was proclaimed king of Spain by the Cortes; but before he could arrive at Madrid Marshal Prim, chief promoter of his candidature, was assassinated.

Though warned of a plot against his life (Aug. 18 1872) he refused to take precautions, and while returning from Buen Retiro to Madrid in company with the queen was repeatedly shot at in the Via Arenal, but escaped unhurt. A period of calm followed the outrage. On Feb. 11 1873, however, Amedeo, abandoned by his partisans and attacked more fiercely than ever by his opponents, signed his abdication. Upon returning to Italy he was cordially welcomed and reinstated in his former position. His wife, born Princess Maria Carlotta del Pozzo della Cisterna, died Nov. 3 1876. On Sept. 11 1888, Amedeo contracted a second marriage with his niece Princess Letitia Bonaparte. Less than two years later (Jan. 18 1890) he died at Turin, leaving four children—the duke of Aosta, the count of Turin, the duke of the Abruzzi (issue of his first marriage), and the count of Salemi.

AMELIE-LES-BAINS, watering place, south-west France, in the department of Pyrénées-Orientales, at the junction of the Mondony with the Tech. 28½m. south-south-west of Perpignan by rail. Pop. (1926) 1,484. It has numerous warm sulphurous springs and both a winter and summer season. There are two bathing establishments, one of which preserves remains of Roman baths. The town was known successively as Arles-les-Bains, Bains-sur-Tech and Fort-les-Bains, and received its present name in 1840 in honour of the wife of Louis-Philippe.

AMELOT DE LA HOUSSAYE, ABRAHAM NICOLAS (1634–1706), French historian and publicist, was born at Orleans in Feb. 1634 and died in Paris on Dec. 8, 1706. His most important work is *Histoire du gouvernement de Venise* (1676), which called forth a violent protest from the Venetian ambassador in Paris. The author spent six weeks in the Bastille, but the popularity of the book was increased by the publicity given to the affair. It went through 22 editions in three years, and was translated into English and other languages.

AMEN. This old Hebrew expression has become "perhaps the most widely known word in human speech," being used today in worship not only by Jews but by Christians and, in a minor degree, by Mohammedans. (a) As a religious term expressing affirmation and desire it signifies (as in the Greek translation of the O.T.) "so be it"; (b) but essentially it was an interjection of *assent*—"so it is," or "so it will be," even of secular application (1 Ki. i., 36; Jer. xi., 4, xxviii., 6) in the sense of "yes." The Hebrew verb means *to be firm, or sure; also to be trusted.* (1) The term is employed by the user to adopt as his own, words spoken by another; so in Tobit viii., 8; cf. Judith xiii., 20. As a response of the people at the close of a doxology or prayer uttered by the priest, it is found in Neh. viii., 6; 1 Chron. xvi., 36; cf. Ps. cvi., 48. This use, which became especially common in the Jewish synagogue, was developed by the Christian church. In 1 Cor. xiv., 16, St. Paul refers to "the Amen." Justin c. 150 A.D. writes: "The president likewise offers up prayers and thanksgivings, and the people answer the Amen" (*Apol.* I. 67; cf. 65). (2) Developed out of this use Amen is employed also by the *offerer* of thanksgivings and prayers, public and private, in order to sum up and thus to confirm what he himself has said. Signs of this use even in the O.T. are to be seen in the detached doxology placed as vv. 18 and 19 of Ps. lxxii., and in the short doxologies with which the 3rd and 4th books of Maccabees end. It is found in Rom. i., 25; Gal. vi., 18, etc., and it has become exceedingly common with Christians. Like (1), as an aid in focusing the concentration of the worshipper, its value is obvious. With the growing popularity of hymns the use of Amen has been extended. (3) Unique, but in harmony with the meaning "so it will be," was the usage of Jesus Christ to *introduce* a statement of his own by "Amen" (translated "Verily"), "I say unto you" (or "thee"). In the Fourth Gospel uniformly, and only in that gospel, is the *double* and more emphatic "Verily, verily" (*e.g.*, iii. 3); cf. the double Amen in Ps. xli., 13, etc. In Rev. iii., 14, the word Amen is applied, probably under the influence of Isa. lxxv., 16, to Christ Himself; *i.e.*, He in whom things become true—"the faithful and true witness"; cf. 2 Cor. i., 20. The nearest parallel to the Amen introducing a sentence is in Rev. i., 7, where the writer *closes* an affirmation thus: "Behold he cometh . . . Even so, Amen."

See Hogg, *Jew. Qrly. Rev.*, Oct., 1896; Nestle, *Exp. Times*, 1897 pp., 190ff.; Dalman, *Worte Jesu* pp. 185–187 (Eng. trans. pp. 226–229). (R. S. C.)

AMENDMENT, an improvement, correction or alteration (nominally at least) for the better. The word is used either of moral character or, more especially, in connection with "amending" a bill or motion in parliament or resolution at a meeting; and in law it signifies the correction of any defect in the record of a civil action or on a criminal indictment.

(*See also* AMERICAN LAW.)

AMENDOLA, GIOVANNI (1882–1926), Italian politician and journalist, was born at Naples, April 15 1882. He entered journalism at the age of 18, and eventually became Rome correspondent of the Milan *Corriere della Sera*, which he left in 1921 to found a paper of his own, *Il Mondo*. In 1919 he was elected deputy for Sarno in the province of Salerno and re-elected in 1921 and 1924. After the World War he devoted himself entirely to politics as a Democratic Liberal and a supporter of Nitti. On Nitti's fall, June 9 1920, he joined the opposition to Giolitti, and became minister for the colonies, first under Bonomi, then under Facta. He opposed Fascism from the first, and after Mussolini's advent to power he became in some sense the leader of the heterogeneous opposition groups. After the Matteotti crime he was the leader of those who withdrew from the Chamber to the Aventine

(see ITALY). His devotion to constitutional principles led him during the election campaign of 1924 to declare the electoral law enacted by the Fascist Government to be unconstitutional and therefore null and void. His two publications *Una battaglia liberale* (1924) and *La Democrazia dopo il 16 Aprile 1924* (1924) made known his political faith. His death in hospital at Cannes, April 6 1926, was thought to be the result of the two attacks on his life on Dec. 26 1923, in Rome, and in Aug. 1925, while on holiday at Montecatini.

AMENEMHET I., the ruler of Egypt who began the 12th Dynasty (c. 2212 B.C.²). His personal name was Sehetepibre, which shows that he was especially devoted to Amon (*q.v.*), the god of Epet. (See *Cambridge Ancient History*, vol. i. 2nd ed., 1924.)

AMEN HOTEPI, I.-IV.: see EGYPT, *The New Empire*.

AMENORRHOEA is the absence of menstruation between the age of puberty and the menopause. In those who have never menstruated the cause of amenorrhoea is usually poor general health or anaemia. Occasionally it is found to be an abnormality in the development of the genital tract, and it has also been ascribed to glandular unbalance. Often no cause can be found. After the onset of menstruation by far the most common cause of missing a period is pregnancy. During acute diseases the period may be delayed or missed, and in the course of chronic debilitating diseases menstruation is often suppressed. Operative removal of uterus and ovaries, and certain diseases of the ovaries, also cause amenorrhoea. Strong emotions, especially the dread of pregnancy, may likewise account for it. Amenorrhoea in itself is not serious, but the condition causing it may require investigation and treatment.

AMEN-RE: see EGYPT, *Religion*.

AMENTACEAE or **AMENTIFERAE**. This name was formerly used to include the families of plants which bear their flowers in catkins (*amenta*). It comprised the families *Salicaceae*, willows and poplars, *Juglandaceae*, walnut and hickory, *Betulaceae*, birch and alder, *Fagaceae*, oak, beech and chestnut. It is not used in the most modern systems of botanical classification.

AMERCEMENT or **AMERCIAMENT**, in English law, an arbitrary pecuniary penalty, inflicted in old days on an offender by the peers or equals of the party amerced. The word has in modern times become practically a poetical synonym for fine or deprivation. But an amercement differed from a fixed fine, prescribed by statute, by reason of its arbitrary nature; it represented a commutation of a sentence of forfeiture of goods, while a fine was originally a composition agreed upon between the judge and the prisoner to avoid imprisonment. The assessment of an amercement was termed an *affeerment*. In the lower courts the amercement was offered by a jury of the offender's neighbours (*affeerors*); in the superior courts by the coroner, except in the case of officers of the court, when the amount was affeered by the judges themselves. All judgments were entered on the court roll as "in mercy" (*sit in misericordia*). Articles 20 to 22 of Magna Charta regulated the assessment of amercements.

See Stephen, *Hist. Crim. Law*; Pollock and Maitland, *Hist. Eng. Law*; McKechnie, *Magna Carta*.

AMERIA (mod. AMELIA), Umbria, about 65m. N. of Rome on the Via Amerina (which diverged from the Via Cassia, passing through Castellum Amerinum, probably mod. Orte, where it crossed the Tiber). It has a fine position, 1,332ft. above sea-level, and still retains considerable remains of the city wall with jointed polygonal blocks of limestone. Roman remains include a large ten-chambered water reservoir. The lofty campanile of the cathedral was erected in 1050. Ameria is alluded to as a flourishing place, with a fertile territory extending to the Tiber, by Cicero in his speech in defence of Sextus Roscius Amerinus.

AMERICA, the general name by which the huge continent called the western hemisphere is now known. It is commonly agreed that the name is derived from that of the navigator, Amerigo Vespucci (*q.v.*). America is divided geographically and ethnologically into three parts: North America (Canada and the United States of America); Central America and South America. These three divisions will be found treated separately under their own names.

Physical Geography.—The accidental use of a single name, America, for the pair of continents that together have a greater north-south extension than any other continuous land area of the earth, gives some support to the theory of its tetrahedral deformation; for America, broadening in the north toward its neighbours on the east and west, and tapering far to the south toward the Antarctic continent, roughly presents the triangular outline that is to be expected from tetrahedral warping. There is, however, not a unity but a duality, in its plan; North and South America resemble each other roughly in geological evolution as well as in outline, their chief correspondences being: (1) the area of ancient fundamental rocks in the north-east (Laurentian highlands, Guiana), without great deformation since early geological times; (2) the area of south-eastern highlands (Appalachians, Brazil), with a crystalline belt near the ocean and more or less deformed Palaeozoic strata farther inland, both owing their present altitude to broad and modern geological uplifts; (3) the complex of younger mountains along the western coasts (Cordilleran highlands of both continents) of comparatively modern deformation and upheaval, associated with much volcanic activity; (4) confluent lower lands between the several highlands, with rivers flowing to the north (Mackenzie, Orinoco), east (St. Lawrence, Amazon), and south (Mississippi, La Plata). Differences are numerous, but they do not suffice to conceal the resemblance in general plan. Indeed, the chief differences between the two continents arise from their unlike position with respect to the equator. North America is bathed in frigid waters around its broad northern shores, its mountains in the north-west bear huge glaciers, the outlying north-eastern area of Greenland is shrouded with ice, and in geologically recent times a vast ice-sheet spread over its north-eastern third; while a warm and moist climate in its southern part gives it a torrid flora and fauna, and warm waters bring coral reefs to parts of its southern shores. South America has a torrid flora and fauna over its northern half and coral reefs on parts of its northern shores, while cold waters and glaciers characterize its narrowing southern end, where geologically recent glaciation has taken place.

The similarity of outline between the western margin of the Old World and the eastern margin of the Americas, long ago noticed, has in recent years been taken to support a daring theory of continental fragmentation, according to which the Atlantic is thought to occupy the space left vacant when America floated away westward from its original moorings.

The relation of the Americas to the rest of the world as the home of plants and animals is greatly affected by the breadth of the adjacent oceans. Between the parallels of 60° and 70°N., the east-and-west widening of North America forms more than a third of the almost continuous land ring around a zone of sub-Arctic climate; as a result there is a remarkable resemblance of plant and animal life in the high latitudes of North America and Eurasia. In strong contrast with this is the exceptional isolation of far southern South America, which but slightly interrupts a sub-Antarctic ocean ring; as a result, the land flora and fauna of South America to-day are strongly unlike those of the other south-ending continents.

For further treatment of the physical geography of the American continents, see NORTH AMERICA and SOUTH AMERICA. (W. M. D.)

GENERAL HISTORICAL SKETCH

The name America was derived from that of Amerigo Vespucci (*q.v.*). In Waldseemüller's map of 1507 the name is given to a body of land roughly corresponding to the continent of South America. As discovery revealed the existence of another vast domain to the north, the name spread to the whole of the pair of continents, in spite of the protests of the Spaniards, by whom it was not officially used of North America till the 18th century.

Barring any trips which the Norse sea-rovers made, or may have made, to the Western continent, the discovery of America is justly dated, Oct. 12 (N.S. 21) 1492, when Christopher Columbus (*q.v.*), the Genoese, made his landfall on the island of Guanahani, now identified with Watling island in the Bahamas. After many disappointments Columbus persuaded the catholic sovereigns, Ferdi-

nand and Isabella of Spain, to furnish him with a squadron of three small vessels. With it he sailed from Palos in Andalusia on Aug. 3, 1492, reached Guanahani on Oct. 12, touched on the coast of Cuba and on Hispaniola, established a small post, and returned to Lisbon on March 4, 1493, and thence to Spain.

It was the belief of Columbus and his contemporaries that he had reached the islands described by Marco Polo as forming the

FROM WALDSEEMÜLLER, "COSMOGRAPHIÆ INTRODUCTIO," ST. DIE, MAY 1507

THE EARLIEST MENTION OF AMERICA

In his essay, "Cosmographiæ Introductio," published in 1507, a geographer, Martin Waldseemüller, termed the western lands "America" after Amerigo Vesputio who had referred to them for the first time as the New World in 1499

eastern extremity of Asia. Hence he spoke of the "Indies," and "las Indias" continued to be the official name given to their American possessions by the Spaniards for many generations. His feat produced a diplomatic controversy with Portugal which was destined to have important political consequences. In 1454 Pope Nicholas V. had given the Portuguese the exclusive right of exploration and conquest on the road to the Indies. His bull contemplated only the use of the route by the coast of Africa to the south and east. After the return of Columbus and his supposed demonstration that the Indies could be reached by sailing west, disputes might obviously arise. The catholic sovereigns applied to Pope Alexander VI., a Spaniard, for a confirmation of their rights. The pope drew a line from north to south 100 leagues west of the Azores and Cape Verde islands, and gave the Spaniards the claim to all to the west (May 4, 1493). The Portuguese thought the division unfair to them, and protested. A conference was held between the two powers at Tordesillas in 1494, and by common consent the line was shifted to 370 leagues west of the Cape Verde islands. The boundary line is generally considered as the 50th degree of longitude west of Greenwich, which strikes the mainland of South America about the mouth of the Amazon. Thenceforward the Spaniards claimed the right to exclude all other peoples from trade or settlement "beyond the line."

Between Sept. 1493 and the time of his last voyage (May 1502 to Nov. 1504), Columbus explored the West Indies, reached the mainland of South America at the mouth of the Orinoco and sailed along the coast of Central America from Cape Honduras to Nombre de Dios (near Colon). Henry VII. of England allowed the Bristol merchants to fit out a western voyage under the command of another Genoese, John Cabot (*q.v.*), in 1497. The history of the venture is very obscure, but Cabot is thought to have reached Newfoundland and the mainland. Between 1500 and 1503 a Portuguese family of the name of Cortereal carried out voyages of exploration on the eastern coast of North America. In 1500 the Portuguese, Pedro Álvares Cabral, while on his way to the East Indies, sighted the coast of Brazil at Monte Pascoal in the Aimores, and took formal possession. The belief that the eastern extremity of Asia had been reached died slowly, and the great object of exploration in America continued to be the discovery of a passage through to the Spice islands, in order to compete with the Portuguese, who had reached them by the Cape route. The first Spanish settlement in Hispaniola spread to the mainland by the adventure of Alonso de Ojeda and Diego de Nicuesa in Darien in 1509. Cuba was occupied by Diego de Velasquez in 1511. In 1512 (or 1513) Juan Ponce de Leon made the first recorded exploration of the coast of Florida and the Bahama channel. In 1513 Vasco Nuñez de Balboa crossed the isthmus

of Darien and saw the South Sea (Pacific). The hope that a passage through to the Spice Islands would be found near existing Spanish settlements was now given up. One was sought farther south, and in Nov. 1520 Ferdinand Magellan (*q.v.*) passed through the strait which bears his name and sailed across the Pacific. At last the existence of a continent divided by a vast stretch of ocean from Asia, and mostly lying within the sphere of influence assigned to Spain by the pope, was revealed to the world.

The first aim of the Spaniards had been trade with the Indies. The *Casa de Contratacion*, a committee for the regulation of trade, was established at Seville in 1503. European plants and animals were introduced into Hispaniola and Cuba, and sugar plantations were set up. But the main object of the Spaniards was always gold, to be won by slave labour. As the surface gold of the islands was exhausted, and the feeble island races perished before the invaders, the Spaniards were driven farther afield. In 1519 Pedrarias Davila transferred the Darien settlement to Panama. In that and the following year the coasts of Yucatan and of the Gulf of Mexico were explored successively by Francisco Hernandez Córdova and Juan de Grijalva, who both sailed from Cuba. From Cuba it was that Hernan Cortes (*q.v.*) sailed on Feb. 10 or 18, 1519, for the conquest of Mexico. Hitherto the Spaniards had met only the weak islanders, or the more robust cannibal Caribs, both alike pure savages. In Mexico they found "pueblo" or town Indians who possessed an organized government and had made progress in civilization. The hegemony of the Aztecs, who dominated the other tribes from the central valley of Mexico, was oppressive. Cortes, the most accomplished and statesmanlike of the Spanish conquerors, raised the subject peoples against them. His conquest was effected by 1521. His example stimulated the settlers at Panama, who had heard of a great people owning vast quantities of gold to the south. Between 1524 and 1535 Francisco Pizarro (*q.v.*) and Diego de Almagro had completed the conquest of Peru, which was followed, however, by a long period of strife among the Spaniards, and of rebellions. From Peru the Spaniards advanced southwards to Chile, which was first unsuccessfully invaded (1535-37) by Diego de Almagro. Their advance to the south was checked by the indomitable opposition of the Araucanians, but from the southern Andes the Spaniards overflowed on to the great plains which now form the interior of the Argentine republic. The first permanent settlement at the mouth of the river Plate at Buenos Aires dates from 1580. In its main lines the Spanish conquest was complete by 1550. What the Spaniards had then overrun from Mexico to Chile is still Spanish America. Brazil, after a period of exploration which began in 1510, was gradually settled by the Portuguese. The vast territories acquired by Spain in this brief period were held to be, by virtue of the pope's bull, the peculiar property of the sovereign. In 1509 the Council of the Indies was established, but it did not take its final form till 1524. It consisted of a president, with a board of advisers, who possessed legislative and administrative powers, and who varied in number at different times. The *Casa de Contratacion*, another board regulated the trade. In America the Crown was represented by governors. After the preliminary period of conquest the whole of the Spanish possessions were divided into the two "kingdoms" of New Spain—consisting of Venezuela and the Spanish possessions north of the isthmus—and of New Castile, a title soon changed to Peru, which included the Central American isthmus and all of South America except Venezuela and Brazil. Each was ruled by a viceroy. As the Spanish dominions became more settled, the viceroyalty of Peru was found to be unwieldy. New Granada (which included the present republics of Venezuela, Colombia and Ecuador) was created a viceroyalty in 1718 (soon abolished, but re-created in 1740). A fourth viceroyalty for the river Plate was formed in 1778. Other governments known as captain-generalships were cut out of the viceroyalties at different periods.

The government of Spain administered its dominions from the beginning in the strictest spirit of the "colonial system." The Indies were expected to supply precious metals and raw mate-

rials, and to take all manufactures from the mother country. In order to facilitate the regulation of the trade by the *Casa de Contratacion*, it was concentrated first in Seville, and when the Guadalquivir was found to be becoming too shallow for the growing tonnage of ships, at Cadiz. Merchant vessels were required for their protection to sail in convoy. The convoys or *flotas* sailed in October first to Cartagena in South America, and thence to Nombre de Dios or, in later times, Porto Bello. The yearly fairs at these places received the imports from Europe and the colonial trade of the Pacific coast, first collected at Panama and then carried over the isthmus. From Nombre de Dios or Porto Bello the convoys went to La Vera Cruz for the trade of New Spain, and returned home in July by the Florida straits. One-fifth of the produce of the mines belonged to the Crown. The collection of this bullion was at all times a main object with the Spanish government, and more especially so after the discovery of the great silver deposits of Potosi in Bolivia. Forced labour was required to work them and the natives were driven to the toil.

The Portuguese settlement in Brazil was more purely colonial than the Spanish possessions. Until 1534 little was done to regulate the activity of private adventures. In that year the coast was divided into captaincies, which were united under a single governor-general in 1549. Between 1572 and 1576 there were in Brazil the two governments of Rio de Janeiro and Bahia; but its history is of little importance till the occupation of Portugal by Philip II. drew the country into the wars of the Spanish monarchy.

The claim of the peninsula powers to divide the American continent between them, based as it was on an award given in entire ignorance of the facts, would in no case have been respected. As England was in general alliance with the sovereigns of Spain during the early 16th century, Englishmen turned their attention at first towards the discovery of a route to the Spice islands round the north of Asia. But the rivalry of Francis I. and Charles V. gave France a strong motive for assailing the Spaniards in the New World. King Francis encouraged the ill-recorded and disputed voyages of the Florentine Giovanni da Verrazano in 1524, and the undoubted explorations of Jacques Cartier. Between 1534 and 1542 this seaman, a native of St. Malo, explored the Strait of Belle Isle and the Gulf of St. Law-

the dissensions of the colonists. Meanwhile, French corsairs from St. Malo and Dieppe had been active in infesting the West Indies and the trade route followed by the Spanish convoys. After the accession of Queen Elizabeth, and the beginning of the breach between England and Spain, they were joined by English sea-rovers. The English claimed the right to trade with all Spanish possessions in or out of Europe by virtue of their

THE "MAYFLOWER"

In 1620, 35 years after the Raleigh expeditions, and 118 years after Columbus landed at San Salvador, a party of pilgrims sailed from Southampton on the "Mayflower" for the New World. A voyage of 65 days brought them to the shores of North America, and they settled at Plymouth. A treaty of trade and amity made in the reign of Charles V. The Spaniards maintained that there was "no peace beyond the line," i.e., Pope Alexander's line as finally fixed by the conference at Tordesillas. The English retaliated by armed smuggling voyages.

It was, however, not till late that they attempted to found permanent settlements. In 1578 Sir Humphrey Gilbert obtained a patent for discovery and settlement. In 1583 he perished in an effort to establish a colony in Newfoundland. His work was taken up by his half-brother, Sir Walter Raleigh, in 1584. Between 1586 and 1603 Sir Walter made successive efforts to settle a colony in the extensive territory called Virginia, in honour of Queen Elizabeth. His colony at Roanoke, in what is now North Carolina, was unsuccessful, and after his fall his patent reverted to the Crown, but the new Virginia company carried on his schemes. In 1607 the first lasting settlement was made in Virginia, and after a struggle began to flourish by the cultivation of tobacco.

In 1620 another settlement was made. A small body of religious dissentients, 101 men, women, and children, secured leave from the Virginia company to plant themselves within its bounds. They sailed in a single ship, the "Mayflower," and landed near Cape Cod, where they founded the colony of Plymouth, afterwards (1621) obtaining a patent from the council for New England. From these two centres, and from later settlements, arose the "plantations" of the English, which gradually increased to the number of 13 and were destined to become the United States of America.

The English colonies, though divided by interest or character, were all alike jealous to defend, and eager to extend, their freedom of self-government, based on charters granted by the Crown. The settlers by degrees threw off the control of the proprietors who had received grants from the Crown and had promoted the first settlements. It was a marked characteristic of the English colonists, and a strong element in their prosperity, that they were hospitable in welcoming men of other races—Germans from the Palatinate, and French Huguenots driven out by persecution who brought with them some capital, more intelligence, and enduring hatred of Roman Catholic France. Though the British Government gave, more or less unwillingly, a large measure of self-government to the plantations, it was no less intent than the Spanish Crown on retaining the whole colonial trade in British hands, and on excluding foreigners. Two foreign settlements within the English sphere—the Dutch colony

FROM A MURAL PAINTING BY CHARLES Y. TURNER IN THE HOTEL RALEIGH, WASHINGTON, D.C. THE DEPARTURE OF RALEIGH'S COLONISTS FROM ENGLAND IN 1585 Sir Walter Raleigh sent a group of colonists to Virginia in the hope of establishing a permanent settlement. But the new land offered so many hardships that the colonists sailed home with Sir Francis Drake the following year, just before a relief ship arrived at Roanoke Island in search of them.

rence, and visited the Indian village of Hochelaga, now Montreal. The claims of France to the possession of a great part of the northern half of America were based on the voyages of Verrazano and Cartier. The death of King Francis, and the beginning of the wars of religion, suspended colonial enterprise under royal direction. But the Huguenots, under the inspiration of Coligny, made three attempts to found colonies to the south—at Rio de Janeiro (1555-67), near the present Beaufort, South Carolina (1562), and in Florida (1565). These ventures were ruined partly by the hostility of the Spaniards and Portuguese, partly by

of New Netherland, now New York, and the Swedish settlement on the Delaware—were absorbed by the growing English element.

While the English plantations were striking root along the coast, by somewhat prosaic but fruitful industry, and were growing in population with rapid strides, two other movements were in progress. To the south, the English, French, and Dutch, though often in rivalry with one another, combined to break in on the monopoly of the Spaniards. They turned the maxim that "there is no peace beyond the line" against its inventors. They invaded the West Indies, seized one island after another, and formed the freebooting communities known as the brethren of the coast and the buccaneers. After the renewal of the war between Spain and Holland in 1621, the Dutch invaded the Portuguese colony of Brazil and seized Bahia. A long period of struggle followed, but, after the declaration of Portuguese independence in 1640, local opposition, and the support given to the Portuguese by the French, led to the retreat of the Dutch.

To the north, to the west, and to the south of the English settlements on the mainland, a most characteristic French colonial policy was being carried out. No sooner were the wars of religion over than the French again set about making good their claim to Canada, and to whatever they could represent as arising naturally out of Canada. In 1599, under the encouragement of Henry IV., speculators began to frequent the St. Lawrence in pursuit of the fur trade. Their settlements were mainly trading posts. Their colonists were not farmers but trappers, wood-rangers, *coureurs du bois*, who married Indian women, and formed a mixed race known as the *bois brûlés*. Not a few of the leaders, notably Samuel de Champlain (*q.v.*), who founded Quebec in 1608, were brave, ingenious men, but the population provided no basis for a lasting colony. It was adventurous, small, scattered, and unstable. The religious impulse which was so strong both in the Spanish and the English colonies was prominent in the French, but in the most fatal form. Pious people were eager to bring about the conversion of the Indians, and were zealously served by missionaries. The Jesuits, whose first appearance in New France dates from 1611, were active and devoted. Their aim was to reduce the fierce Red men to a state of childlike docility to priests. It was true that the most active French colonial element, the trappers, were barbarized by the natives, and that the pursuit of the fur trade and other causes had brought the French into sharp collision with the most formidable of the native races, the confederation known as the Five (later Six) Nations. During the reign of Louis XIV., after 1660, the French government paid great attention to Canada, but not in a way capable of leading to the formation of a colony. The king was as intent as the rulers of Spain had been to keep the American possessions free from all taint of heresy. Therefore he carried on the policy of excluding the Huguenots—the only colonizing element among his subjects—and drove them into the English plantations. A small handful of obedient peasants formed the basis of the colony. On this narrow foundation was raised a vast superstructure, ecclesiastical, administrative, and military. His priests, and his officials civil and military, gave the French king many daring explorers. While the English colonies were slowly digging their way, taking firm hold of the soil, and growing in numbers, from the sea to the Alleghanies, French missionaries and explorers had ranged far and wide. In 1682 Robert Cavelier, Sieur de la Salle, who had already explored the Ohio, sailed down the Mississippi and took possession of the region at the mouth by the name of Louisiana.

The problem which was to be settled by a century of strife was now posed. On the one hand were the English plantations, populated, cultivated, profitable, stretching along the east coast of North America; on the other were the Canadian settlements, poverty-stricken, empty, over-officialled, a cause of constant expense to the home government, and, at a vast distance, those of Louisiana, struggling and bankrupt. The French remedy for an unsuccessful colony had always been to annex more territory, and forestall a possible rival. Therefore the French government strove to unite the beggarly settlements in Canada and Louisiana by setting up posts all along the Ohio and the Mississippi, in

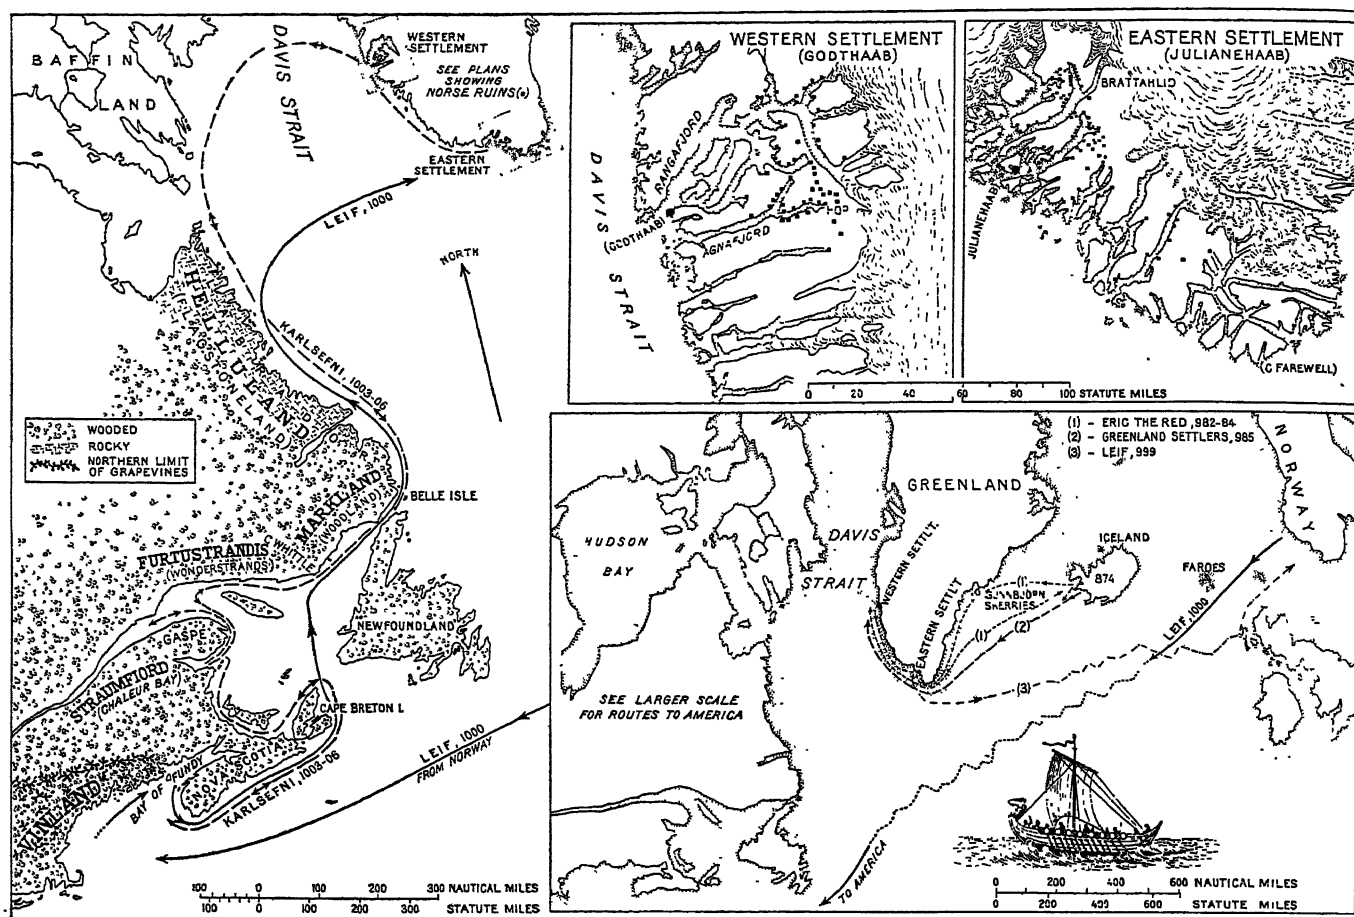

order to confine the English between the Alleghanies and the sea.

The political history of North America till 1763 is mainly the story of the pressure of the English colonies on this paper barrier. As regards Spanish America, England was content to profit by the *Asiento* treaty, which gave her the monopoly of slave-hunting for the Spanish colonies and an opening for contraband trade. In the River Plate region, where the dissensions of Spaniards and Portuguese afforded another opening, English traders smuggled. The Spaniards, with monstrous fatuity, refused to make use of the superb waterways provided by the Paraná and Paraguay, and endeavoured to stifle all trade. England's main struggle was with France. It was prolonged by her entanglement in European disputes and by political causes, by the want of co-operation among the English colonies, and their jealousy of control by the home government. The organization of the French colonies, though industrially ruinous, gave them the command of more available military forces than were at the disposal of the English. Thus the fight dragged on. At last, when under the leadership of the elder Pitt (*see* CHATHAM, EARL OF) England set to work resolutely to force a final settlement, the end came. The British navy cut off the French from all help from home, and after a gallant struggle, their dominion in Canada was conquered. They surrendered Louisiana to Spain, which had suffered much in an attempt to help them, and their possessions in America were reduced to their islands in the West Indies and French Guiana.

The fall of the French dominion on the continent of North America was practically the beginning of the existence of independent nations of European origin in the New World. The causes which led to the revolt of the colonies, the political and military history of the war of independence, are dealt with under the heading of UNITED STATES (*History*) and AMERICAN REVOLUTION. The significance of these epoch-making events in the general history of America is that from 1783 onwards there was, in the New World, an autonomous community in entire separation from European control. Such a polity, surrounded as it was by territory dependent on European sovereigns, could not be without a profound influence on its neighbours. Of deliberate direct action there was not much, nor was it needed. The peoples of the 13 States which had secured emancipation from British sovereignty were wisely intent on framing their own Federal Union, and in taking effective possession of the vast territories in the Ohio region and beyond the Mississippi. But their example worked. Their independence tempted, their prosperity stimulated. From the freedom of the United States came the revolt of Spanish America, and the grant by Great Britain to Canada of the amplest rights of self-government.

The effect which the establishment of the great northern republic was bound to have on their own colonies was not unknown to the wiser among the rulers of Spain. They took, however, few and weak steps to counteract the visible peril. The wars of the French Revolution and of Napoleon, in which Spain was entangled, interrupted her communications with her colonies, and weakened her hold on them. The defeat, in 1806 and 1807, of two British expeditions to Buenos Aires and Montevideo, resulting in the capitulation of the English force, gave a great impulse to the self-reliance of the colonists, to whom the credit of the victory entirely belonged. When the intervention of Napoleon in Spain plunged the mother country into anarchy, the colonists began to act for themselves. They were still loyal, but they were no longer passive. The brutality of some Spanish governors on the spot provoked anger. The cortes assembled in Cadiz, being under the influence of the merchants and mob, could make no concessions, and all Spanish America flamed into revolt. For the details of the struggle the reader must refer to the articles ARGENTINA, BOLIVIA, CHILE, COLOMBIA, ECUADOR, PANAMA, PERU, PARAGUAY, URUGUAY, VENEZUELA. Brazil followed the same course in a milder way and a little later. The struggle of Spanish America for independence lasted from 1810 to 1826.

Meanwhile the United States had taken decisive action. President Monroe, in his message to Congress on Dec. 2, 1823, laid

THE CONJECTURAL ROUTES OF THE NORSEMEN TO AMERICA DURING THE VIKING PERIOD, A.D. 800-1000

From the 7th to the 11th century the spirit of expansion that characterized the Norsemen for several hundred years appeared at its height. They settled in France, England, Scotland and Ireland and journeyed as far east as Russia. In the western hemisphere they colonized Iceland and, late in the 10th century, Greenland. It was from this latter place that expeditions were made by Eric the Red and others to the north-east shores of America.

down the rule that no part of America was any longer *res nullius*, or open to colonial settlement. Though the vast ultimate consequences of this sudden appearance of the great western republic in the arena of international politics were not realized even by those in sympathy with Monroe's action, the weight of the United States made any effective protest by the continental powers of Europe impossible. From President Monroe's declaration has grown up what is now known as the Monroe Doctrine (*q.v.*) which, in substance, insists that America forms a separate system apart from Europe, wherein still existing European possessions may be tolerated, but on the understanding that no extension of them, and no establishment of European control over a nominally independent American state, will be allowed.

The Monroe Doctrine is indeed the recognition, rather than the cause, of undeniable fact. Europe is still possessed of some measure of sovereign power in the New World, in Canada, in Guiana, and in the West Indian islands. But Canada is bound only by a voluntary allegiance, Guiana is unimportant, and in the West Indian islands, where the independence of Haiti and the loss of Cuba and Porto Rico by Spain have diminished the European sphere, European dominion is only a survival of the colonial epoch. America, North and South, does form a separate system. Within that system power is divided as it has not been in Europe since the fall of the Roman empire. On the one hand are the United States and Canada. On the other are all the States formed out of the colonial empires of Spain and Portugal. The states of the American Union, as also Canada, are non-tropical, adapted to the development of European races, not mixed with Indian blood, and possessed by long inheritance of the machinery needed for the successful conduct of self-government. They grew during the 19th century in population and wealth at a rate that placed them far ahead of the Spanish and Portuguese states, which in

the beginning were the richer and the more populous. The Spanish and Portuguese states of America are largely tropical, and therefore less adapted to the health of a white race. Their population is divided between a white, an Indian and a coloured portion, the latter two sometimes docile and industrious, sometimes almost savage. They inherited no machinery of self-government. Townships governed by close corporations, and all embedded in the despotic power of the Crown, presented few of the elements out of which a stable commonwealth could be formed. It was inevitable that in the early stages of their history, the so-called Latin communities should fall under the control of "the single person," and no less inevitable that he should be a soldier. The sword and military discipline long supplied the only effective instruments of government. It would have been a miracle if the first generation of Mexican and South American history had not been anarchical. It was not until the last quarter of the 19th century that the greater portion of Spanish and Portuguese America settled down and established permanent and peaceful governments.

In the first quarter of the 20th century this tendency toward political stability was increasingly pronounced. The Spanish-American War, which swept away the last vestiges of Spanish rule in the New World, resulted in certain changes of importance. Following the defeat of Spain, Porto Rico, and later by purchase the Virgin islands, became dependencies of the United States, and Cuba, Haiti, and Santo Domingo came under the influence of the United States. This influence was further strengthened by the acquirement of the Panama Canal Zone and the construction and control of the interoceanic canal, which facilitated American trade and gave the United States overwhelming preponderance in the Caribbean. Moreover, the relations of the United States in co-operation with South American countries in the World War

further established the prestige of the North American republic. Increasing commercial interpenetration fostered economic development and with it a better social and political order. Pan-American conferences, such as that held at Havana in 1928, have in some degree contributed to this result. In this latest period there have been serious lapses on the part of some of the Latin nations. In Mexico the overthrow in 1911 of the efficient government long maintained by Diaz was followed by more than a decade of revolutionary turbulence with repeated usurpations by military leaders. In Brazil the formidable revolt of 1924 seriously disrupted trade in the chief exporting district of the country. Between Chile and Peru the long unsettled Tacna-Arica controversy was revived in 1921 and, despite all efforts to secure arbitration, unsettled for several years the relations of the two countries.

On the whole, however, the Latin nations of America reached during the early decades of the 20th century the highest general level of economic and political stability that they had as yet attained. In this connection it is significant that the strictly Latin peoples in these lands, now that all fear of Spanish political domination has been removed, look to the Latin nations of Europe—to France, Spain, and Italy—for their social, artistic and political ideals and for the basic inspirations of their culture.

BIBLIOGRAPHY.—Separate bibliographies will be found under the headings of the separate States. Amid the plethora of books, the reader cannot do better than consult the *Narrative and Critical History of America*, Justin Winsor (1886-89), in eight large octavo volumes, in which all the chapters are supplied with copious and carefully compiled bibliographies. (X.)

PRE-COLUMBIAN DISCOVERIES

Alleged discoveries of the continent or islands of America by Europeans before Columbus lack foundation, with the exception of those made by the Norsemen. Because of the geographical conditions it was natural that they should be the first to discover territory in the western hemisphere. They advanced step by step towards west and north-west. First they accidentally discovered the Faroes, then Iceland, and finally, early in the 10th century, Gunnbjörn Ulfsson probably sighted the snow-clad mountains of Greenland, when he landed on some desert islands which afterwards were called Gunnbjörn Skerries, and which presumably were identical with some of the islands off Angmagsalik on the east coast. This discovery was not followed up until Eric the Red, who had first been exiled from Norway and thereafter from Iceland, decided to seek those islands in 982 and to ascertain if they were habitable. Thus he discovered the mainland of Greenland, the south-western part of which he explored during the next three years; he thereafter returned to Iceland and succeeded in persuading a number of people to go with him to Greenland, and to establish there a colony on the model of the Icelandic commonwealth.

From this colony further discoveries were made not only along the west coast of Greenland but also on the American continent. These were in the beginning accidental, and a fairly full account of them has been preserved in Icelandic tradition, which has two somewhat different versions of them. The older of the two, the *Saga of Eric the Red*, ascribes the discovery of the continent to Leif Ericson (q.v.); the younger, called the *Tale of the Greenlanders* (found in the *Flatey Book*) makes Bjarni Herjólfsson the first discoverer. The *Saga* is doubtless much more reliable although the *Tale* probably preserved a few touches which the *Saga* left out. The accidental discovery of Leif in the year 1000 was followed up the next year by his brother, Thorstein Ericson, who, however, failed to reach the new lands. Two years later the Icelander, Thorfinn Karlsefni (q.v.), went with three ships from Greenland in search of Vinland with the intention of settling there. His expedition lasted three years (1003-06), at the end of which time he returned to Greenland, realizing that a colony could not be maintained there because of the hostile aborigines.

Probably in 1007, Karlsefni returned to Iceland, where the story of his exploits was finally written down. The various place-names mentioned in this are impossible of definite identification with localities on the American continent, since no genuine Scandinavian remains of those times have been found there. There seems,

however, little doubt that Helluland (Flagstoneland) is Labrador; while Markland (Woodland), the next land south of this, has often been looked upon as identical with Nova Scotia or Newfoundland, but it might as well be sought on the south coast of Labrador, where almost certainly Furdstrandir (Wonderstrands) are to be found. As Prof. Steensby has pointed out, no place on the east coast of America tallies so well with the description of those desolate strands as the low coast west of Cape Whittle. In such case Straumfiord, where Karlsefni wintered twice, has probably to be looked for within the Gulf of St. Lawrence, and Chaleur bay is possibly identical with it. Vinland (q.v.) must, however, be sought somewhere on the coast of New England.

After Karlsefni's expedition Icelandic sources mention only two sailings towards those lands from Greenland; the first of these was in 1121, when Bishop Eric of Greenland left for Vinland, probably as a missionary, but he was never heard of again. In 1347 there arrived in Iceland a ship of Greenland which had been to Markland for timber, but had been driven out of its course. This may indicate that such trips were made now and then from Greenland, although only this one is on record. The Greenland colony probably existed until the 15th century, but at that time its connections with those lands discovered in the west as well as with the mother country had ceased. Although Columbus doubtless visited Iceland some years before his discovery of America, there is no reason to believe that he heard of these early Norse discoveries, or that they in any way influenced him.

Recently an attempt has been made by Dr. Sophus Larsen to show that a combined Danish-Portuguese expedition under Didrik Pining and Pothorst reached the coast of Labrador or Newfoundland shortly after 1472, thus substantiating the alleged discoveries in those regions by the elder Corte Real. The evidence presented in support of this is partly indirect and hence dubious, and partly drawn from late sources which are not authoritative.

For the bibliography of this subject see H. Hermannsson, *Northmen in America 982-c. 1500* (Ithaca, N.Y., 1909). In addition to the titles given under LEIF ERICSON the following may be mentioned: F. Nansen, *In Northern Mists* (1911); W. H. Babcock, *Early Norse Visits to America* (1913); W. Hovgaard, *The Voyages of the Norsemen to America* (1914); H. P. Steensby, *The Norsemen's Route from Greenland to Wineland* (Copenhagen, 1918); H. Hermannsson in *Geograph. Review*, 1927, p. 107 et seq.; G. M. Gathorne-Hardy, *The Norse Discovery of America* (1921); S. Larsen, *The Discovery of North America Twenty Years before Columbus* (Copenhagen, 1924).

(H. HE.)

AMERICA ISLANDS, a name said to have been given to Christmas, Fanning, Palmyra and attendant islets; they have also been called the LINE ISLANDS.

AMERICAN ACADEMY IN ROME, THE, situated on the Janiculum, in Rome, Italy, comprises a School of fine arts and a School of classical studies. It was founded in 1894 under the leadership of Charles F. McKim. It is administered by a director and staff in Rome, and a president and board of trustees in New York city. The School of fine arts includes departments of architecture, painting, sculpture, landscape architecture and musical composition. Seventeen students of advanced attainment are chosen, through annual competitions, as Fellows. The term of the Fellowship in fine arts is three years; in classical studies, one or two years, with residence in the academy and stipend to cover cost of living and travel. There is no formal instruction, but work of certain kinds and travel in classic lands are prescribed. Results of research and reproductions of the work of the artists are published in the *Memoirs or Papers and Monographs* of the Academy. By giving its selected artists and scholars opportunities for intimate association through study and travel in an atmosphere of art and amid the inspiration of masterpieces, the Academy aims to contribute toward the elevation of American art and letters.

AMERICAN AGRICULTURAL CHEMICAL COMPANY, THE, was organized in 1899 under the laws of Connecticut for the purpose of consolidating about 20 companies engaged in the manufacture of fertilizers, in the Northern, Eastern and Middle Western States. The original capital stock of \$20,000,000 preferred, and \$20,000,000 common, has subsequently been increased to a present amount of \$28,455,200 preferred, and

\$33,322,126 common, to provide for the increase in the business. The bonded debt has been reduced from \$36,112,500 in Feb. 1921 to \$12,548,500 on June 1, 1928, and \$2,500,000 additional bonds were called for redemption on Aug. 1, 1928. The company's business has expanded to include the cotton States of the South and the island of Cuba. It early acquired extensive phosphate rock properties and now owns reserves sufficient to supply its needs of this basic material for many decades to come.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, founded in 1848 and incorporated in 1874, is an organization which "aims to advance science in the New World in every feasible way." Its membership was approximately 15,000 in 1927, the majority of the members residing in the United States and Canada. It has two divisions, which are autonomous: the Pacific division and South-western division. In addition to individual membership there are connected with the association 115 wholly autonomous and independent associated organizations, 62 societies and 22 State academies. The association has 15 sections, representing the main current subdivisions of science, each designated by a letter, as follows: A (Mathematics), B (Physics), C (Chemistry), D (Astronomy), E (Geology and Geography), F (Zoological Sciences), G (Botanical Sciences), H (Anthropology), I (Psychology), K (Social and Economic Sciences), L (Historical and Philological Sciences), M (Engineering), N (Medical Sciences), O (Agriculture), Q (Education). Funds are received and administered for the advancement of science and education. The permanent endowment in 1928 amounted to over \$140,000, the income being devoted mainly to grants for scientific research. A volume of summarized proceedings is published at intervals of about four years, including a directory of members. Current expenses are cared for by membership dues. Each member in good standing receives *Science*, the official journal, or the *Scientific Monthly* may be taken instead. The annual meeting occurs during the Christmas holidays, at which time a number of the associated and affiliated societies meet with it for the reading of papers. Its headquarters are at Washington, D.C.

AMERICAN ASSOCIATION OF ADVERTISING AGENCIES, an organization comprised of approximately 140 of the leading advertising agencies in the United States and Canada. For convenience the association is divided into five councils, one for each active business section of the country. The purposes of the association centre around the improvement of advertising and advertising procedure. It has promulgated a standard of ethics for the advertising business which is widely quoted and followed. Correction of such unethical practices as rebating, making false claims in advertising and unfair methods of soliciting business in its field has been one of the important activities of this association. The association maintains a research department which has made a survey of the national field in the study of duplication of periodical circulation. It maintains an export department which operates a rate and data file covering the entire world, primarily in the interests of the manufacturer or advertising agency which advertises in several countries. The association maintains a personnel bureau in which are registered a majority of those actively engaged in national advertising. This is probably the most extensive bureau of its kind in existence. This association also acts as a clearing house for advertising information. While this service is maintained primarily in the interests of the members, it is practically free and open to all who have a legitimate use for the data it has on file.

(H. E. A.)

AMERICAN BANK NOTE COMPANY, THE, an organization in the field of "security" engraving and printing, specializing in quality of workmanship and effective safeguarding during manufacture. In addition to an extensive business in the United States, more than 40 other countries are its customers for bank-notes, postage stamps, revenue stamps, bonds and similar work requiring the protection against counterfeiting given by fine engraving. The business of engraving and printing securities in the United States was founded during the American Revolution by Paul Revere of Boston. His first work of importance was the making of some paper money for the colony of Massachusetts

bay, now the State of Massachusetts. The business was subsequently carried on by various partnerships until 1858 when it was incorporated as the American Bank Note company. In 1879 the National Bank Note company and the Continental Bank Note company were consolidated with it. At various times since the American Bank Note company has acquired the capital stock and property of other concerns. Among these were the Franklin-Lee Bank Note company, Western Bank Note and Engraving company and International Bank Note company. In 1906 the United Bank Note corporation was organized to acquire the stock of the Consolidated American Bank Note company. In 1911 the United Bank Note corporation merged with it and assumed the name American Bank Note company.

At the beginning of 1928 the company's surplus was \$6,299,919; net working capital, \$6,470,266; current assets, \$8,176,784; and total assets, \$19,498,006. The company's principal printing plant is in New York city, with an important branch in Chicago. It has an English subsidiary, Bradbury, Wilkinson and company, Ltd., with a plant at New Malden, Surrey, England, and a Canadian subsidiary, the Canadian Bank Note company, Ltd., with a plant at Ottawa, Canada. Inclusive of its subsidiaries, the company employs a total of some 3,500 persons.

(D. E. W.)

AMERICAN BAR ASSOCIATION, THE, a voluntary association of lawyers and jurists organized at Saratoga, N.Y., in 1878. Its object, as defined by its constitution, is "to advance the science of jurisprudence, promote the administration of justice and uniformity of legislation and of judicial decision throughout the nation, uphold the honour of the profession of the law and encourage cordial intercourse among the members of the American Bar." The association in 1928 had about 28,000 members, residing throughout all of the United States proper and in Hawaii, China, Porto Rico and the Philippine islands. The work of the association is supervised by its president and executive committee. There were in 1928, 15 regular and 10 special committees appointed by the president. In addition to the committees, there were 9 self-perpetuating sections which elected their own officers, while remaining intimately affiliated with the work of the association. Thus, the association, through its committees and the affiliated sections, covers the whole field of the law, including among its activities the adoption of canons of the professional and judicial ethics and advancing the standards of legal education; the introduction and support of measures in Congress for the improvement of the administration of justice; organized opposition to the recall of judges; defence of the power and jurisdiction of the Federal courts; the recommendation of proposed uniform State laws to the legislatures; and the defence of the rights of the poor. The American Bar Association publishes a *Year Book* and an official organ monthly called the *American Bar Association Journal*. Its list of presidents includes the names of lawyers of international reputation, among them being Elihu Root, ex-President Taft, Joseph H. Choate, John W. Davis, Charles E. Hughes, Frank B. Kellogg and other leaders of the bar.

(S. H. S.)

AMERICAN CAN COMPANY, THE, was incorporated in 1901. It was a consolidation of 65 manufacturers of metal containers for foods, chemicals, tobacco, paints and many other products, and is the leading producer in its field. Its manufacturing plants are situated in 45 cities of the United States (18 States), Canada and Hawaii. The company's products include, besides both tin and fibre cans, packages and metal receptacles of many kinds, metal-ware, sheet-metal and other metal manufactures, as well as machinery and tools for all of its activities; also, products and materials originating from such manufactures or found useful in connection with them.

From 1903 to 1927 the plant and real estate account increased from \$77,000,000 to \$116,000,000; the corporate surplus increased \$41,188,772, reaching a total of \$43,851,369 in 1926. Important improvements in buildings and equipment have been made, and new factories have been built as business has increased. In 1927 the company's total current assets were \$50,041,168; total assets, \$167,977,164; net working capital aggregated \$39,118,544; and the capital stock was \$41,233,000, 7% cumulative Preferred (par

\$100), and \$61,849,000, Common (par \$25). Headquarters are in New York city. (H. W. P.H.)

AMERICAN CAR AND FOUNDRY COMPANY, a leading manufacturer in the United States of railway equipment and various allied products. Its incorporation in 1899 effected the union of 13 important manufacturing concerns, situated in eight different States from New York to Missouri, with the avowed purpose of engaging in the manufacture of railway cars and supplies, cast iron pipe and other foundry products. During the period 1899–1928 eight other similar companies, with various subsidiaries, were acquired. When the company was organized, the standard equipment on American railways comprised only wooden passenger coaches, of slight protection to passengers in case of collision, and wooden freight cars limited to a capacity of only 60,000lb. and, owing to the type of construction, to a very short period of service. To the great revolution that has since taken place in the character of railway carriers and equipment, the company has made substantial contributions. Old plants have been modernized and new plants have been built. In 1928 the physical property of the American Car and Foundry Company included 4 passenger car plants, 14 freight car plants, 7 wheel foundries, 8 grey iron foundries, 2 rolling mills and forges, a malleable iron and a brass foundry, an architectural wood-working mill, and a plant for building car floats and small commercial and pleasure boats. Moreover, it controlled subsidiaries equipped for making motor-buses and trucks, electric railway cars, steel dining wagons, gasoline engines, carburetors, and also for welding, steel fabricating and repairing tank cars. The large working capital has been provided from earnings. (W. H. W.)

AMERICAN CIVIL WAR, a conflict lasting four years in the United States of America between eleven States of the South, which asserted their right to leave the Union, and the States and Territories of the North, which were determined to maintain the Union. The Southern States contained slightly over half the population of the Northern States which remained in the Union. At the opening of the conflict, an independent government, the Confederate States of America (*q.v.*) was set up. The Civil War began when the guns of the South fired on the Federal Fort Sumter on April 12, 1861, and ended with the surrender of General Lee at Appomattox on April 9, and of General Johnston at Greensboro on April 26, 1865. Approximately 4,000,000 troops took part in the war, which resulted in the preservation of the Union, the abolition of slavery, and many important social and economic changes.

For the sake of clearness, the names of Confederate statesmen, soldiers and ships are in italics.

Charleston Harbour, 1860–61.—During the last months of Buchanan's presidency a succession of events occurred, which brought the United States to the verge of armed conflict between the rival sections. South Carolina seceded from the Union (Dec. 20, 1860), and Governor *Pickens* sent commissioners to Washington to claim possession of the forts in Charleston harbour and all other U.S. property in his State. Anderson, commanding the Federal garrison, secretly transferred his two weak companies from Ft. Moultrie, which was untenable against a land attack, to Ft. Sumter in the mouth of the harbour (Dec. 26). *Pickens* seized the arsenal and other forts and began throwing up batteries against Sumter, whilst his commissioners at Washington demanded the recall of the Federal troops from Charleston. This demand Buchanan refused. He had already (Dec. 3) in his message to Congress denied the right of secession, though he qualified this denial by expressing the opinion that the Constitution gave him no right to attempt coercion. An unarmed steamer with supplies and reinforcements was sent to the relief of Sumter, but it turned back when fired on as it was entering the harbour (Jan. 9). *Pickens* sent a fresh envoy to demand the surrender of Sumter. Between Jan. 9 and Feb. 1 six other States followed South Carolina's example. Their governors without attempting negotiation seized all the forts and arsenals in their respective States except Ft. Pickens in Pensacola harbour. Delegates from the seceding States met at Montgomery, Ala., organized the Confederate States of America, and set up a pro-

visional Government with *Jefferson Davis* as President. His inauguration took place on Feb. 18. The Confederate Government now assumed control of the negotiations about Sumter. Neither Buchanan nor *Davis* was anxious to precipitate a crisis. The former's fervent desire was to leave the solution of the whole problem to his successor; *Davis* was chiefly concerned to get his administration in working order, whilst Buchanan with a "no

THE FIRST "WHITE HOUSE" OF THE CONFEDERATE STATES, MONTGOMERY. In Dec. 1860, South Carolina seceded from the Union. By Feb. 1861 six other States had followed her example. Their delegates assembled at Montgomery and organized the Confederate States of America, with Jefferson Davis as president. The building now stands near the State Capitol.

coercion" policy was in office, and present the latter's successor with a *fait accompli*. In spite of the remonstrances of *Pickens*, who urged the importance of securing Sumter before Buchanan quitted office, the question was temporarily shelved, though *Beauregard*, an engineer officer of distinction, was sent to Charleston to complete the preparations for attacking Sumter. The day after *Beauregard* reached Charleston, Lincoln was inaugurated at Washington (March 4, 1861).

It was a difficult problem which confronted him. Seven slave States had seceded, but eight still remained in the Union. Any attempt at coercion would throw all these States, except Delaware (which practically counted as a northern State), into the arms of the Confederacy. With these siding with the seceders or even maintaining neutrality as between the two combatants, it seemed impossible to restore the Union by force of arms. At this stage neither side wanted war; certainly not the North, where a strong feeling was growing in favour of letting "the wayward sisters depart in peace"; the South was less reluctant to face the risk, because its leaders were confident that the other slave States would rally to their help, but they were no less confident that, if peace could be maintained, these States would soon seek admission to the Confederacy. Lincoln's inaugural speech was really addressed to the slave States still in the Union; to the Confederate States it sounded like a declaration of war. But they sought to avoid the responsibility of striking the first blow. Theirs was a defensive rôle, that of a newborn nation only asking to be left alone. They hoped to force Lincoln's hand over Sumter. Anderson's position there was daily growing more difficult. The late administration had imposed a policy of inaction. He would himself have gladly evacuated the fort to avert a civil war. But his duty as a soldier compelled him to sit there with folded hands, whilst the enemy were completing their preparations. His provisions would be exhausted by mid-April. The Confederate batteries had made such progress that he doubted whether it was still possible to relieve the fort, unless possession of the whole harbour were secured, and for that purpose he estimated that 20,000 men would be required. The whole U.S. army only numbered 17,000 men, most of whom were scattered in small posts on the Indian frontier, whence they could not be hastily withdrawn. Only on March 5 did Lincoln learn that Anderson might be starved into surrender. Gen. Scott, his chief military adviser, urged evacuation on military grounds. But Lin-

coln had pledged himself "to hold, occupy and possess the property and places belonging to the Government." It would be fatal to the prestige of his administration to start by going back on his word. Evacuation might seem a virtual recognition of the Confederacy. He determined to send food supplies only to Sumter. If the Federal flag was fired on, that would constitute a *casus belli*. The responsibility of beginning the war would be thrust upon the Confederates. To prevent them from pleading a misunderstanding, he gave *Pickens* precise information of his intention. Lincoln must have foreseen the actual event. But only by war could the Union be restored, and the sooner war came, the better; the longer the Confederate Government was allowed to function unchallenged, the more difficult it would become to unite the North in resistance to its "declaration of independence." Lincoln's despatch was delivered to *Pickens* (April 8), who promptly informed his President. From Montgomery orders were sent to *Beauregard* to reduce Sumter. On Anderson's refusal to evacuate, the batteries opened fire at 4:30 A.M. on the 12th. The bombardment continued without intermission till the afternoon of the next day, when Anderson agreed to surrender. At noon of the 14th Anderson evacuated the fort and the Federal flag was lowered. The ready acceptance of Lincoln's challenge by the South was probably due to the desire of its leaders, who now realized his steadfast purpose, to provoke a collision for fear lest the ardour of their people, a considerable minority of whom were originally opposed to secession, might abate. At that date Ft. Sumter and *Pickens* were the only places where they could strike a blow, and they selected the more vulnerable.

The Call to Arms.—The fall of Sumter "set the heather on fire" in the North. Democrats were at one with Republicans in denouncing this crowning insult to the national flag. Lincoln called for 75,000 militia for three months' service (April 15). Not that he underrated his task, but he intended to start by treating secession as an act of insurrection. To suppress insurrection was a constitutional function of the militia, but this force could only be held for three months' service outside its own State. The free States enthusiastically responded to the call, but the governors of the seven slave States still in the Union, except *Hicks* of Maryland, refused to raise their contingents. The Virginia convention passed an ordinance of secession (April 17). Governor *Letcher* immediately seized the Harper's Ferry arsenal and Norfolk navy yard, and without waiting for popular confirmation of the convention's action entered into a military alliance with the Confederacy. North Carolina, Arkansas and Tennessee took the same course. If they had to choose between fighting for and against the Confederacy, they unhesitatingly threw in their lot with their sister States of the South. But Western Virginia beyond the Alleghanies, which had its own personal grievances against the eastern section of the State and belonged geographically to the Ohio valley, repudiated the ordinance of secession and prepared to join the North. In Maryland there was a considerable secessionist minority, chiefly concentrated in Baltimore, where a riot occurred (April 19), as a Massachusetts regiment was passing through to Washington. For three weeks Baltimore was in the hands of the secessionists and the movement threatened to spread through the State. Washington was cut off from direct railway communication with the North. But troops were brought round by water to Annapolis, whence they were railed to the capital. No help came to Baltimore from Virginia, and Governor *Hicks* outmanoeuvred the local leaders of insurrection by pretending to yield to their demands, until *Butler* with a small force made a sudden dash at the city and occupied it unopposed (May 13).

In Kentucky parties were fairly equally divided. There was general sympathy for the South, of which the State regarded itself as a part, but also a genuine devotion to the Union. If the governor favoured secession, a small majority in the legislature was opposed to it. His refusal to supply Lincoln with troops met with no protest from the Unionists, who at first concentrated upon keeping the State neutral. But neutrality could not be a permanent attitude. It gave too great an advantage to the Confederates, who drew food supplies from Kentucky and were

sheltered from invasion along their western front from the Alleghanies to the Mississippi. Sooner or later the Federal armies must occupy Kentucky as a base for an offensive campaign. But a premature movement would drive Kentucky into secession and to lose Kentucky would be "nearly the same as to lose the whole game," in Lincoln's judgment. Understanding the feelings of his fellow Kentuckians better than any of his counsellors at Washington, he handled the critical situation with consummate tact. It was worth suffering some temporary disadvantage to win Kentucky in the end. The legislature steadily refused to summon a convention, which might declare for secession. The governor was too good a Kentuckian to overstep the constitutional limits of his office. In August a new legislature was elected with an overwhelming Unionist majority. The inevitable decision was hastened by the tactless policy of the Confederacy. Kentucky declared for the North (Sept. 20).

In Missouri, Governor *Jackson* was a violent secessionist, eager to go all lengths to take his State out of the Union, and the legislature seemed ready to support him. But the convention, which was summoned, was overwhelmingly Unionist. An extreme section of Unionists, led by F. P. Blair, whose brother was in Lincoln's cabinet, and largely recruited from the Germans in St. Louis, was ready to meet violence with violence. The St. Louis arsenal, the best equipped in all the slave States, was too rich a prize to be allowed to fall into *Jackson's* hands. But in February Scott had placed in it a sufficient Federal force to secure it against sudden surprise, and in March the convention had adjourned without even discussing secession. A large majority of the people favoured neutrality, and a policy of conciliation would probably have preserved peace within the State, as in Kentucky. But Lincoln allowed himself to be guided by the Blairs. Their agent was the fanatical Capt. Lyon, who broke up (May 10) a militia camp close to St. Louis on the ground that *Jackson* was planning an attack on the arsenal, and his return to the city with his prisoners caused a riot with considerable loss of life. This premature appeal to force and the use of Federal troops caused a revulsion of feeling. Civil war became inevitable, when Lyon was appointed temporary commander of the department. He promptly ascended the Missouri with a small force, occupied the State capital, Jefferson City (June 15) and routed a body of secessionist militia at Booneville (June 17). After this defeat *Jackson* fled to the Arkansas border.

Lincoln by undertaking definitely a policy of coercion had lost four more of the slave States, but secured three, and West Virginia was soon to make a fourth.

The Military Outlook.—Twenty-two States (including Kentucky and Missouri) were now arrayed against eleven, and the white population of the former was four times that of the latter. But the 3½ million slaves in the South, so far from being a danger, proved of great assistance, supplying the labour required for the production of food and construction of fortifications. Over two-thirds of the officers and all the men of the U.S. army were on the side of the North; so too was the navy. In material resources and business capacity the North was overwhelmingly superior. All the manufacturing centres were within its borders, all the shipping in its hands. The South was dependent upon it for practically everything except food. But in spite of these advantages the North was likely to find its strength taxed to the uttermost. To restore the Union the South would have to be conquered piecemeal and resistance crushed throughout the whole region, which was "30,000sq.m. larger than the combined areas of Austro-Hungary, Germany, France and Italy, with Belgium, Holland and Denmark thrown in." Neither a few victories in the field nor the capture of the Confederate capital would end the struggle, but only the permanent occupation of great stretches of Southern territory. The country in which the invading armies must operate was sparsely inhabited, with few cities, poor railways and worse roads. Except in a few favoured districts an army could not find subsistence but would have to carry its supplies with it. Consequently it would be tied to its lines of communication; viz., single track railways and rivers. East of the Alleghanies the rivers ran down to the Atlantic across the line of the invader's

advance and constituted formidable obstacles, but to the west the Mississippi, the Tennessee and Cumberland rivers opened a way into the heart of the Confederacy. Their superiority in mechanical resources enabled the Federals to gain command of these rivers with squadrons of gunboats, to which the Confederates could only oppose a few untrustworthy craft. The possession of the navy similarly secured to the North command of the sea. In a war of attrition the blockade would prove a potent weapon. The rôle of the North seeking to reconquer the South was necessarily offensive; that of the South fighting to win its independence mainly defensive. Against such heavy odds the Confederates could not hope to conquer the North, but they expected to make the task of reconquest so costly in life and money that public opinion in the North would demand its abandonment, and in this they nearly succeeded. But at the outset they made a miscalculation. They cherished the delusion that "cotton was king" and that a stoppage of their cotton supply would compel the intervention of Great Britain and France. But in 1861 there happened to be in England, at least, abundant supplies on hand owing to the previous year's record crop, and a glut of manufactured cotton goods. The manufacturers disposing of their accumulated stocks at rising prices had no wish to see the blockade raised. In 1862 and 1863 cotton was exported from Liverpool to New York. The pressure of the "cotton-screw" was not felt till the time for intervention had passed. Yet it was this groundless belief in foreign intervention which dictated *Davis's* military policy in the first stage of the war. He believed that within 12 months at longest, Britain and France would come to his aid, unless he intensified the prejudice felt against the Confederacy as a slave power by wantonly invading the North.

Both sides had to create their armies before they could fight. Here the South had a distinct advantage. The officers who resigned their commissions contained a disproportionately large number of the ablest men in the old army; the two *Johnstons* and *Lee* had been pre-eminent in their profession. *Davis* was a graduate of West Point, had served seven years in the regular army, later as a volunteer won distinction in the Mexican War, had been secretary of war and was chairman of the military committee in the Senate till just before the outbreak of the Civil War. He could be trusted to appoint the best officers to command his armies and to see that the first steps in military organization were wisely taken. Lincoln was void of military experience, had no knowledge of the professional merits of his officers and personal acquaintance with but a few, including McClellan, and no business training. His appointments were too often made for political reasons. Banks, Butler and Frémont were flagrant instances. Again, the Southerners could be more quickly trained as soldiers. There was an aristocracy accustomed to rule, and another class of whites who recognized its claim to their obedience. Under the patriarchal conditions of Southern civilization its men were more robust, accustomed to an open-air life, of pugnacious disposition, trained to the use of gun and horse. The democratic North except in the west, did not provide such good fighting material. The Federal armies were uniformly more successful in the West, where the troops on both sides were much of the same class and the North's superior resources turned the scale, whereas in the East townsmen and European immigrants were fighting against country-bred men. But, given time, the quality of the Northern armies would improve and throughout the advantage of superior numbers would be theirs. But this advantage would be least felt in the first months of the war. The initial problem of both governments was not how to raise men, but how to equip them. There were more volunteers than could be armed. The stocks in the arsenals were quickly exhausted. The South had at least its fair share of them, and *Davis* was purchasing arms in England. But the meagreness of his order (10,000 rifles) indicates that he did not anticipate a lengthy war.

The Opening Moves, April-Aug. 1861.—In the first days Washington, shut in between Virginia and Maryland, had been in danger, but by the end of April was secure against a raid, and a fortnight later railway communication with the North through Baltimore was re-established. *Lee*, commanding the Virginia State

forces, was loath to become the aggressor and refrained from attacking Washington or helping Baltimore. Lincoln had proclaimed a blockade of the Confederate ports (April 19), and called for 42,000 three-year volunteers and 40,000 more men for the regular army and navy (May 3). He was awaiting the result of the referendum to be taken in Virginia on May 23 and scrupulously avoided any violation of Virginian territory. Federal troops crossed the Potomac (May 24) and without opposition occupied the south bank for the protection of the capital.

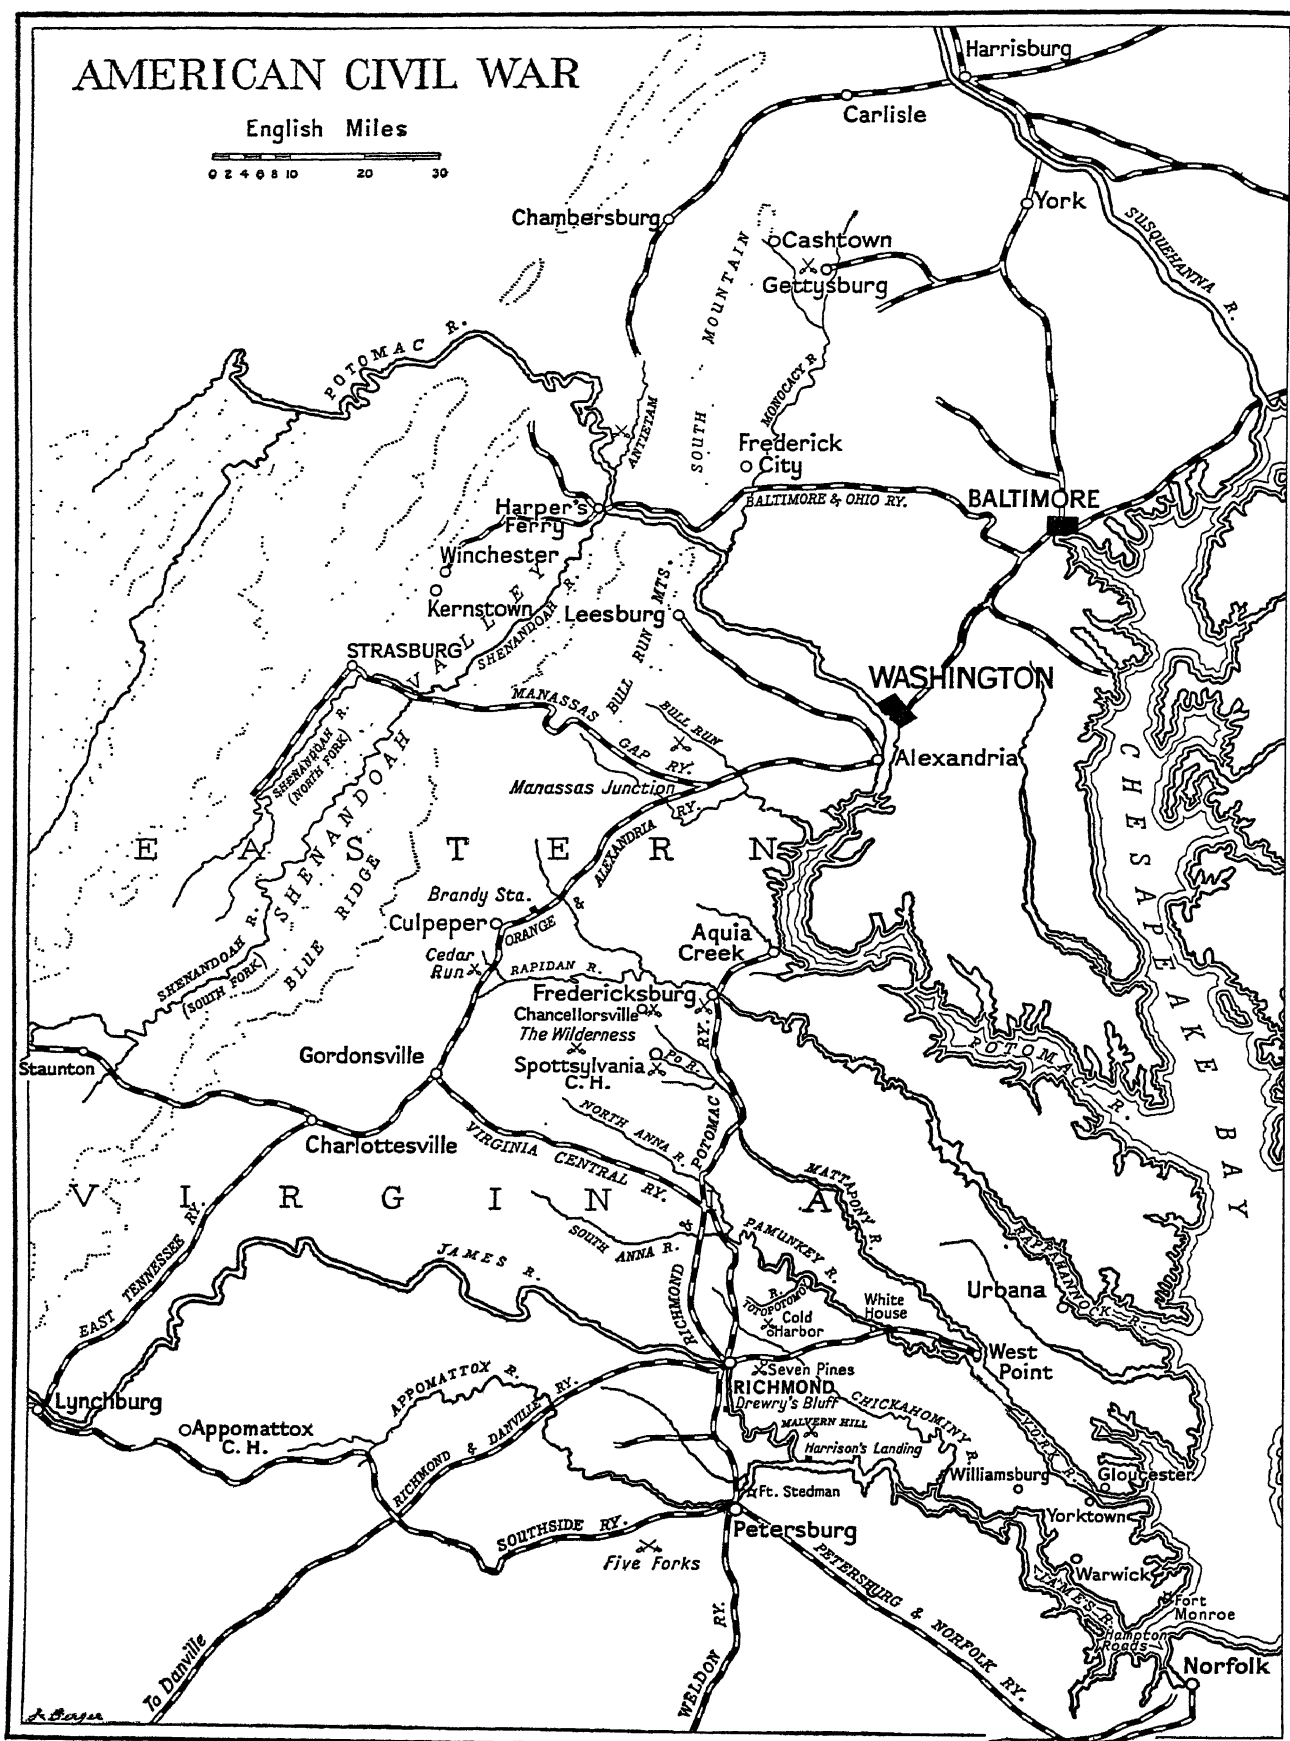

Scott had little faith in the militia. He proposed to use them to defend Washington and recover Harper's Ferry, whilst he trained the volunteers for an autumn campaign. Washington was served by two railways, the Orange and Alexandria (O. and A.) running southward to Lynchburg and the Baltimore and Ohio (B. and O.) passing through Harper's Ferry. The former was joined at Manassas Junction, 30m. from Washington, by the Manassas Gap railway from Strasbourg in the Shenandoah valley. The Valley (as it was commonly called) between the Blue Ridge and the Alleghanies was of great strategical importance, providing the Confederates with a covered line of advance into Maryland and giving them control of a considerable section of the B. and O. railway. To the Federals it was of less offensive value, as its direction led away from Richmond, but its possession would enable them to strike at Richmond's direct line of railway communication with the West.

Lee, now acting as *Davis's* military adviser, was gathering two armies, one under *Beauregard* at Manassas Junction, the other at Harper's Ferry under *J. E. Johnston*. The latter evacuated his post (June 15) when Patterson with a larger force threatened attack, and fell back covering the Manassas Gap railway.

The Richmond authorities had vainly attempted to retain their hold on the western section of the State. Having failed to raise recruits from the district itself for its defence, they sent a small force to hold the crests of the Alleghanies. But McClellan crossed the Ohio and overwhelmed it (July 11-13) at Rich Mountain and Carrick's Ford. Meanwhile a convention at Wheeling had repudiated secession and set up "a Restored Government of Virginia." West Virginia's defection was a serious blow to the Confederates, losing them the Ohio, which they intended to make their line of defence, and the western portion of the B. and O. railway.

At Washington there was a demand that *Beauregard* should be attacked before the term of the militia's service expired. "On to Richmond," the new capital of the Confederacy, was the popular cry. On political grounds a plausible case could be made out for overruling Scott's advice. McDowell, whom Scott, too old and infirm for service in the field, had appointed commander of the forces south of the Potomac, submitted a plan of operations (June 24). With 30,000 men he proposed to drive *Beauregard's* 20,000 back behind the Rappahannock, provided that Patterson prevented *Johnston* from joining him. The Manassas Gap railway gave the Confederates the advantage of "interior lines." McDowell advanced from Alexandria (July 16). The two armies met (July 21) at Bull Run (*q.v.*), where after several hours' fighting the Federals left the field. Their retreat became a panic-stricken flight, which carried them back to the Potomac. The Confederates were too disorganized to conduct an immediate pursuit. Presently they advanced to Centreville, where they established their main position and waited for the Federals to make the next move. Washington quickly recovered from its alarm. McClellan was summoned from West Virginia and started to organize a fresh army. The first pitched battle of the war was barren of decisive results.

In the west a neutral Kentucky interposed a barrier between the combatants, but there was some fierce fighting in south-west Missouri. Lyon pursued *Jackson* as far as Springfield, where he halted to await reinforcements. Ex-Governor *Price*, commanding the State militia, raised a fresh force and being joined by *McCulloch's* troops from Arkansas advanced against Lyon, who being left unsupported was defeated and killed at Wilson's Creek (Aug. 10). This battle too lacked decisive results. *McCulloch*, having entered Missouri without orders from the Government, retired after his victory into Arkansas, leaving *Price* to continue the struggle with his own resources.

EASTERN VIRGINIA ON THE OUTBREAK OF THE CIVIL WAR BECAME THE MAIN SCENE OF CONFLICT AND THROUGHOUT THE FOUR YEARS, 1861-65, CONTINUED TO BE THE MOST STUBBORNLY CONTESTED GROUND. HERE WAS THE BACKBONE OF THE CONFEDERACY WITH THE CONFEDERATE CAPITAL, RICHMOND. THE MAJOR CAMPAIGNS CONDUCTED IN VIRGINIA BY THE ARMIES OF THE UNION, BEGINNING WITH BULL RUN, LED TO MANY SANGUINARY CONFLICTS, THE MOST IMPORTANT OF WHICH ARE SHOWN ABOVE, AND CULMINATED IN THE SURRENDER AT APPOMATTOX

McClellan in Supreme Command.—The defeat at Bull Run was followed by "the second uprising of the North." Congress authorized the enlistment of 500,000 three-year volunteers, and again recruits poured in. McClellan excelled as an organizer and within three months added 100,000 men to the Army of the Potomac, whose discipline and training rapidly improved under his command. But in October public confidence in him began to abate. Confederate batteries on the lower Potomac, which closed its navigation, were left undisturbed, and the discreditable affair of Ball's Bluff occurred (Oct. 21) where four Federal regiments were ferried over the Potomac to make a reconnaissance towards Leesburg, but were driven back into the river with the loss of over half their numbers. Nevertheless on Scott's resignation he was appointed general-in-chief (Nov. 1). He was expected to open an offensive campaign while the "mud" roads in Virginia were still hard and dry. But though his forces were twice as strong as *Johnston's* at Centreville, he accepted the report of his secret service, which doubled *Johnston's* actual numbers. Moreover, in his new post he was engaged, as will be seen, in organizing the military resources in all theatres of war and despatching expeditions against the Confederate coast. Appreciating the value of sea power he was already contemplating the transfer of his army by water next spring to some point where he would be nearer to Richmond than *Johnston*. But he treated Lincoln with great want of consideration in keeping his plans a secret from him. In December he contracted typhoid fever and was absent from duty for some weeks.

The Confederate generals at Centreville had been vainly pressing *Davis* for reinforcements that they might enter Maryland. They realized the danger of prolonged inaction, while McClellan's army was daily growing stronger. If *Davis* could reinforce them with 20,000 trained men, they proposed to cross the Potomac and by threatening the communications of Washington force McClellan to risk a pitched battle, before he had time to train his raw levies. *Davis* in conference with his generals (Oct. 1) said that he had no reinforcements to spare; he could not withdraw troops from the coast, which was itself threatened with attack. Though the Confederate coastline extended 3,000 m. the Federals could make the blockade practically effective by sealing up the few important harbours and getting possession of the North Carolina "sounds." The forts guarding Hatteras Inlet had been captured (Aug. 29); those protecting the entrance to Port Royal, S.C., fell to another and larger force (Nov. 7); and a third expedition on a still larger scale under Burnside was being equipped against Roanoke island, whose capture would complete the conquest of North Carolina's "inland waters."

What, however, chiefly decided *Davis* to refuse his generals' request was his determination to stand strictly on the defensive in the belief that the war had been won at Bull Run, and that before the spring campaign could open, European intervention would end hostilities. Even in West Virginia, where Rosecrans, McClellan's successor, was pushing forward into the Kanawha valley, no real counter-offensive was attempted. *Lee* after Bull Run was sent to co-ordinate the operations of four separate detachments acting independently of each other. But he failed to produce an effective combination, and after his return to Richmond in October the loss of West Virginia was regarded as inevitable.

In the west, Confederate encroachments upon Kentucky's territory forced it into the war. Frémont, commanding in Missouri, was threatening an expedition down the Mississippi, which would involve the occupation of the Kentuckian shore. Therefore *Polk*, general and bishop, early in September seized Hickman and Columbus, which afforded strong defensive positions on the river, whilst Grant, one of Frémont's brigadiers, promptly replied by occupying Paducah and Smithland at the mouths of the Tennessee and Cumberland. *Polk's* refusal to withdraw his troops, unless Grant set the example, ended Kentucky's neutrality. A new theatre of war was opened up, the great extent of which offered immense possibilities to either side. McClellan on becoming general-in-chief set up in the west two military departments, that of the Missouri embracing all Kentucky west of the Cumberland under Halleck, and that of the Ohio including the rest of Kentucky

under Buell. *Davis* appointed *A. S. Johnston*, one of his ablest generals, to supreme command in the west. *Johnston* advanced into Kentucky and took up a defensive position with his left at Columbus and his right at the important railway junction of Bowling Green, whilst Forts Henry and Donelson in the centre guarded the approaches up the Tennessee and Cumberland. At the outset the Federals were ill prepared to take the offensive. In Missouri, Frémont had left everything in confusion. Kentucky appeared unable or unwilling to defend itself. The troops from the free States north of the Ohio had been largely diverted to West Virginia or Missouri. Lincoln and McClellan were at one in pressing Buell to advance into East Tennessee, Lincoln wishing to send relief to the distressed Unionists there and make of it a second West Virginia, whilst McClellan considered that the success of his campaign in Virginia depended upon the capture of the East Tennessee railway, Richmond's direct line of communication with the west. But the proposed movement presented great difficulties, especially so late in the year, when the roads were almost impassable. There was no railway or navigable river to serve as a line of communication for an invading force, whilst the enemy could bring up troops from east or west over their railway. Buell proposed a different plan. An offensive against *Johnston* should precede any movement into East Tennessee. Halleck with two "flotilla columns" should ascend the Tennessee and Cumberland and break through the Confederate line at its most vulnerable point. Buell would himself advance overland on Nashville, Tennessee's capital. This was the plan of campaign, which when carried out two months later met with brilliant success, but it found no favour with Lincoln, McClellan or Halleck. A small Confederate force advancing through Cumberland Gap into Kentucky was defeated by Thomas at Mill Springs (Jan. 19, 1862). This victory cleared the way for an advance into East Tennessee, but before Buell could follow it up, his attention was called to another quarter by an unexpected move on Halleck's part.

Beyond the Mississippi *Price* had marched north towards the Missouri, gathering up recruits as he went. All over the State, except in St. Louis, Southern sympathizers took up arms to avenge the violation of their "State rights." *Price*, not strong enough to attack St. Louis, aimed at crossing the Missouri to join the secessionists in the north of the State. He captured Lexington (Sept. 20). But Frémont's advance with 40,000 men forced him to retreat to the southwest border. Frémont followed in pursuit to Springfield, where he was relieved of his command (Nov. 2). He had won fame as an explorer in the Rockies, and in California during the Mexican War, and had been a candidate for the Presidency in 1856, but he now proved incompetent both as an administrator and in the field and was held responsible for Lyon's defeat. When *Polk* from Columbus established a post at Belmont on the Missouri bank, Grant descended the river and attacked Belmont (Nov. 7). He was eventually driven back to his boats and forced to re-embark. During the winter Halleck restored order out of chaos and made all preparations for driving *Price* finally out of the State.

On his return to duty in mid-January 1862 McClellan found two changes, both destined to affect his fortunes adversely. Congress had appointed a joint committee of the two houses on the conduct of the war, and Stanton had become secretary of war. McClellan now revealed his new plan of campaign to Lincoln, who first rejected it, but three days later reopened the discussion. McClellan offered a choice of three oversea routes, stating his own preference for a movement to be made with great secrecy to Urbana on the lower Rappahannock, where he would be within 50 m. of Richmond. He expected by a rapid advance from that base to cut off a Confederate force in the Yorktown peninsula and capture Richmond, before *Johnston* could intervene. Lincoln did not see how the preparations could be kept secret, and was sure that McClellan would still find *Johnston* between himself and Richmond. He objected to any movement which uncovered Washington and withdrew McClellan from interposing between the capital and *Johnston*. He gave, however (Feb. 27), a grudging assent to an oversea movement without specifying the actual point of disembarkation. Finally he forbade the Urbana plan and left

McClellan his choice between landing at Fortress Monroe at the end of the Yorktown peninsula, the route which McClellan considered the worst of the three, and making an overland campaign. McClellan chose the first alternative. Probably the withdrawal (March 9) of *Johnston* behind the Rappahannock reconciled him to the sacrifice of his Urbana plan. Throughout these discussions Lincoln demanded adequate protection for Washington, and McClellan undertook to leave ample forces for the purpose.

The Federal Offensive in the West, Feb.-May 1862.—The weak point in A. S. *Johnston's* line was at the centre, where the

BARTHOLOMEW, EDIN.

THEATRE OF THE FEDERAL OPERATIONS IN THE WEST. FEB.-MAY 1862

Memphis and Ohio railway, which formed the link between his two wings, crossed the Cumberland and Tennessee so close to Fts. Donelson and Henry that the capture of these forts would sever his line of communication with the Mississippi. The Tennessee was navigable as far as Tuscumbia in North Alabama, and the Cumberland up to Nashville. The Confederates had no gunboats on these rivers, and if these forts fell there was nothing to oppose the Federal advance to the Memphis and Charleston (M. and C.) railway, the direct line of communication between east and west. Halleck without orders from McClellan or arrangement for co-operation with Buell ordered Grant (Feb. 1) with 15,000 men and Foote's gunboats to ascend the Tennessee, capture Ft. Henry and destroy the railway bridge. Ft. Henry surrendered to the gunboats (Feb. 6), the garrison escaping to Ft. Donelson. *Johnston* evacuated Bowling Green, sending half his army to Ft. Donelson and retiring with the other half to Nashville. This division of forces proved fatal. The concentration of 18,000 men at Ft. Donelson did not prevent its surrender with the bulk of its garrison to Grant (Feb. 16). *Johnston* abandoned Nashville, which was occupied by Buell (Feb. 24), and took up his position at Murfreesboro, and *Beauregard*, sent from the east to command on the Mississippi under *Johnston*, evacuated Columbus (Mar. 2) after removing its armament to New Madrid and Island No. 10, where he intended to make the next stand against a Federal descent of the river. *Johnston* was thus thrown back to his second line of defence along the M. and C. railway with his wings at Memphis and Chattanooga and his centre at Corinth. Halleck's unauthorized movement had proved a brilliant success, but he was in no hurry to follow it up. Buell proposed that they should unite their forces as far up the Tennessee as possible on the east bank, cross the river and seize the M. and C. railway. The occupation of Corinth would secure control of the Mississippi down to Vicksburg. Halleck preferred to act independently, sending a strong force up the Tennessee to raid the Confederate communications on the west bank. Lincoln gave Halleck the supreme command in the west (Mar. 11) placing Buell under his orders.

Halleck now sent Pope with 20,000 men down the Missouri bank to capture New Madrid and Island No. 10, and summoned Buell from Nashville to Savannah on the Tennessee to join Grant encamped on the opposite bank at Pittsburgh landing. He assumed that the recent campaign had thrown the Confederates perma-

nently on the defensive and that the concentration of his own forces would be effected without interruption. But *Johnston* and *Beauregard*, well served with information by local sympathizers, seized their opportunity. By calling up *Bragg* from Pensacola with 10,000 men they concentrated an army of nearly 40,000 at Corinth before the end of March. *Van Dorn* was bringing 15,000 men from Arkansas, but they could not wait for his arrival. The battle of Shiloh (q.v.) (April 6-7) was one of the most fiercely contested in the war. *Johnston* was killed the first day and *Beauregard* retreated to Corinth. Halleck joined his armies (April 11) and having been reinforced by Pope (April 21), who had captured with the help of the gunboats the garrison (7,000) of Island No. 10 with all its guns and stores, commenced a slow and cautious advance on Corinth. *Beauregard* held on to Corinth till May 30th, when he retreated to Tupelo. The evacuation of Corinth was followed by that of Ft. Pillow below Island No. 10 and Memphis (June 3). The Federal squadron fought and destroyed a Confederate flotilla at Memphis (June 6). With the capture of Corinth and Memphis the Federal offensive virtually ended. They had cleared Kentucky and West Tennessee of the enemy, established themselves on the M. and C. railway, and opened the Mississippi to Vicksburg. But the Confederate army of the west had escaped and would presently take the offensive.

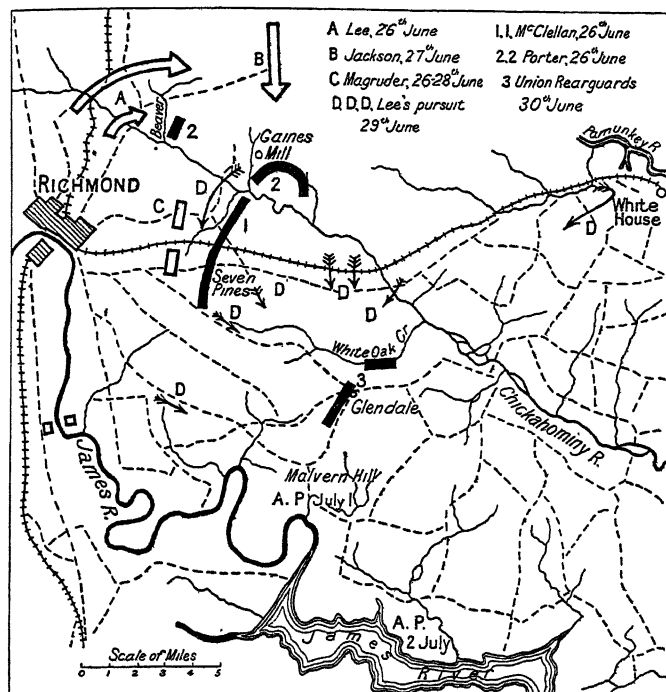

West of the Mississippi Halleck had scored another success. *Price* had been driven out of south-west Missouri by Curtis, who followed him into Arkansas. *Van Dorn*, commanding in the newly formed Trans-Mississippi department, reinforced *Price*, and their combined forces attacked Curtis at Pea ridge (or Elk Horn) but suffered a severe defeat (March 7-8). Still farther west the Confederates had suffered another reverse. A small expedition under *Sibley* had been sent up the Rio Grande to secure Arizona and New Mexico with a view to bringing California into the Confederacy. *Sibley* occupied Santa Fe in March, but was forced by Canby in April to make a disastrous retreat to Texas, and the whole of the territory, which he had overrun, was secured permanently by the Federals. But of all the disasters suffered in the west by the Confederates in the spring of 1862 the greatest, because irreparable, was the loss of New Orleans. Farragut with the Gulf squadron ran past the forts guarding the lower Mississippi and appeared next day before the city (April 24-25), which, abandoned by its garrison, surrendered to the fleet, and was formally occupied by Gen. Butler's troops (May 1).

McClellan's Peninsular Campaign, March-July 1862.—

The sensational appearance of the iron-clad "Merrimac" in Hampton Roads, at the mouth of the James river (March 8), had threatened the collapse of McClellan's overseas campaign, but next day the "Monitor" proved more than her match, and the naval authorities gave a doubtful assurance that they could cover the landing. The embarkation began (March 17); McClellan himself reached Fortress Monroe (April 2). On taking command in the field of the Army of the Potomac he had been relieved of his duties as general-in-chief. For the next four months Lincoln and Stanton were responsible for the "higher strategy." McClellan commenced his advance (April 4), expecting to move rapidly up the peninsula to the neighbourhood of Richmond, where he would fight and win the decisive battle, and capture the Confederate capital. He knew that Yorktown and Gloucester on opposite banks of the York river were fortified, but he counted on the co-operation of the navy to capture Yorktown and intended to land McDowell's corps, which had not yet arrived, on the left bank for the reduction of Gloucester. But the navy could give no help as long as the "Merrimac" was afloat; Lincoln detained McDowell for the protection of Washington on the ground that McClellan had not kept his promise of leaving it absolutely secure. McClellan was held up before Yorktown for a month (April 5-May 3).

J. E. *Johnston*, who had brought his army to the peninsula and assumed command at Yorktown (Apr. 17), slipped away just as McClellan was about to open fire with his siege batteries. A sharp rearguard action took place at Williamsburg (May 5), and an attempt to intercept *Johnston's* retreat by sending a force up the York failed. McClellan established his headquarters at White House on the Pamunkey (May 16). He had succeeded in bring-

ing over 100,000 men (organized into five corps) within striking distance of Richmond, and only 60m. away on the Rappahannock opposite Fredericksburg lay McDowell's corps, now under orders to advance on Richmond on May 26. McClellan would have transferred his base from the York to the James, now open to the Federal war vessels as far as Drewry's Bluff, as the Confederates after the evacuation of Yorktown had abandoned Norfolk and

DISPOSITION OF OPPOSING FORCES JUST PRIOR TO THE RETREAT OF THE FEDERAL ARMIES FROM BEFORE RICHMOND, 1862

destroyed the *Merrimac*, which was unable to ascend the river. But, informed by Stanton that he was to be reinforced, he advanced to the Chickahominy (May 20) and sent two corps across in preparation for the advance on Richmond, keeping three on the left bank to join hands with McDowell. He retained this position with his wings divided by the Chickahominy, although he learnt (May 24) that McDowell's advance was suspended owing to "Stonewall" Jackson's operations in the Valley, hoping that McDowell's movement would shortly be resumed. Johnston concentrated against the two corps on the right bank and brought on the battle of Seven Pines (*q.v.*) (May 31-June 1). He was beaten off, and himself severely wounded the first day. Lee on assuming command withdrew the troops. McClellan moved two more corps to the right bank, leaving one to cover his communications with White House and still hoping for McDowell's coming. Lee's plan was to continue using Jackson in the Valley to prevent McDowell moving south, and at the right moment to bring him to Richmond to take part in the decisive battle. Jackson's successes (June 8-9) served to hold McDowell fast, and Lee learning (June 15) that McClellan's right was "in the air," next day ordered Jackson from the Valley. McClellan had been waiting for the ground to dry, that he might move his siege batteries to the front. On the 25th his outposts were only 4 m. from Richmond, and he telegraphed to Washington that the final advance was about to begin. He was too late. Next day Lee struck and the Seven Days' Battle began (*q.v.*) (June 26-July 2.)

After the defeat of his one corps on the left bank of the Chickahominy (June 27), McClellan decided to "change his base" by a flank march through the White Oak swamp to the James. To cover the passage of his trains he was forced to stand and give battle to Lee, who sought to destroy the Federal army by a combined attack upon its rear and right flank. But, as at Seven Pines, the Confederate commander and his staff failed to co-ordinate the movements of their troops. June 30 was the critical day of the retreat, when the Confederates almost broke through the

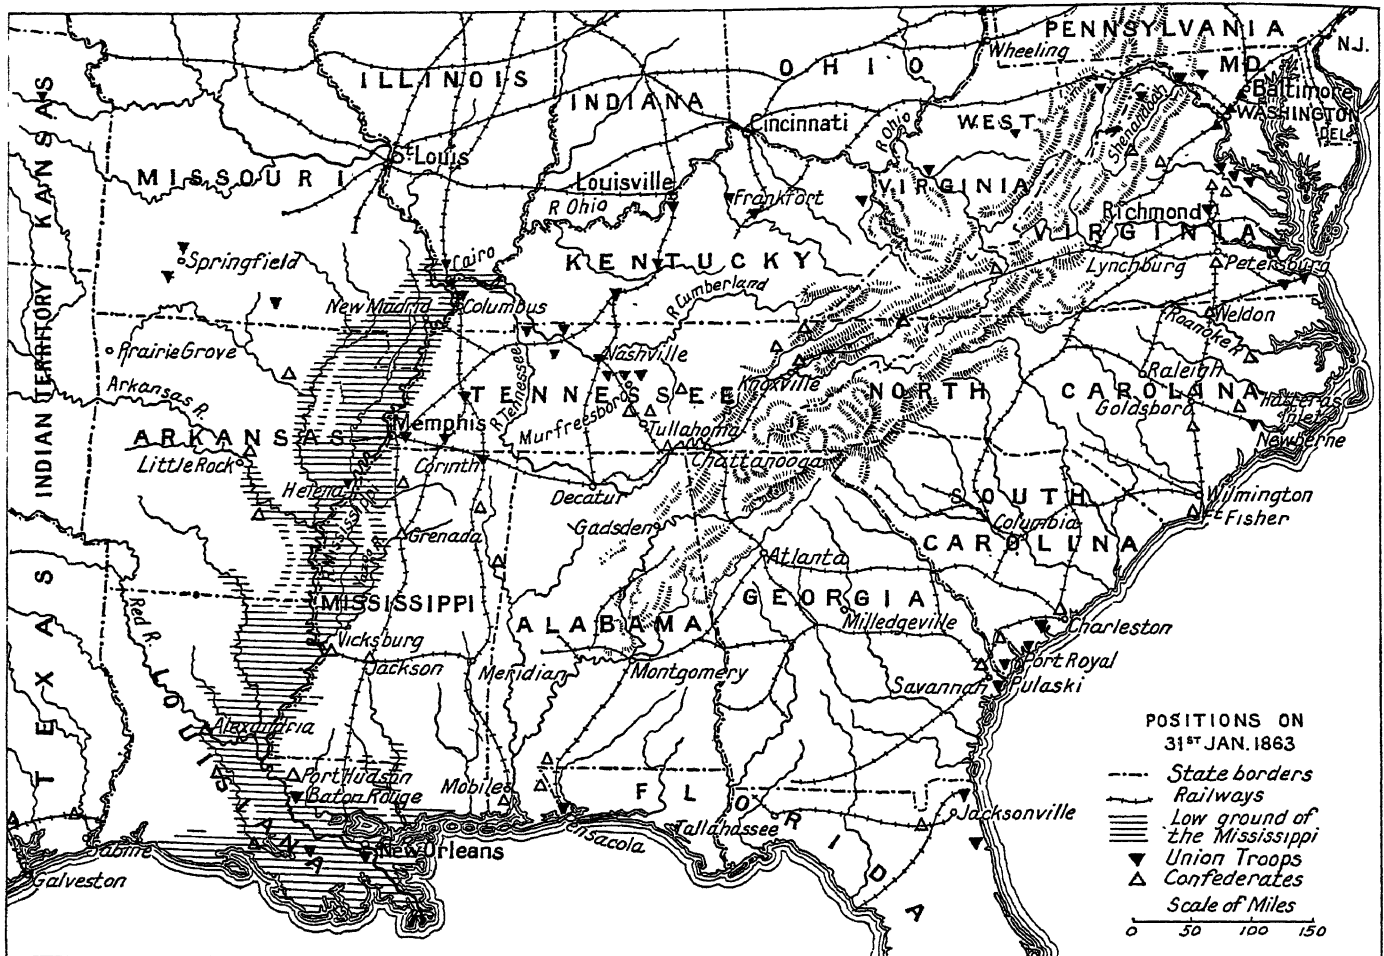

Federal centre, but failed through lack of support to reach the road on which McClellan's trains were moving. After repulsing a final assault at Malvern hill (July 1), McClellan reached the James and entrenched a position at Harrison's Landing. Lee finding that his opponent designed no immediate movement withdrew nearer Richmond (July 8).

McClellan's "change of base" placed him in a position to renew the offensive with good chance of success. He was farther away from Richmond, but his communications were absolutely secure. He could advance on either side of the river. Petersburg lay practically defenceless within his reach and its occupation would enable him to cut Richmond's communications with the south, as Grant did in 1864-65. His army was still numerically stronger than Lee's which had suffered the heavier losses in the week's fighting. It was at first assumed at Washington that he would resume the advance on Richmond, when he received reinforcements. But McClellan demanded 100,000 fresh troops, and Lincoln could not find more than 20,000. Political pressure was being put upon him to replace McClellan. To solve the problem, Halleck was appointed general-in-chief (July 11). A retired engineer officer, who had taken up legal practice, he was an acknowledged authority on the art of war. His recent success seemed to mark him out as McClellan's natural successor, but he proved but little help to Lincoln as a military adviser. He visited McClellan's army (July 25) and committed his first blunder by ordering the withdrawal of the Army of the Potomac to Aquia creek, where it could unite with Pope's Army of Virginia on the Rappahannock for an overland advance on Richmond (Aug. 3).

Jackson's "Valley campaign" is described elsewhere. Here it may be noted that on three separate occasions Jackson caused McDowell's corps to be withdrawn from McClellan. For his attack at Kernstown (March 23) alarmed Lincoln and was partly the cause of his detaining McDowell in the first instance at Washington. Throughout the campaign Lee worked upon Lincoln's anxiety for the safety of Washington to break up the threatened combination against Richmond.

The Confederate Offensive in the East, Aug.-Sept.

1862.—Pope was summoned (June 26) from the west to command an army composed of the forces on the Rappahannock and in the Valley. Jackson's campaign had taught Lincoln that one general is better than three. Pope's immediate task was to lighten the pressure upon McClellan by threatening the Virginia Central railway. Lee despatched (July 13) Jackson in time to save Gordonsville from Pope's cavalry. Jackson advancing towards Culpeper to prevent the concentration of Pope's scattered forces defeated Banks at Cedar Run (Aug. 9), but fell back when Banks was reinforced. Lee joining Jackson with Longstreet's command (Aug. 15) sought to crush Pope, before he could be reinforced from McClellan's army now definitely leaving the peninsula. Pope narrowly escaped being cut off on the Rapidan and retreated behind the Rappahannock. Lee, learning that portions of McClellan's army had disembarked at Aquia creek and were marching to Pope, detached Jackson to make a wide detour through the Bull Run mountains and strike Pope's line of communications at Manassas Junction (Aug. 25-27). Pope, mystified by this movement, made a succession of mistakes and Lee, reuniting his army on the battlefield, drove Pope across Bull Run (*q.v.*) (Aug. 29-30). Pope retired within the fortifications of Washington (Sept. 3). Lee would not allow the second Bull Run to be as barren of results as the first. Having received reinforcements from Richmond, which more than made good his losses, he crossed the Potomac at Leesburg and occupied Frederick (Sept. 7). He entered Maryland partly to "shift the burden of military occupation from Confederate to Federal soil." But his objective was mainly political, to influence the approaching elections in the North, impress Europe with a sense of Southern power and detach Maryland from the Union. Finding his line of communications up the Valley threatened by a strong garrison at Harper's Ferry, he divided his forces (Sept. 10), sending Jackson with the larger half to capture that post, whilst he withdrew the rest behind South Mountain. After the fall of Harper's Ferry he proposed to reunite his army and invade Pennsylvania.

BARTHOLOMEW, EDIN.

McClellan, placed by Lincoln in command of all the forces in Washington, again took the field (Sept. 7). Not knowing what *Lee's* next move might be, he advanced slowly, until a copy of *Lee's* order for the division of his army fell into his hands at Frederick (Sept. 13). He forced the South mountain passes (Sept. 14). *Lee* fell back behind the Antietam, covering a ford over the Potomac.

Jackson with three divisions had crossed the Potomac at Williamsport and appeared before Harper's Ferry from the west (Sept. 13). Other divisions occupied the heights north and east of Harper's Ferry on the opposite banks of the Potomac and the Shenandoah. The garrison (12,500), being completely surrounded, capitulated early on the 15th. Leaving A. P. Hill's division to complete the arrangements for the surrender, *Jackson* started for Sharpsburg and after a night-march rejoined *Lee* on the morning of the 16th with two divisions, and a third arrived later in the day. McClellan reached the Antietam on the 15th, devoted the next day to reconnaissance and fought the battle of Sharpsburg or the Antietam (*q.v.*) (Sept. 17). At the close of the day *Lee* still held his ground, but on the night of the 18th he recrossed the Potomac. His stay in Maryland was too short to produce any effect upon the political attitude of the State and the inhabitants had shown scant signs of sympathy.

The Confederate Offensive in the West, Aug.-Oct. 1862.—Halleck after the fall of Corinth could either follow up *Beauregard's* retreat or strike at Vicksburg or Chattanooga. Pursuit should have ended in the annihilation of the sole Confederate army in the west; the capture of Vicksburg would open the Mississippi to its mouth and cut the Confederacy in two; the occupation of Chattanooga would further Lincoln's policy of sending relief to the Unionists in East Tennessee. Halleck limited his offensive to sending Buell's army alone towards Chattanooga, and wasted three weeks by forcing him to use as his line of supply the M. and C. railway, which was exposed to cavalry raids. At the

end of June Buell gained permission to transfer his base to Nashville. As no movement was made towards Tupelo, *Bragg*, who had succeeded *Beauregard* (June 27), left *Van Dorn* and *Price* to check Grant, who on Halleck's appointment as general-in-chief at Washington was left in command of the department of the Tennessee, Buell resuming command of his original department, and moved the bulk of his army to Chattanooga. He sought the co-operation of *Kirby Smith*, commanding in East Tennessee, in an advance on Nashville, but yielded to the other's confidence in the political results of an invasion of Kentucky and agreed to march to the Ohio. Buell, whose advance from Nashville on Chattanooga was twice suspended in consequence of cavalry raids upon his communications, took up a defensive position at Murfreesboro covering Nashville.

Kirby Smith "turned" Cumberland Gap, swept aside an extemporized force, which faced him at Richmond, Ky. (Aug. 30), and occupied Lexington (Sept. 2), threatening Louisville and Cincinnati. *Bragg*, concentrating behind the Cumberland mountains, appeared on Buell's front (Sept. 5). Then ensued a race to Louisville, in which Buell got the worse of the start, as he dared not uncover Nashville, and reached Bowling Green (Sept. 14) to find *Bragg* planted squarely across the railway between him and Louisville. Buell could not risk an offensive battle with so much at stake; *Bragg* would only fight on the defensive. He moved out of Buell's path owing to lack of supplies (Sept. 21) to make connection with *Kirby Smith*, who had collected a large depot of stores at Lexington. Buell entered Louisville (Sept. 25) and having reorganized his army marched out (Oct. 1) to find and fight the invaders. Their generals were more occupied with the inauguration of a provisional governor at Frankfort (Oct. 4) than with the need for concentrating their forces. An accidental encounter with indecisive results occurred at Perryville (Oct. 8) between Buell's and *Bragg's* left wings. *Bragg* and *Kirby Smith* now united their armies, but only to retreat through Cumberland

GENERALS OF THE UNION ARMY

1. Ulysses S. Grant (1822-85), created general-in-chief in March, 1864. 2. W. S. Hancock (1824-86), commanded a brigade in the Army of the Potomac. 3. W. T. Sherman (1820-91), who made the march through Georgia to the sea. 4. G. B. McClellan (1826-85), organizer of the Army of the Potomac. 5. H. W. Halleck (1815-72), general-in-chief of Union Armies, July 1862-64. 6. "Fighting Joe" Hooker (1814-79), won the

"battle above the clouds." 7. G. G. Meade (1815-72), defeated Lee's Army at battle of Gettysburg. 8. P. H. Sheridan (1831-88), in command of the Army of the Shenandoah. 9. A. E. Burnside (1824-81), in command of the Department of the Ohio, 1863. 10. G. H. Thomas (1816-70), known as the "rock of Chickamauga"

BY COURTESY OF (1, 2, 3, 4, 5, 6, 8, 9, 10) H. P. COOK

GENERALS OF THE CONFEDERATE ARMY

1. R. E. Lee (1807-70), commander-in-chief of Confederate armies, February, 1865. 2. James Longstreet (1821-1904), "General Lee's war horse." 3. J. E. Johnston (1807-91), as commander of army of the Tennessee, conducted the campaign against Sherman in Georgia until July, 1864. 4. T. J. Jackson (1824-63) "Stonewall Jackson," Lee's chief subordinate. 5. J. B. Hood (1831-79), given command of army of the Tennessee, July, 1864. 6. J. E. B. Stuart (1833-64), held a command in army

of Northern Virginia. 7. J. A. Early (1816-94), in command in the Shenandoah valley, 1864-65. 8. A. S. Johnston (1803-62). (Photograph taken during his service in the United States army previous to the outbreak of the Civil War). 9. B. Bragg (1817-76), the commander of the Western Department, 1862-63. 10. P. G. Beauregard (1818-93), opened the war by bombardment of Fort Sumter

Gap into East Tennessee. The Confederate invasion of Kentucky was barren of political results. The provisional governor was chased out of his capital immediately after his inauguration.

The Federals Resume the Offensive, Nov.-Dec. 1862.—Lincoln celebrated *Lee's* retreat with the Emancipation Proclamation. This alienated the Democrats, and if the Administration was to win the autumn elections it must raise its credit by some signal success. McClellan was urged to cross the Potomac and force another battle. He demanded time to reorganize his army. Five weeks passed before he began his advance along the east side of the Blue Ridge. But *Lee*, bringing *Longstreet* to Culpeper, again interposed. McClellan was relieved of his command (Nov. 7) and his successor, Burnside, adopted a new plan of campaign, to transfer his base to Aquia creek, cross the Rappahannock at or below Fredericksburg, and march straight on Richmond. But delay in forwarding a pontoon-train from Washington prevented him crossing till *Lee* had taken up a position on the Fredericksburg heights (*q.v.*). Though the element of surprise was lost, Burnside persisted in crossing the river and, attacking *Lee*, was repulsed with terrible slaughter (Dec. 13).

In the west, Buell was replaced (Oct. 30) by Rosecrans, who as Pope's successor under Grant had gained the credit of defeating *Price* at Iuka (Sept. 19) and *Van Dorn* at Corinth (Oct. 3-4). Before renewing the advance upon Chattanooga he determined to make himself temporarily independent of the railway by accumulating a reserve of 2,000,000 rations at Nashville. For this purpose he had first to repair the Louisville railway, as the Cumberland, like the Tennessee, only became navigable in the latter part of the winter. The Government chafed at the delay. Rosecrans refused to be hurried. He commenced his advance against *Bragg* (Dec. 26), who since returning from Kentucky had established himself at Murfreesboro, where he expected to pass the winter. The battle of Stones river or Murfreesboro (Dec. 31-Jan. 2) ended with *Bragg* abandoning the battlefield, evacuating Murfreesboro and falling back to Tullahoma. Rosecrans occupied Murfreesboro, and settled down for the winter.

After *Van Dorn's* defeat Grant moved against Vicksburg. Sherman starting down the river from Memphis was to land his troops at the mouth of the Yazoo, seize the bluffs north of Vicksburg, and attack the city from the rear, whilst Grant, who was already advancing along the Mississippi Central railway towards Jackson (Mississippi) would hold *Pemberton*, *Van Dorn's* successor, fast and prevent him sending help to Vicksburg. But Grant had to retire when his supply depot was destroyed by a cavalry raid (Dec. 20), and Sherman was forestalled by *Pemberton*, who was kept informed by spies of the Federal movement, and defeated at Chickasaw Bluffs (6 m. north of Vicksburg) (Dec. 29). In north-west Arkansas *Hindman* was organizing a fresh invasion of Missouri but was anticipated by Blunt and Herron, who crossed the frontier and defeated him at Prairie Grove (Dec. 7).

Operations in the East, 1863: Chancellorsville and Gettysburg.—After "the horror of Fredericksburg" the two armies passed the winter facing each other across the Rappahannock. Hooker replaced Burnside (Jan. 26) and quickly restored the shaken *moral* of his army. *Lee* found great difficulty in feeding his troops, and by direction of the war department *Longstreet* with two divisions was sent to the south bank of the James to collect provisions in the vicinity of Suffolk, which was in Federal occupation. *Longstreet* invested Suffolk and at the moment, when his divisions were urgently needed on the Rappahannock, was engaged in a futile siege 120 m. away.

Both *Lee* and Hooker were eager to take the offensive. *Lee* had been considering with *Jackson* an invasion of Pennsylvania, but in the absence of *Longstreet's* divisions had to resign the initiative to Hooker. The latter aimed at forcing *Lee* out of his entrenchments by a wide turning movement over the upper fords of the Rappahannock above its junction with the Rapidan, and sent his newly organized cavalry corps to destroy the railways in *Lee's* rear and intercept his retreat. He thus deprived himself of "the eyes of his army," and to the absence of his cavalry (except one brigade) was largely due the failure of the Chancellorsville campaign (*q.v.*).

Hooker, who outnumbered *Lee* by fully two to one, concentrated the larger half of his army about Chancellorsville (April 30), whilst Sedgwick crossed the Rappahannock below Fredericksburg. *Lee*, leaving 10,000 men to check Sedgwick, threw Hooker on the defensive (May 1), outflanked and rolled up his right wing with *Jackson's* corps (May 2), drove him out of his entrenchments to a fresh defensive position (May 3), turned on Sedgwick, who had captured the Fredericksburg heights, and forced him back over the river (May 4), and then counter-marched to Chancellorsville to strike another blow at Hooker. But the latter retreated across the Rappahannock on the night of May 5. *Lee's* victory was dearly bought at the price of *Jackson's* life (May 10). He now reorganized his army into three corps under *Longstreet*, *Ewell* and *A. P. Hill* and prepared to carry out his plan of invading Pennsylvania.

Longstreet had proposed another plan, viz., to utilize the advantage of the "interior lines" for the relief of Vicksburg now in dire straits. *Lee* should leave the army, which had fought at Chancellorsville, to "contain" Hooker on the Rappahannock, and with *Longstreet's* two divisions join *Bragg* in Tennessee. *Johnston's* troops should be brought from Mississippi and *Buckner's* from East Tennessee to the same point. The united forces under *Lee's* command could then take the offensive against Rosecrans with a good prospect of overwhelming him. If victorious, *Lee* should then invade Kentucky and threaten Louisville and Cincinnati as the most likely means of forcing Grant to raise the siege of Vicksburg. But *Lee* was unwilling to leave Virginia or divide his army.

Lee's objects were much the same as had prompted his invasion of Maryland in 1862, and in particular he hoped to levy much-needed supplies of food and clothing from a free State and at least prevent reinforcements being sent to Grant before Vicksburg. He commenced his movement on June 3. His plan of campaign was to transfer his army to the Valley, cross the Potomac and march to the Susquehanna. He could count upon Lincoln's anxiety for Washington's safety keeping Hooker from attacking any of his widely separated corps before they were concentrated in Pennsylvania. He left *Hill* at Fredericksburg till Hooker should withdraw northwards, and *Longstreet* at Culpeper formed the link between *Hill* and *Ewell* pushing down the Valley. A cavalry battle at Brandy Station (June 9) warned Hooker that *Lee* was on the move. Being refused permission to march on Richmond, he began to fall back towards Manassas (June 13). *Hill* marched to the Valley covered by *Longstreet*, who advanced east of the Blue Ridge. *Ewell* captured Winchester (June 15) and crossed into Maryland, pushing his cavalry forward into Pennsylvania. *Longstreet* passed into the Valley in *Hill's* rear and their two corps were crossing the river on June 23-24. Hooker began crossing on June 25 and concentrated at Frederick, threatening *Lee's* line of retreat. *Hill* and *Longstreet* were at Chambersburg, *Ewell* on his way to Harrisburg with two divisions at Carlisle and one at York (June 27). But the absence of *Stuart's* cavalry, which was on a raid round the Federal army, and did not rejoin till July 2, left *Lee* in ignorance of Hooker's movements. He did not learn till the night of the 28th that Hooker had crossed into Maryland and was threatening his communications. He at once ordered a concentration of all his forces at Cashtown to keep the Federals east of South Mountain by threatening Baltimore. Meade, who had replaced Hooker (June 28), was moving his army northwards to prevent *Lee* crossing the Susquehanna. A chance encounter on June 30 at Gettysburg (*q.v.*) brought on the famous battle.

Hill advancing from the west and *Ewell* coming down from the north had defeated two Federal corps and occupied Gettysburg (July 1). Neither *Lee* nor Meade expected a battle so soon, but *Lee* could complete his concentration first, and the chance of defeating his opponent in detail urged him to assume the offensive. But he could not get his corps commanders to work together as a team. No attack was delivered (July 2) till 4 p.m., and though the Confederates gained some ground on both flanks and for a moment broke through the Federal centre, at nightfall Meade still held Cemetery Ridge and had his whole army concentrated. *Lee* made his final assault (July 3) with two divisions against the enemy centre, but again concert of action was lacking, and

Pickett's charge, being unsupported, was a costly failure. *Lee* commenced his retreat (July 4) through the South Mountain passes. He was held up at Williamsport for a week waiting for the river to run down, but on the night of the 13th withdrew his army and trains into the Valley before Meade, who had only appeared on his front the day before, could make up his mind to attack.

Lee gradually fell back behind the Rapidan and Meade followed him across the Rappahannock as far as Culpeper. Both armies were weakened in September by sending heavy detachments to Tennessee. In October and November the two generals engaged in a campaign of manoeuvre, which had no decisive result and left them in their original positions on the Rapidan and Rappahannock respectively.

Operations in the West, 1863: Vicksburg and Chattanooga.—In 1863, as in 1862, it was in the west that decisive results were obtained. By the capture of Vicksburg and Port Hudson the Federals gained complete control of the Mississippi, and in East Tennessee they captured Chattanooga and Knoxville. Grant's Vicksburg campaign (*q.v.*) was one of the most brilliant operations of the war, though he owed much to his opponent's mistakes.

The problem was to transport his army from the right bank of the Mississippi to the high ground in the rear of Vicksburg. After four unsuccessful attempts (Feb.–March) to open up a water-route, by which the enemy's flanks might be turned, Grant in April, when the winter-floods had begun to subside, moved two corps by land to a point below Grand Gulf, the extreme left of the Confederate defences. Part of the Federal fleet had run past the Vicksburg batteries by night (April 16), bringing with them two transports, and five more transports got past six nights later. Grant began crossing the river (April 30). *Pemberton*, who as commander of the Department of Mississippi and East Louisiana was responsible for both Vicksburg and Port Hudson, had been so mystified by Grant's demonstrations on the north side of Vicksburg that he had only four brigades available to meet his advance south of the Big Black river. Grant defeated these (May 1) and established a temporary base at Grand Gulf. Having been joined by Sherman with further supplies, he advanced (May 7) against the Vicksburg–Jackson railway, on which *Pemberton* depended for supplies and reinforcements. But suspecting after the engagement at Raymond (May 12) that a considerable force was collecting at Jackson, Grant cut loose from his base and marched with his whole army on Jackson, living off the country till he could work round to the north of Vicksburg and establish a new base on the Yazoo. *J. E. Johnston*, commander-in-chief in the west, had been ordered (May 9) to go and assume personal command of the troops in Mississippi. He reached Jackson from Tullahoma (May 13) but found only two brigades there. Next day, after fighting a delaying action at Jackson, he retreated up the Mississippi Central railway to Canton. Grant then fell upon *Pemberton's* field-force at Champion's Hill (May 16) and drove it into the fortifications of Vicksburg, occupying Haynes's Bluff two days later. The fate of Vicksburg was now sealed. For *Johnston* was unable to collect a force strong enough to create a diversion, and *Pemberton* capitulated (July 4).

Butler's successor at New Orleans was equally successful in reducing Port Hudson, 200 m. below Vicksburg (July 9). Farragut with two warships had run past the Port Hudson batteries (Mar. 14), and by closing the mouth of the Red River deprived the garrison of its main source of supplies. Banks commenced siege operations (May 24), and the Confederates were on the verge of starvation when they surrendered.

For several months Rosecrans and *Bragg* remained watching each other in Middle Tennessee, confining themselves to cavalry raids against each other's lines of communication. Rosecrans was urged by the Government to take the offensive against *Bragg* to prevent him sending reinforcements to Mississippi. But Rosecrans maintained that, while he remained on *Bragg's* front, the latter would not risk the loss of Middle Tennessee by detaching troops elsewhere. *Bragg* did in fact send some reinforcements to *Johnston*. Rosecrans was really afraid that Grant might be

defeated and was unwilling to commit himself to a fresh movement while the issue at Vicksburg remained unsettled. At last he advanced (June 23) and in nine days of incessant rain manoeuvred *Bragg* out of two strong positions in succession and forced him to retreat behind the Tennessee. He resumed his advance (Aug. 16) in co-operation with Burnside, who advancing from Kentucky occupied Knoxville (Sept. 2). Rosecrans feinting at *Bragg's* right, as if he intended to cross the Tennessee above Chattanooga and join Burnside, moved the bulk of his army across well below Chattanooga (Sept. 4) and advanced over the mountain ranges south of the river against *Bragg's* line of retreat. This manoeuvre forced *Bragg* to evacuate Chattanooga (Sept. 8), but he retreated only 25 m. to Lafayette, where he covered the railway, waiting for a chance of defeating Rosecrans's army in detail. Rosecrans, imagining *Bragg* to be in full retreat, fell into the trap and pressed forward with three columns so widely separated that no two were within supporting distance of each other. But *Bragg* failed to close the trap. Two chances of overwhelming isolated portions of the Federal army were lost by his lieutenants. Rosecrans concentrated his army (Sept. 18), and *Bragg*, having received considerable reinforcements, including five brigades under *Longstreet*, from Virginia, attacked and defeated him (Sept. 19–20) in Chickamauga valley (*q.v.*) and drove him back into Chattanooga, where the Federal army was practically besieged and in danger of starvation. Grant was now appointed to the supreme command in the west and reached Chattanooga (Oct. 23), where Hooker with reinforcements from the Army of the Potomac had already arrived. Grant substituted Thomas for Rosecrans in command of the Army of the Cumberland and averted all fear of starvation by opening a short line of communication with Bridgeport by way of two ferries over the Tennessee. *Bragg* now weakened himself by sending *Longstreet* with a large detachment against Burnside (Nov. 3). Grant on the arrival of four divisions of the Army of the Tennessee under Sherman took the offensive and stormed *Bragg's* position on Missionary ridge, which overlooked Chattanooga (*q.v.*) (Nov. 25).

In his anxiety for Burnside's safety Grant ceased his pursuit of *Bragg's* retreating army (Nov. 28) and despatched Sherman to Knoxville, where *Longstreet* was besieging Burnside. After failing in an assault upon the Federal works (Nov. 29), *Longstreet* raised the siege (Dec. 4) on Sherman's approach and retreated up the Holston valley. The greater part of East Tennessee was now in Federal hands.

Grant in the East, 1864.—Halleck having failed during 18 months to co-ordinate from Washington the movements of the Federal armies, Grant was commissioned (March 9) lieutenant-general, a grade revived by Congress, and appointed general-in-chief to command in the field. Deeming his presence more urgently needed in the east, he attached himself to the Army of the Potomac, retaining Meade in actual command. Sherman succeeded him in the west. The presidential election was due in November. The North was war-weary, and Lincoln's chance of re-election would be small unless speedy victory were in sight. Grant's was a policy of attrition, aiming at the exhaustion of the only two enemy armies of considerable size still in the field, viz., *Lee's* in Virginia and *Johnston's* in Georgia, by concentrating against them all the force available. For Meade's army not Richmond, but *Lee's* army was the objective. Grant designed to flank *Lee* out of his entrenchments behind the Rapidan and wear him down by "continuous hammering." He could afford to lose two men to *Lee's* one, because Southern man-power was nearly exhausted. But he also sought to create a diversion by threatening Richmond and its railway communications on both flanks. Columns were ordered to march on Staunton and Lynchburg, and then unite for a movement against Richmond; the Army of the James was to advance up the south bank of the James River. But in allowing Butler to command this army, Grant made a grievous mistake. B. F. Butler, a criminal lawyer and influential politician, had shown no military capacity in his various commands, but he was a dangerous man to alienate in a presidential year.

Grant crossed the Rapidan (May 4). After two days' battle in the Wilderness (*q.v.*) he moved by the left flank to Spottsylvania

vania and continued this "side stepping" manoeuvre till close to Richmond. But in these forty days he never got *Lee* into the open. On the Po, North Anna, Totopotomoy and at Cold Harbor he found *Lee* entrenched across his path. No diversion came from Butler, who missed the opportunity of capturing Petersburg in the first week and was "bottled up" by *Beauregard* (May 16). The other subsidiary movement was nearly as unsuccessful.

After Grant's defeat at Cold Harbor (June 3) *Lee* detached *Early's* corps to save Lynchburg from Hunter, who had already captured Staunton. Hunter retreated into West Virginia, leaving the Valley open to *Early*, who marched down it, crossed the Potomac, defeated a scratch force on the Monocacy (July 9) and appeared before Washington (July 11). Grant sent back one corps for the protection of the capital. But *Early* withdrew (July 12) and retired into the Valley, having given Washington and Baltimore a sudden fright, but without seriously deranging Grant's plans. Grant's casualties had reached 55,000, and though probably he inflicted as heavy losses on *Lee* in proportion, he had to part with 36 time-expired regiments, and the reinforcements, which kept up his numbers, could not replace the veterans of the old army.

Grant's finest achievement was the transfer of his army across the Chickahominy and the James unopposed under *Lee's* nose (June 12-15), but he lost the chance of capturing Petersburg (June 15-18), which *Lee* was slow to reinforce (*q.v.*). The ensuing siege of Petersburg was "trench warfare" and a siege only in name, as *Lee's* army was never invested. Grant's aim was to extend his lines to his left so as to get possession of the railways from the south and south-west to Petersburg and Richmond, whilst making demonstrations on the north bank of the James and "feeling" the Richmond defences. The fiasco of the "Burnside mine" (July 30)—when a mine was successfully exploded under a salient in the Confederate lines, but the assaulting troops owing to the mismanagement of Burnside, the corps-commander on whose front the attempt was made, were repulsed with heavy loss—warned him against frontal attacks on *Lee's* lines round Petersburg. He secured a considerable section of the Weldon railway, but at the end of the year *Lee* still held the Southside and Danville lines.

The only Federal successes in the east this year were won by Sheridan in the Valley (*q.v.*). Sent by Grant to drive out *Early*, he won three victories in a month (Sept. 19-Oct. 19) and completely devastated the Valley, which had become the granary of Richmond. These victories, coupled with Sherman's capture of Atlanta (Sept. 2), secured Lincoln his overwhelming triumph over the Democratic candidate, Gen. McClellan.

Sherman in the West, 1864.—Sherman with three armies under Thomas, McPherson and Schofield confronted *Johnston*, who had taken command of *Bragg's* beaten army.

The Richmond Government had wished *Johnston* to effect a junction with *Longstreet* and invade Middle Tennessee, but *Johnston* finding his army in no condition to take the offensive remained at Dalton, where he occupied a strong defensive position. Grant's instructions to Sherman were "to move against *Johnston's* army, to break it up and to get into the interior of the enemy's country as far as you can." To Grant the destruction of the enemy army was the primary objective, but Sherman thought more of occupying strategic points in Confederate territory. Atlanta, *Johnston's* base, was at the junction of four important railways and "full of foundries, arsenals and machine-shops. Its capture would be the death-knell of the Confederacy" (Sherman). Eventually Sherman captured Atlanta but let the Confederate army escape. He had about the same superiority of numbers as Grant had, roughly 100,000 against 60,000, and was as far from Atlanta as Grant was from Richmond. But as compared with Grant he had one great disadvantage. He was practically tied to the railway and could not be continually shifting his base. Grant had intended that Banks should effect a diversion in Sherman's favour by a movement on Mobile in co-operation with Farragut's fleet. But Banks was not available, having been previously sent by Halleck up the Red River to establish at Shreveport a base for the military occupation of

northern Texas, the Government fearing that the French in Mexico were planning to establish an independent republic in Texas.

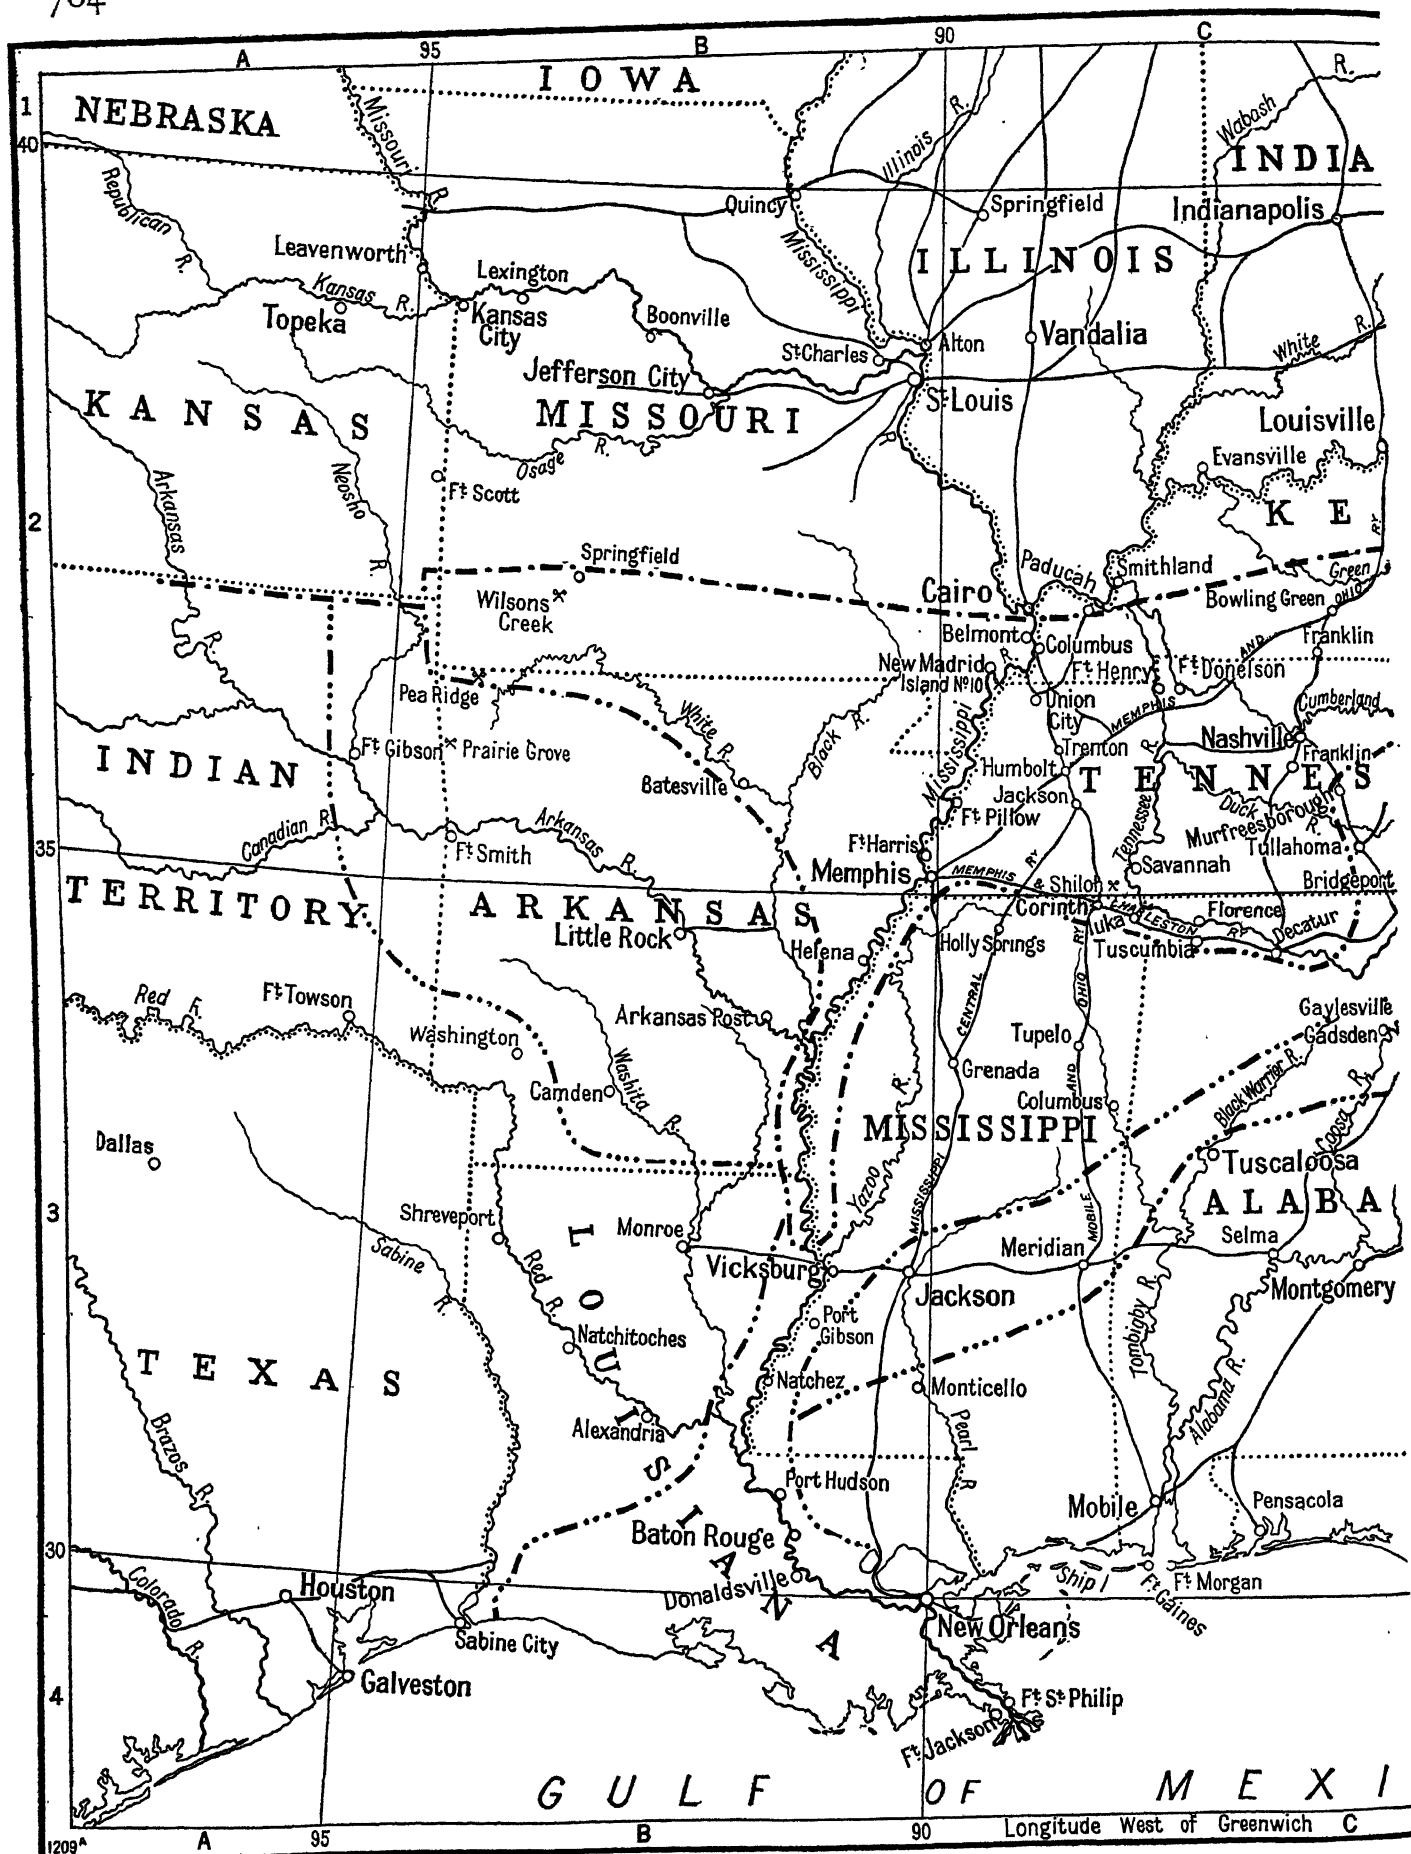

The campaign opened (May 4). Between Dalton and Atlanta the railway crossed three rivers, the Oostanaula at Resaca, the Etowah and the Chattahoochee.

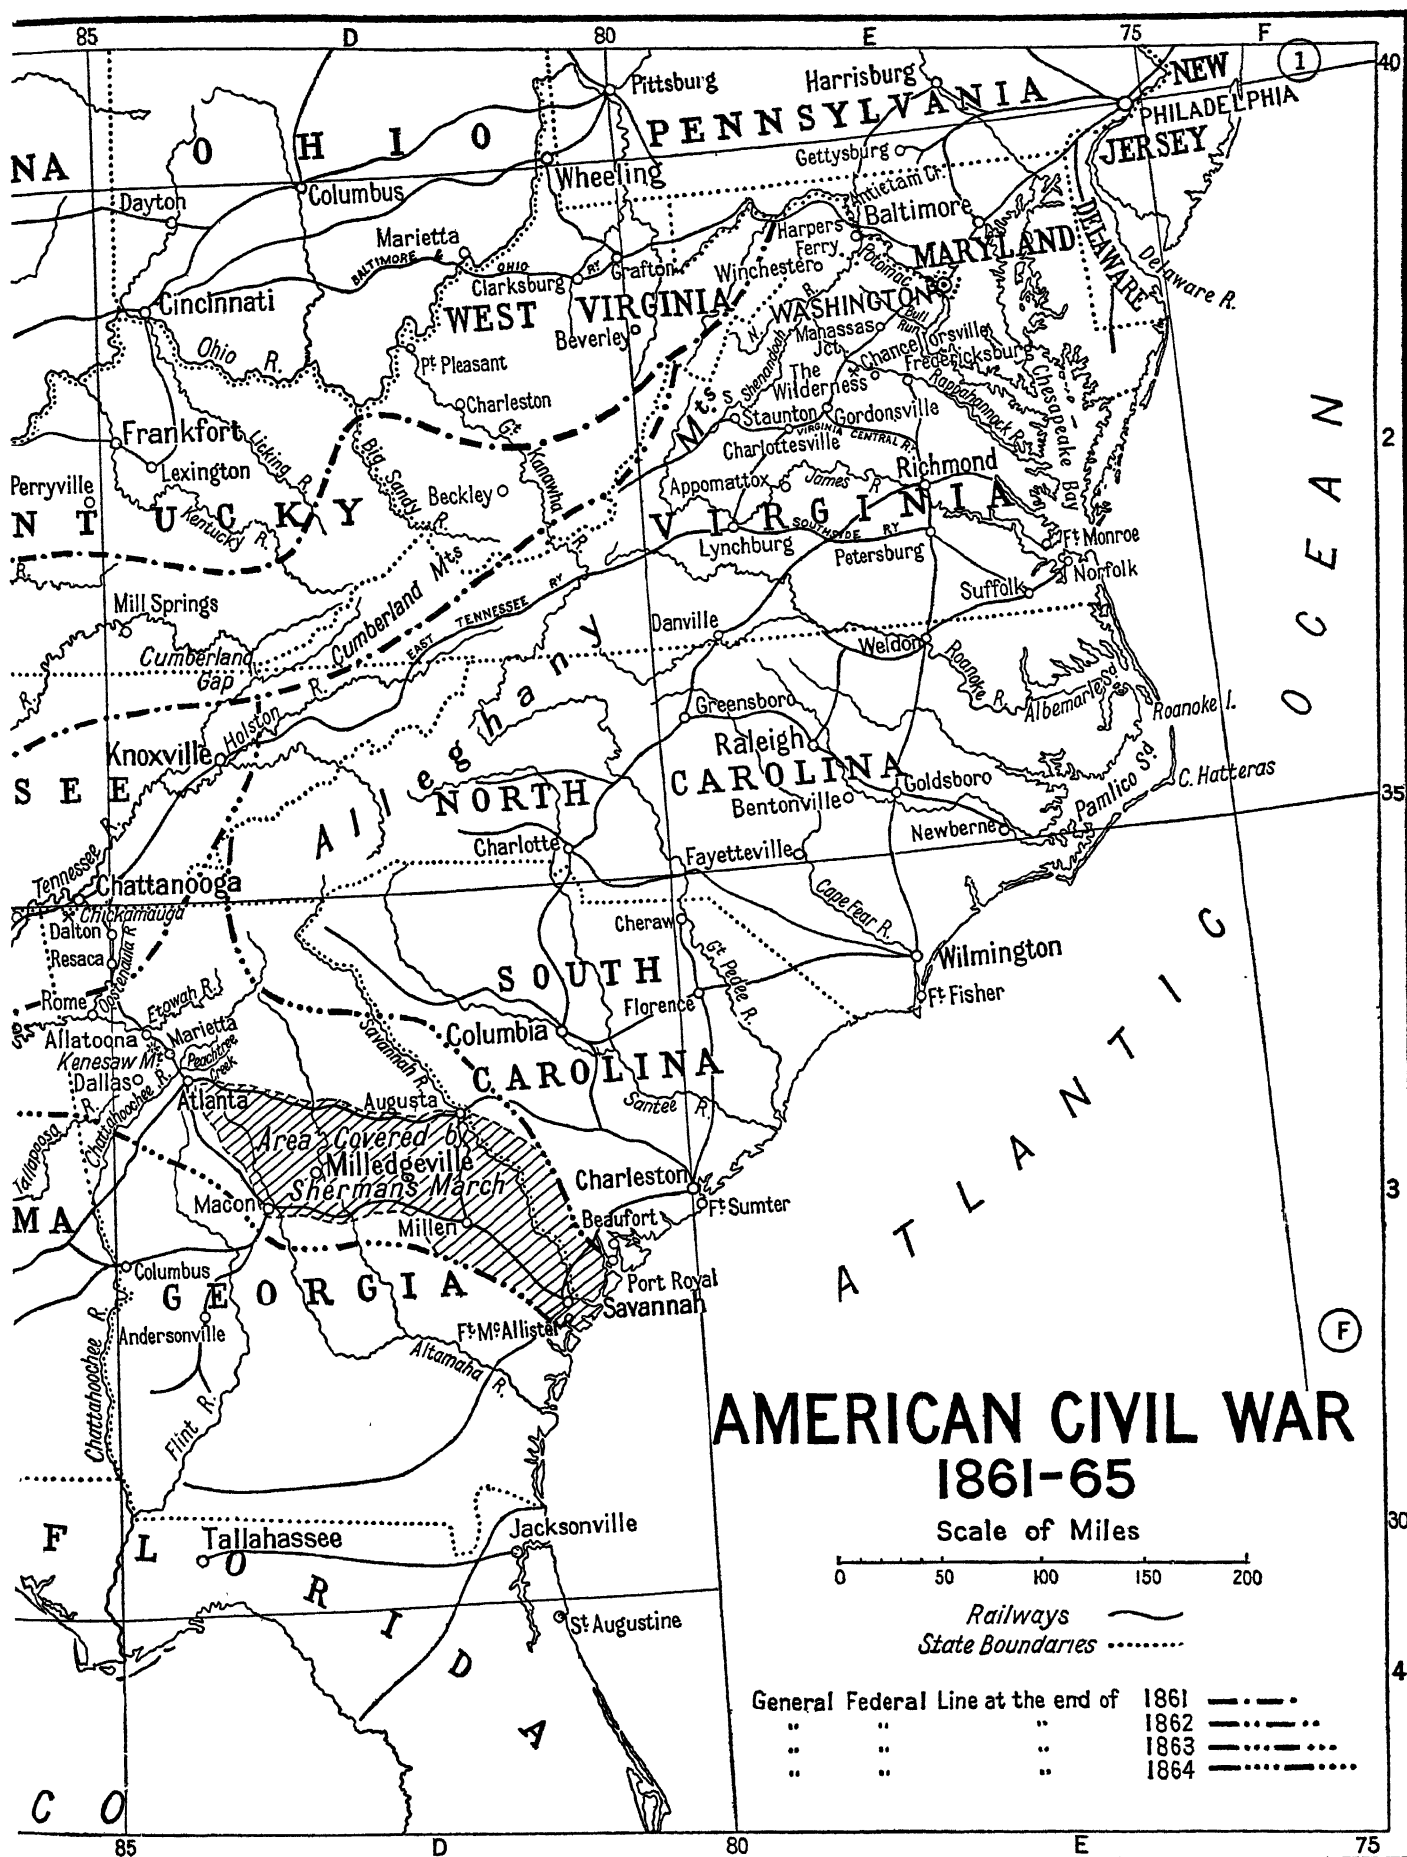

Johnston's policy was to delay Sherman's advance as much as possible, withdrawing from his successive positions before he could be drawn into a pitched battle except upon his own terms. He was prepared to fall back as far as Atlanta, which he regarded as impregnable, "too strong to be taken by assault and too extensive to be invested." Sherman's general plan of campaign was to keep Thomas's army in the centre to "contain" *Johnston's* army, for which it was in itself a match, and use the other two to turn his flanks. With McPherson's army he outflanked *Johnston's* left and forced him to evacuate Dalton (May 13) and Resaca (May 15). In the comparatively open and rolling country between the Oostanaula and the Etowah *Johnston* expected to be able to make a stand and give battle, but his corps commanders dissuaded him, and retreating across the Etowah (May 20) he took up a strong position in the mountain pass at Allatoona.

By temporarily cutting loose from the railway and marching on Dallas Sherman turned the Allatoona pass and by shifting McPherson over to the left flank gradually forced *Johnston* to contract his lines round Marietta (*q.v.*). Wishing to save his troops the fatigue of yet another flank movement over roads rendered almost impassable by continuous rain, Sherman attacked *Johnston's* lines on Kenesaw mountain (June 27), but was repulsed with heavy loss. Resuming the outflanking movement round *Johnston's* left he manoeuvred him out of the Marietta position (July 2), and a week later *Johnston* withdrew his whole army behind the Chattahoochee, after Schofield had crossed above his right flank. Though in this protracted duel only the engagement at Kenesaw mountain ranks as a battle, skirmishing never ceased, often developing into hard fighting, especially during the operations round Dallas. During May and June Sherman's casualties amounted to about 17,000, and *Johnston's* were relatively, if not actually, greater. *Johnston* was preparing to fall upon Sherman's columns, as they crossed the Peach Tree creek, the only natural obstacle between the Chattahoochee and Atlanta's northern defences, when he was superseded by *Hood* (July 17). *Davis* was tired of *Johnston's* Fabian tactics and believing that he would abandon Atlanta without a battle, put a fighting general in his place. *Hood* promptly fought three battles before the end of July, but was defeated in them all, and evacuated Atlanta (*q.v.*) (Sept. 2). Sherman waited for *Hood's* next move. *Hood* crossed the Chattahoochee (Sept. 29) and striking first at Sherman's communications marched to Gadsden (Alabama) drawing Sherman in pursuit more than room. from Atlanta as far as Gaylesville (Oct. 20). When *Hood* moved still farther west to cross the Tennessee, Sherman started back to Atlanta to execute his long-cherished plan of marching through Georgia to the coast. He left Thomas to deal with *Hood*. But the force assigned to Thomas was barely sufficient for the purpose.

In actual numbers superior to *Hood's* army, it was made up of widely separated commands; one corps was still in Missouri, and until its arrival at Nashville (Nov. 30) Thomas can hardly be said to have had an army at all. Sherman could easily have spared another 12,000 men, and this addition to his strength would have made Thomas's position absolutely safe.

Hood's plan was to destroy Thomas's forces before they could concentrate, capture Nashville, invade Kentucky, threaten Cincinnati and then march through East Tennessee to join *Lee*. But a three weeks' delay at Florence to collect supplies proved fatal. Schofield with 23,000 men had time to take position at Pulaski and delay his advance, whilst Thomas was concentrating his other forces at Nashville. Having failed to envelop Schofield on the Duck river, *Hood* attacked him furiously but unsuccessfully at Franklin (Nov. 30) and appeared before Nashville (Dec. 2). In spite of the severity of his losses and the fact that he was confronted by an army superior to his own, *Hood* was still bent on retaining the offensive and detached his cavalry

against the Federal lines of communication. He remained before Nashville in the vain hope of receiving reinforcements promised from Texas, until Thomas marched out and defeated him in the most decisive battle of the war (*q.v.*) (Dec. 15-16). *Hood* escaped over the Tennessee, but his army as a fighting force practically ceased to exist.

Sherman started from Atlanta (Nov. 15) on his 300m. march with 60,000 men and without encountering any organized resistance reached the outskirts of Savannah (Dec. 10), feeding his army off the country. His purpose was to demonstrate "the hollowness" of the Confederacy and by ruining the railway system of Georgia, now the granary of the South, prevent food reaching Richmond. Georgia was left undefended except by *Wheeler's* cavalry and the State militia, *Hood's* invasion of Tennessee being counted upon to bring Sherman back in pursuit. Sherman, having destroyed 160m. of the Georgia Central railway, by storming Ft. McAllister established communication with the fleet in Ossabaw sound. Savannah was evacuated (Dec. 20). Sherman was now free to join Grant by sea or land.

Though the Confederates still held Mobile, its value as a port was gone. Farragut had forced an entrance into the bay (Aug. 5) and captured the forts guarding the harbour mouth. Only in the Trans-Mississippi had the Confederates gained any success. Banks's Red River expedition proved a complete failure and he retreated to New Orleans. But the Federals retained their hold upon northern Arkansas, including Little Rock, the State capital. *Price* made a last raid into Missouri in September and October.

Collapse of the Confederacy, Jan.-May 1865.—Richmond's fall was near at hand. Grant's next advance would plant him on the Southside railway. *Lee* had not sufficient troops to hold a further extension of his lines. Desertion was thinning his ranks; conscription had broken down. Wilmington, the last Confederate port, was closed by the capture of Ft. Fisher (Jan. 15). A peace conference held in Hampton Roads failed (Feb. 3) because *Davis* still insisted on the recognition of Southern independence. Congress forced *Davis* to appoint *Lee* (Feb. 9) commander-in-chief of all the Confederate forces. But this step came too late; *Lee* could only appoint *Johnston* to command such troops as could be mustered to meet Sherman. For Grant, having decided that to the Army of the Potomac should fall the honour of capturing Richmond, ordered Sherman to march up through the Carolinas, and to provide him with a base on the coast, brought Schofield round from Nashville to North Carolina to capture Wilmington. Sheridan with 10,000 cavalry moved from the Valley to White House (March 19) in time for Grant's next advance. *Lee* had determined to withdraw his army to Danville and effect a junction with *Johnston* against Sherman. But his artillery horses and transport animals were in no condition for hard work, until the roads improved. To prevent Grant extending to the left, *Lee* attempted a diversion by attacking Ft. Stedman (March 25) on the right of the Federal lines. After the repulse of this sortie Grant ordered a general advance by the left flank. Sheridan's victory at Five Forks (April 1), beyond the extreme right of *Lee's* lines, where with his cavalry and Warren's corps he defeated *Pickett's* division and *Fitzhugh Lee's* cavalry, gave the Federals possession of the Southside railway. Next morning Grant broke through *Lee's* lines on a broad front, driving him back into the suburbs of Petersburg. That night *Lee* commenced his retreat. Richmond surrendered (April 3). *Lee* having been forced by Sheridan from the Danville road to the north bank of the Appomattox surrendered (April 9).

Sherman advanced (Feb. 1) and occupied Columbia (Feb. 17), which was accidentally burnt. Charleston was evacuated (Feb. 18). Although the march over swollen rivers and swamps was most arduous, Fayetteville, N.C., was occupied (March 11), where communication was established with Wilmington, which had been captured (Feb. 22). Sherman now aimed at Goldsboro to effect a junction with Schofield, who had left Wilmington for New Berne. To prevent this junction *Johnston* attacked Sherman's left wing at Bentonville (March 19), but withdrew his forces and retreated to cover Raleigh (March 21). Sherman

joined Schofield at Goldsboro (March 23). From Goldsboro Sherman moved out against *Johnston* (April 10) and occupied Raleigh (April 13). Next day *Johnston* asked for an armistice. The assassination of Lincoln (April 14) caused a delay, but *Johnston* finally surrendered at Greensboro (April 26). In the lower South, Wilson conducted a brilliant cavalry campaign in Alabama, defeating *Forrest* and capturing Selma (April 2), the last Confederate arsenal, and Canby, Banks's successor, captured Mobile (April 12). *Taylor* surrendered the Confederate forces in Alabama and Mississippi to him (May 4), and *Kirby Smith* surrendered the Trans-Mississippi forces (May 26). *Davis* was captured by some of Wilson's cavalry (May 10).

The Navies and the Blockade.—The United States navy was quite unprepared for war. Half of the 34 steamships available for service were on foreign stations and the home squadron comprised only seven steamers and five sailing ships. The navy department was slow to recognize the value of armour plate for warships and let the Confederates get the start with the "*Merrimac*." *Mallory*, secretary of the navy, aimed at providing three types of warships: armoured rams for coast defence, sea-going ironclads to destroy the blockading squadrons and commerce-destroyers. The last two classes he hoped to build or purchase in Europe. The "*Merrimac*" and the "*Monitor*" represented the types of ironclad constructed by the two combatants respectively. The former, a U.S. frigate, which had been fired and scuttled at Norfolk, was raised and cut down to a ram with a wooden casemate, protected by armour and carrying ten heavy guns, erected upon her hull. At her first appearance in Hampton Roads she sank two wooden sailing vessels, the "*Cumberland*" and "*Congress*," but next day, after a drawn battle with the "*Monitor*," retired to Norfolk. Altogether 12 of these ironclads were constructed, but the weakness of their engines rendered them less formidable than was expected. The Confederates, unable to build engines in their workshops, had to use for their ironclads either the old ones or those which they took out of other steamers. The main features of the "*Monitor*," designed by Ericsson to counter the "*Merrimac*," were the revolving turret, the low free-board and the projecting overhang. She drew less water and was more easily handled. The Federals built a large number of monitors, which, though more than a match for the rams, were comparatively ineffective against forts, as was proved by the failure of the naval attack on the Charleston forts (April 7, 1863). The river "ironclads," which fought in the waters of the west, were gunboats constructed by Eads with a partially armoured casemate. To the original nine, five more were added in 1863, more heavily armoured and powerfully armed. Three single-turret ironclads of light draught were specially constructed for the Red River expedition.

Two powerful ironclads were built in England for the Confederates, but the British Government prevented them sailing. One ironclad built in France passed into Southern hands, but reached Havana too late to take part in the war. Three commerce-destroyers built or purchased in England drove the Federal mercantile marine from the seas. Having auxiliary sail power they could economize coal. The "*Alabama*" during her 22 months' cruise never put into a Confederate port. She captured 68 prizes in the Atlantic, Indian ocean and China sea, sank the Hatteras gunboat off Galveston but was herself sunk off Cherbourg by the sloop-of-war "Kearsarge" (June 11, 1864). The "*Shenandoah's*" objective was the whaling fleet in the North Pacific, which she destroyed (June 1865), having no official news that the war was over. The Geneva Arbitration (1872) found Great Britain responsible for the losses inflicted by these three cruisers to the amount of \$15,500,000.

The Federal navy concentrated upon blockading the seven principal southern ports. Lincoln had proclaimed a blockade of the Southern coast (April 19, 1861). But for many months it was little more than nominal for lack of ships which could enforce it. An attempt to close Charleston harbour by sinking stone-laden hulks in the entrance proved a failure. Not till the middle of 1862 could the blockade be regarded as even moderately effective. Then with the export of cotton at last unrestricted

and an increasing demand in the English market, vessels specially adapted for blockade-running were built in the English ship-yards, and in spite of the Federal navy blockade-running only ceased to be a profitable speculation when the ports were actually in Federal occupation. Savannah had been practically closed since the capture of Ft. Pulaski (April 1862). The loss of Charleston and Wilmington left the Confederacy without an Atlantic port, and reduced the armies of *Lee* and *Johnston* to a state of destitution.

Conclusion.—The collapse of the Confederacy was so sudden and complete that it took Europe by surprise. Sherman's "march to the sea" first opened foreign eyes to the probability of Southern defeat. But by the end of 1863, when *Lee* had suffered defeat at Gettysburg and *Bragg* had finally lost Chattanooga, and the Federals had recovered the Mississippi between Vicksburg and Port Hudson, thus completely isolating the Trans-Mississippi department, ultimate defeat stared the Confederacy in the face. The sole remaining hope was that the North through sheer war-weariness might throw away the victory already won. When Grant seemed fought to a standstill by *Lee* round Richmond in the summer of 1864, and between Sherman and Atlanta *Johnston's* army interposed still unbeaten, the North very nearly reached the limit of its endurance. The Democrats put forward a programme, the first article of which pronounced the war a failure. Lincoln despaired of re-election. But the fall of Atlanta and Sheridan's triple victory over *Early* in the Valley came in time to turn the scale in favour of the Government. Gradually too the significance of Grant's position in front of Petersburg began to be realized. *Lee* had lost the power to manoeuvre, when he was shut up in Richmond and Petersburg, and could not force Grant to relax his hold. Yet once more the North was filled with alarm when *Hood* crossed the Tennessee and, with Sherman far away in Georgia, threatened an invasion of Kentucky. Grant himself was on his way to take command at Nashville, when he heard the news of Thomas's crowning victory. Sherman could now present Lincoln with Savannah as a Christmas gift, and the one organized army of the Confederacy in the west was definitely broken up.

The South made a great mistake during the first winter of the war, when the North was organizing its military strength and the Confederates took no counter-measures. Their Government, counting on European recognition to be followed by peace, left *A. S. Johnston* in the west with an entirely inadequate force to hold Kentucky and Tennessee. At the first onset the Federals broke through his line of defence; his counterstroke failed; Kentucky and a great part of Tennessee were permanently lost, New Orleans fell, and the Federals gained control of great stretches of the Mississippi. Then the Confederate Government awoke from its dream. The first Conscription Act (April 1862) retained in service the 148 regiments of one-year volunteers and by encouraging voluntary enlistment enabled *Lee* to save Richmond, but the ground lost in the west was never recovered.

The Confederacy had one inherent weakness. It was composed of "sovereign" States, which would temporarily sacrifice their "State rights" for the success of their revolution, but demanded that the Central Government should provide for their protection, and if it failed in that duty, would take their own measures for self-defence. The State governors were always a thorn in *Davis's* side. From the first they required delicate handling and, when things began to go wrong, became refractory. This State patriotism combined with geographical conditions to isolate the different sections of the country and prevented the Confederates from taking proper advantage of the "interior lines." Only once did troops from the Trans-Mississippi come to the help of their countrymen on the other side of the river. *Van Dorn* moved from Arkansas to *Beauregard's* aid at Corinth, but his men were very reluctant to cross the river, and it is significant that no attempt was made to bring reinforcements to Vicksburg in 1863 from that department. Only once were considerable reinforcements sent from the east to the west, when *Longstreet* with two divisions was sent to *Bragg's* aid, and the victory of Chickamauga (*q.v.*) was the result.

The west was the really decisive theatre of war. In the east *Lee's* victories did not alter the strategical position. The end of each campaign found the Army of the Potomac on the Rappahannock, still menacing Richmond. But the fall of Vicksburg cut the Confederacy in two; the loss of the food supplies, especially cattle, from the Trans-Mississippi was sorely felt, and the capture of Chattanooga and Knoxville not only cut off another section of territory, but opened the way to Georgia, the granary of the South. That *Lee's* and *Johnston's* armies were reduced to starvation was due to the loss of Georgia's supplies. Grant indeed captured Richmond and *Lee's* army, but had he chosen he might have brought Sherman's army by sea from Savannah to the James, and it could have been there two months before he began his final move.

In final analysis the North's naval superiority must be reckoned a decisive factor. It made possible the conquest of the Mississippi and Sherman's march through Georgia. The capture of New Berne by the Burnside expedition (Mar. 1862) provided the Federal land forces with a base, from which they could threaten an advance on Richmond, and caused the permanent retention in North Carolina of a considerable Confederate force, which might have been profitably employed elsewhere, notably at the time of *Lee's* invasion of Pennsylvania. The blockade threw the South upon its own resources, which proved inadequate, especially in the matter of munitions of war and medical stores. It was not lack of food, but the difficulty of transport, which reduced the Confederate armies to the verge of starvation. The Southern railways were not equal to the strain of a four years' war. The rolling stock could not be replaced when worn out or the permanent way kept in working order owing to the lack of iron rails.

Formby, *The American Civil War* (1910). The official documents are found in *Official Records of the Union and Confederate Armies and Navies*, 130 vols. (1880-1901).

AMERICAN COLLEGE OF PHYSICIANS, an association of physicians engaged in the study and practice of internal medicine in its various branches. It was legally chartered on May 11, 1915, under the laws of the State of Delaware as a corporation "not for profit." The objects of the college as stated in the constitution are: "to uphold and maintain high standards in medical education and practice; to encourage research especially in clinical medicine; to foster measures for the prevention of disease and for improving public health; to perpetuate the history and best traditions of medicine and to maintain high standards of medical ethics; and to maintain the dignity of the profession in its relationship with patients." Its membership is made up of outstanding internists (including pediatricists, psychiatrists, neurologists, bacteriologists, pathologists, dermatologists, röntgenologists, medical teachers and investigators, tuberculosis and public health specialists) of the United States, its possessions, and Canada. Fellowship, with the degree, the designation, or the certificate of "F.A.C.P." (Fellow of the American College of Physicians), is conferred on applicants or nominees who present evidence of suitable professional qualifications and character, as specifically set forth in the constitution and by-laws of the organization.

AMERICAN COLLEGE OF SURGEONS, an American college or guild (not a teaching institution), whose fellowship embraced in 1928 approximately 8,000 qualified surgeons of North and South America. The college was organized in 1913 by some 500 surgeons of North America, leaders in every branch of surgery and representatives of all sections of the country. The object of the college is "to elevate the standard of surgery, to establish a standard of competency and of character for practitioners of surgery, to provide a method of granting fellowships in the organization, and to educate the public and the profession to

understand that the practice of surgery calls for special training, and that the surgeon elected to fellowship in this college has had such training and is properly qualified to practise surgery." The college opposes the paying of commissions for surgical work. At the annual congress and in the sectional meetings of the college, conferences are held on all matters pertaining to hospital standardization of interest to the profession, hospital personnel and the public. The "Minimum Standard" of the college sets forth definite professional requirements, essential for every hospital which aims to give the highest degree of efficiency in the professional care of its patients. Regular and special bulletins are published by the college containing information dealing with hospital standardization and the hospitals attaining to its "Minimum Standard"; and a hospital information and service bureau is maintained for the answering of questions and sending out of special data in the hospital field. *Surgery, Gynaecology and Obstetrics* is the official journal of the college. The library and department of literary research of the college were organized to further the standardization of literature on surgery and closely allied subjects and to encourage the wider reading and study of scientific material. A department of clinical research includes the committee on treatment of malignant diseases with radium and X-Ray, the committee on the treatment of fractures, the registry of bone sarcoma, the board on traumatic surgery and the committee on standardization of clinical laboratories. The most recent responsibility assumed by the college is the very extensive programme for medical motion picture films which the American College of Surgeons is fostering in co-operation with the Motion Picture Producers and Distributors of America, Inc., and the Eastman Kodak Company. A preliminary survey of films already produced is being made. For the production of additional films advisory committees have been appointed in the various branches of medicine and surgery. The headquarters of the college are in Chicago, Illinois.

AMERICAN EXCHANGE IRVING TRUST COMPANY adopted this name in 1926 when the American Exchange-Pacific Bank merged into the Irving Bank and Trust Company, at which time the capital was increased from \$22,000,000 to \$32,000,000. The Irving Bank, New York, originated in 1851 as a New York State bank under the name "New York Exchange Bank"; was chartered in 1864 as a national bank; took the name Irving National Exchange Bank of New York in 1907; changed its name to Irving National Bank, New York, in 1912; and was again converted into a New York State bank on Jan. 6, 1923, under the name Irving Bank, New York. In 1923 the Irving Bank merged into the Columbia Trust Company (formed in 1871) which then increased its capital from \$5,000,000 to \$17,500,000 and changed its name to Irving Bank-Columbia Trust Company. Three years later (1926) the National Butchers' and Drovers' Bank of the City of New York merged into the Irving Bank-Columbia Trust Company, which thereupon increased its capital to \$22,000,000 and adopted a new name, Irving Bank and Trust Company. The American Exchange-Pacific Bank had its origin in 1838 as a New York State bank, under the name American Exchange Bank. It was chartered as a national bank in 1865, under the name American Exchange National Bank, and changed its name to American Exchange-Pacific National Bank in 1925, when the Pacific Bank, a New York State institution, was converted into a national bank and merged with it. It was again converted into a New York State bank in 1928, and in 1929 resumed the name Irving Trust Company.

At the close of 1927 the total assets of the American Exchange Irving Trust Company were \$734,821,545. It is a member of the Federal Reserve System.

AMERICAN FARM BUREAU FEDERATION, an agricultural organization founded in 1919 as an outgrowth of the county farm bureau movement. County bureaux, voluntary societies of farmers, had for some years co-operated with county agricultural agents (advisers), often paying part of the agent's salary. The bureaux had gradually undertaken other activities, such as co-operative buying and selling. State farm bureau federations, with the county bureaux as units, had been formed in a

number of States. Delegates from 31 States joined in organizing the national federation, with the aim of developing an organization that should act as spokesman for American farming as a whole. The federation early established a legal department, which presented the agricultural viewpoint in railway rate cases. The federation also opened an office in Washington in the interest of agrarian legislation. The membership of the American Farm Bureau Federation is widespread, but its greatest strength is in the Middle West.

See O. M. Kile, *The Farm Bureau Movement* (1921).

AMERICAN FEDERATION OF LABOR. The American Federation of Labor was organized in Pittsburgh, Pa., Nov. 15 1881. The 107 delegates participating represented international unions, national unions, local unions and city central bodies with a membership of 262,000.

Previous to the meeting in Pittsburgh, a number of representative labour officials met in Terre Haute, Ind., and declared that the time had arrived for a more perfect combination of labour, one that would "propagate trade union principles and impress the necessity of protective trade and labour organizations." The object was to "elevate trade unionism and obtain for the wage earners respect for their rights and that reward for their services to which they were justly entitled." Three principles were adopted by the Pittsburgh convention as a basis upon which to carry on the work of the trade union movement. These were:

- "1. A shorter workday.
- "2. To recognize neither creed, colour nor nationality.
- "3. All workmen whether mechanics or labourers are eligible to membership."

Another declaration was: "We believe the gaining of higher wages and the shorter workday to be the preliminary steps toward great and accompanying improvements in the condition of the working people."

Non-Partisan Policy.—In order to insure the safety of the organization and to avoid repeating the folly of previous national labour organizations, the convention positively "forbade any member of the legislative committee from publicly advocating the claims of any of the political parties." This was the foundation for the non-partisan political policy religiously followed from 1881.

The first convention advocated the eight-hour day; the protection of children from exploitation in industry; compulsory education; declared the script system of payment of wages instead of in lawful currency a gross imposition and downright swindle; favoured legislation giving wage earners the first lien upon property upon which they had been employed; demanded the repeal of all laws regulating wages and the number of hours in a day's work; urged that a bureau of labour statistics be created in the several States and by the Federal Government, and laws be enacted forbidding the importation of foreign labourers under contract.

All these were gained. It was through agitation by the American Federation of Labor that every State in the United States has compulsory education laws and laws protecting children. Some of the laws protecting children are far below the necessary standards, and therefore organized labour obtained the submission of an amendment to the Constitution of the United States giving Congress the power to limit, regulate and prohibit the labour of children under 18 years. It secured legislation to compensate the victims of accidents in industry; for the health, safety and comfort of workers in all industries; for sanitation; and for the elimination of convict labour competition in several of the States, a principle for whose establishment it continued vigorously agitating in all the States.

Through organized labour's influence a Federal department of labour was created. The secretary of labour is a member of the President's Cabinet, and only union men have been appointed to that position. Nearly all the States have created labour departments and free employment bureaux.

Influence on Immigration.—Through its efforts immigration has been restricted. From 1898 to 1907 more than 7,000,000 immigrants came into the United States. After the War at least

10,000,000 were anxious to enter. But restrictive laws were enacted in 1924 which limited the yearly number to 164,667 and forbade immigration of persons ineligible for citizenship.

When the American Federation of Labor was organized the length of the workday ranged from ten to 18 hours. In 1884 an appeal was made "to union men and those not under the banner of organized labour in the name of justice and humanity to concentrate their energies upon the single issue of reduction in the hours of labour." The struggle for the shorter workday was carried on until practically every union man and great numbers of the unorganized gained the eight-hour day. The American Federation of Labor always opposed the fixing of hours of labour and wages by legislation except for Federal, State, county and municipal employes. One principle has been maintained—not to ask for legislation for any purpose that can be gained through organized labour's own economic power. It reserved the right to increase wages and shorten the workday through collective bargaining between chosen representatives of the unions and the employers.

Protective laws for women were sought and obtained because of the latter's inability to organize permanently. In many States, as well as the Federal Congress, laws limiting the hours of women in gainful occupations to eight were enacted.

Hours of Labour.—The increased use of machinery, which began in the early '70s, made imperative a reduction in the hours of labour. There was no opposition to the introduction of machinery, but labour demanded that it should share in the benefits accruing from its use. An outstanding feature of the reduction in hours of labour was that as the hours were reduced wages were increased. It was declared: "Social inequality, industrial instability and injustice must increase unless the workers' real wages, the purchasing power of their wages, coupled with a continuing reduction in the number of hours making up the working day are progressed in proportion to man's increasing power of production." To accomplish this the five-day week was advocated.

The American Federation of Labor has no power not delegated to it by conventions composed of delegates from national and international unions, State federations of labour, city central bodies and local unions directly affiliated. It has 106 national and international unions, four departments, composed of trades in allied industries, 49 State federations of labour (which includes Porto Rico), 794 central bodies, 742 local department councils, 365 directly affiliated local trade and federal labour unions. There are 30,000 local unions affiliated to the national and international unions. The membership is approximately 4,000,000.

Fraternal Relations.—Since 1884 the British Trades Union Congress and the American Federation of Labor have sent fraternal delegates to each other's conventions. In later years fraternal delegates from labour movements of other nations have attended the conventions of the American Federation of Labor.

In 1915 the necessity for co-operation between the labour movements of the various countries in the western hemisphere was considered. In 1918 a meeting was held at Laredo, Texas, which permanently organized the Pan-American Federation of Labor. Other conventions of the Pan-American Federation of Labor were held in New York city in 1919, in Mexico City in 1923 and in Washington in 1927.

The American Federation of Labor publishes the *American Federationist* and *Weekly News Service*. The former is a monthly magazine with nearly 100,000 circulation and is devoted to policies of the labour movement. The *Weekly News Service* furnishes news to the publications of the national and international unions and to 300 weekly labour papers published by central bodies or individuals.

The legislative committee looks after legislation in Congress. Hostile legislation is opposed and remedial legislation is supported by the committee, which works under the direction of the president.

Labor Day, which was first suggested in 1882 by the New York City Central Labor Union, has been made a legal holiday by

the Federal Government and 48 States. Other holidays celebrated by labour are: Labor Sunday, Labor Memorial Sunday and Mother's Day. It has also favoured legislation declaring May 1 Child Health Day.

Through the efforts of the American Federation of Labor, Congress freed the seamen, granting them the right to go ashore in safe harbour.

When war threatened, the United States representatives of the various national and international unions met in Washington April 6 1917, and offered their services "to our country in every field of activity, to defend, safeguard and preserve the Republic of the United States of America against its enemies whomsoever they may be, and we call upon our fellow workers and fellow citizens in the holy name of labour, justice, freedom and humanity to devotedly and patriotically give like service." This declaration was unanimously approved by the American Federation of Labor. It later declared there should be "no peace without victory."

Other activities of the American Federation of Labor were: opposition to compulsory arbitration; demanding and securing jury trials in contempt cases; crusade against the white plague; introduction of the union label; agitation against sweating shops and abolition of tenement house labour.

The view of the federation is that strikes are growing fewer in number because collective bargaining is becoming more and more recognized. General strikes are emphatically opposed.

(W. G.)

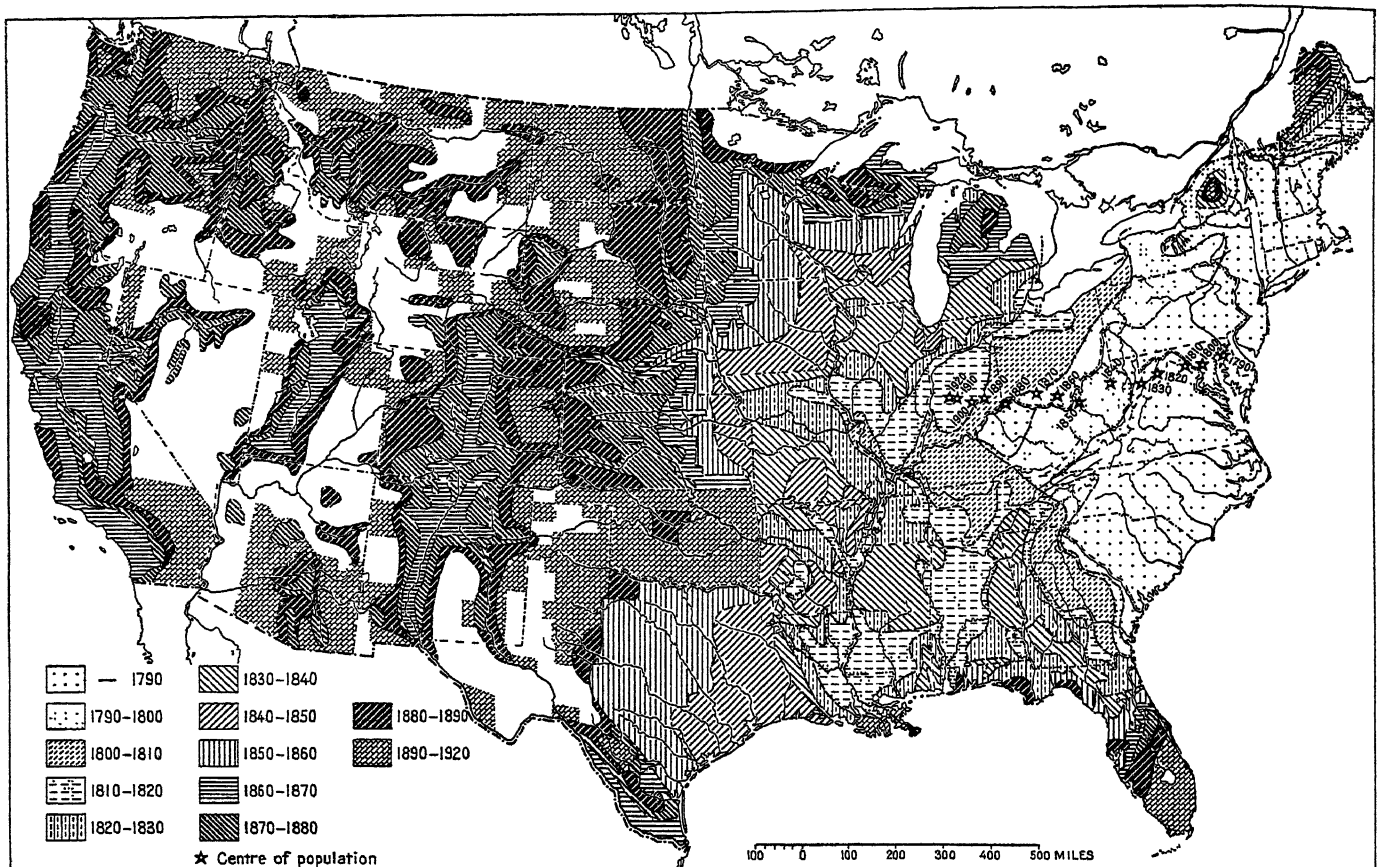

AMERICAN FRONTIER, THE. The American frontier, from an early period in the history of the continent, has affected the imagination of the pioneer who desired to exploit it, and of the visitor from afar who viewed it. Long before its existence and its significance attracted the attention of indigenous historians, it had drawn comment from the alien observer as an environment in which unusual processes were at work, and in which new human values were being born and old values were attaining new proportions. The various definitions that have been accorded it have depended largely upon the momentary use to which the frontier was being put by white men, or upon the functional relationship of the frontier as it has stood with settled society on one hand and with primitive virgin soil upon the other.

The cultural values of the frontier have come piecemeal. First, there was the explorer's frontier, as the European invader brought one geographic region after another within the field of recorded human knowledge. Next came the frontiers of the missionary, the soldier and the trapper, upon which each of these scouts of society lived his life. The first of these worked upon the souls of the native inhabitants, who were destined to recede as the world became aware of their existence; the second was staking in a new world, for one great Power or another, the claims that it was hoped one day to exploit; the third, the trapper, differed from his priestly or his military fore-runner in that he, first among white men, lived on the land he found and derived from its products a basis for existence. None of these changed the face of nature.

All gave way, eventually, when the frontier of the farmer made its appearance and dotted the land with cabins and cleared fields. There is a long succession of later frontiers that may be traced in American history, as alongside the farmer's frontier emerged also the frontiers of the miner, the lumberman and the railroad; and out of them came the frontiers of established local government, of locally created capital, of industrial society and of the various aspects of culture or religion. In each of these several fields the frontier provides a means for studying institutions while they are in the formative stage, and before they have become

MAP SHOWING THE EXPANSION OF THE AMERICAN FRONTIER EVERY 10 YEARS FROM 1790 TO 1890. THE AREAS SETTLED FROM 1890 TO 1920 ARE SHOWN COMBINED. THE MAP IS BASED ON A POPULATION OF NOT LESS THAN TWO INHABITANTS PER SQUARE MILE

inextricably involved in the complex of a progressive and sophisticated society.

From a different point of view the frontier may be described as a region, a process or a fixed line. As a region, it may be considered as a place in which the new forces of western civilized life are being applied for the first time, and in which a new social group is finding itself and is creating its internal bonds. As a process, it concerns itself with the ways and means whereby the institutions of older society are being worked over and selected according to their survival values, within the territorial limits of the frontier region. As a geographic line, it may be shown upon a map for any period at which statistical evidence is available; and in this connection it is always the line that may be drawn separating territory possessing an arbitrarily selected average of residents per square mile, from territory of less than that average number. The decennial census of the U.S. Government, since 1790, has provided the basis for this cartographic identification of the frontier. In most of the recent census reports maps are shown for each decennial period, with shadings indicating the distribution of populations of under two inhabitants per square mile, of 2 to 6, of 6 to 18, of 18 to 45, of 45 to 90 and of over 90. The steps in this scale that American historians have commonly accepted for their study of frontier lines are the first and the second. Most frontier lines are drawn at under two, or over six; and in either case the line thus drawn shows, for the period of the census concerned, the region near which the frontier process was most typically at work. A series of frontier line maps, made ten years apart, from 1790 until 1890, shows that invariably the zone of contact between settled America and the wilderness ran irregularly from north to south; and that at each decennial census it had made a perceptible advance along most of its front towards the west. At the date of the first census the line ran not far from the watershed of the Appalachians; after 1890 it had passed beyond the Great Plains, and the whole of the United States was so nearly occupied that no sharp frontier line can be indicated. The duration of the period in American history in which a frontier

line can always be shown runs, therefore, from the moment of the initial settlements in the 17th century until the close of the 19th century. To-day, there is no frontier in the true sense, and the frontier episode is closed.

The history of the frontier in America falls easily into three major divisions, that may be separated roughly by the treaties that closed the Seven Years' War (1763), and by the panic of 1837. Each of these periods has characteristics that warrant its treatment as a logical unit.

The first period is dominated by the planting and extension of the English colonies in North America. No serious damage is done by ruling out both the French and the Spanish. The French, confined mostly to the valley of the St. Lawrence, failed to develop a pioneering population; and their settlements existed chiefly as a residence for the missionaries, the military men and the trappers who were uncovering the interior of the continent without changing its aspect. The Spanish settlements in the southern portions of the United States were even less aggressive in the spreading of civilization than the French. And both French and Spanish proved themselves unable to stand up against the competition of the invaders from the British settlements.

Nature of Early Frontier.—Throughout most of the period that ran from the planting of Virginia and Massachusetts until the middle of the 18th century, the frontier in America was really a frontier of Europe, along which the institutions of the western European countries, and particularly of England, were being tested in the wilderness. This is a part of European quite as much as of American history; and every European court felt that to some extent the basis of survival among themselves was to be found among the American plantations. The period does not come to an end until, at the close of the Seven Years' War, the superior weight of the English possessions asserted itself, and it was possible for the English diplomats to claim and secure compensation by ejecting France from North America, and by pushing Spain west of the Mississippi. During the century and a half from Jamestown to the Treaty of Paris, the settlements had spread

from the beach where the earliest English colonies were planted. Up the river valleys and the bays they advanced. By 1700 they had reached and were passing the "falls line" (a line that may be shown on a map by connecting the lowest rapids or waterfalls of the successive Atlantic rivers). Beyond the "falls line" they entered the *piedmont* of the Appalachians; and by 1763 scattered areas along the upper reaches of the Mohawk, the Connecticut, the Delaware, the Susquehanna, the Potomac, the Shenandoah and the James, were alive with the activities of the pioneers. But the period preserves its unity because of the omnipresence of the European connection, because of the dependence of the settlements upon rivers flowing into the Atlantic ocean, and because the future of the continent in its relation to European suzerainty was not certain until after the expulsion of the French.

The Second Period.—The second period of the frontier in America extends from the expulsion of the French until the occupation of the Mississippi valley (that was to ripen in modern times into the Middle West); its zone stretches from the valleys of western Pennsylvania to the bend of the Missouri river, where the Kansas enters from the west. It has a striking difference from the first period for it is now an American frontier, since the new life is an offshoot from the older American establishments. In this period indeed the United States prided itself upon its aloofness from Europe and from European interests, and gave birth not only to a new breed of democracy that was identified with Andrew Jackson, but to the American system of Henry Clay, and to the international doctrine of James Monroe. The European flavour has largely disappeared, and no considerable body of new European settlers takes a part during this second period in the movement towards the West.

The Third Period.—There is a common quality in the first and second periods of frontier extension that is lacking in the third which covers the years between the panic of 1837 and the panic of 1893. This is primitive transportation. The routes of the pioneers of the earlier periods, as they sought new homes, were those of the natural roads and trails, and the river valleys that lay in the course of the movement. Until the second period was nearly at an end there were no improvements in these natural means of transport, except here and there a fragment of stone road like the Lancaster pike or the Cumberland road (each of which, however, ran close to an improved beaten way), and once

little later the completed continental railroads put an end to pioneer traffic of the older sort, and speedily brought a conclusion to the era of the frontier. The frontiersman himself was vastly changed by these improvements in his methods of travel; while the introduction of elaborate machinery on the farm, like the reapers that spread in use on the prairies, brought capital to his aid and changed the technique of his work.

Characteristics.—In each of these three periods of frontier expansion, there are vital problems which have as yet received little treatment from the historian or the economist. First and fundamental was the relation of the settler to his piece of land; for this was generally an agrarian advance. The land economics of each region had much to do with the course of development as the frontiersmen came in; and after a region had been taken up, no set of problems was more searching than that which had to do with the escape of the frontier from the burden of land encumbrance. Second was the financial problem; varying according to region and period, but pressing in every aspect. The personnel of the advance included a low proportion of persons with enough money to be free. The others had to borrow, not only to buy their land, but to pay the costs of outfit and transportation to the new homes, and for maintenance until the new farm became self-supporting. The most rapid advance of the frontier occurred after the introduction of banking brought formal credit to the aid of the frontiersman. But interest was high and his collateral was sketchy, and it nearly always happened that the debts incurred during the hopeful period of speculative development became a burden and a curse in moments of economic depression. Third, and indispensable, was the problem of marketing the surplus that has lasted over from the frontier period into modern western agriculture. The farming communities had no means of meeting land payments or absolving debts other than that of marketing a surplus of agricultural goods. In a community wholly agricultural there was no market; and long distances and high freight rates separated every good market from the source of supply. The search for a market is thus a third of the frontiersman's fundamentals, and one that has never been permanently solved except in narrow regions where agricultural diversification could enter, or where local industrial societies grew up to consume the surplus.

As the frontiersmen met their problems certain conditions were emphasized that were not unique or new, but that were not so clearly visible in older and more complicated societies. Striking among these conditions was a trend towards equalitarianism, with its resulting consequence in social and political democracy. For the bulk of any frontier group, and during a period of years that averaged perhaps 20 in a single frontier community, nearly the whole attention of society was devoted to the primary physical tasks of reclaiming the land and erecting the dwellings. The period begins when the earliest pioneer makes his appearance; it ends, normally, when the first of the native-born children leave the home cabin to move on to a new frontier. The uniformity of activity necessary for survival placed a high premium on physical and moral virtues, and threw into the discard matters of social standing, cultivation of taste, birth and even financial status. There were few things on a frontier that could be bought; least of all personal service. With all at work each resented the occasional individual who escaped work. There was a tendency to dislike those not in step with the community. Men equal in actual status found it easy to generalize upon equality, and to resent artificial prominence. A rough and ready democracy grew up, that gave tone and character to all the frontiers that appeared and passed.

Another condition of frontier life was an unusual openness of mind in certain directions. In most settled societies of the world, personal status was so nearly fixed at birth that it was safe to assume a future without change. But to the frontiersman change was the orderly expectation of life. Within two decades the successful pioneer saw his virgin claim develop and improve, his acreage increase, his cleared fields spread, his herds multiply. He saw grow around him the roads, schools, churches, county towns and institutions of government. He saw the transition

in a while a steamboat on some of the western rivers. The successful development of the steamboat for up-river traffic, the construction of numerous canals, of which the Erie canal was first and greatest, and the building of the railroads served to introduce new tendencies in migration. The routes were materially changed, speed was quickened, and the carrying capacity of the highways grew as freights declined. The zone of occupation in the third period was west of the Mississippi bend. Across the plains and mountains to the Pacific, the overland trails guided most of the migrants in the early part of the third period. A

from Indian country to sparse farming, the progress from arbitrary territorial government to full participation by the autonomous State, the spread of the available country towards the west as the Government bought land from the Indian or took it over from Spain or Mexico. And in his mind grew an idea of progress that time has scarcely dimmed in the American mind. His community was less than usually bound to rigid classifications

AN OXWAGON TRAIN, SHOWING THE COVERED WAGONS IN WHICH THE FRONTIERSMAN TRANSPORTED HIS FAMILY AND GOODS

and was abnormally ready to look upon and accept a change. He was always a romanticist as he brooded over his future; and in public affairs this state of mind turned easily into a spirit of expansion.

A more precise consequence of his economic status was his normal tendency towards the acceptance of inflationist theories of finance. Every frontier was improved, largely, by borrowed money. Although the capitalist with ready money to use or lend was not unknown, the average pioneer citizen was obliged to borrow in order to develop his farm. He borrowed amid the enthusiastic conditions of a boom period. By a kind of auto-intoxication the frontier community magnified its hope of profits, elevated the value of its land and multiplied its probable crop. Loans were made on inflated valuations; rates of interest were promised that could never be earned. Debt was spread over the whole farm, yet it was always a matter of years before more than a small fraction of the total acreage could be made to yield. The community borrowed to build its roads and public buildings; when railroads came, the community and its people bonded themselves to subsidize the railroad. From the mixture of blind enthusiasm, lack of skill and actual fraud that accompanied frontier promotion came a situation of heavy debt at a high interest rate that reduced the community to bankruptcy when the boom was over or hard times came. On such occasions, without fail, the local response to hard times and unpayable debts was the appearance of inflationist schemes and the suggestion of stay laws to prevent the forcible collection of debts. The land banks of New England, the paper money revolt of Shay, the banking restrictions of the Jackson period, the stay laws of Kentucky, the repudiation of State debts, the demand for greenbacks and the cry for free silver in turn indicated the frontier tendency to accept inflation as a remedy. And the tendency was given profound political meaning because of the uniformity of the frontier group and the lack of capitalistic dissenters among the debtor farmers. And the directness of the American representative system gave an easy route for the translation of this discontent into party action.

Repeatedly, in every region of the United States, the frontier set-up was prepared, and the resulting community fitted into the matrix and developed towards a balanced and normal life. The process was repeated so often, and under such nearly uniform conditions, that the American frontier affords one of the few places in which it is practicable to study human affairs as in a laboratory. The experiments were staged not by premeditation but by standard

conditions that repeated themselves for many generations. Raw nature and stark human power were again and again brought together; and from their contact emerged human self-governing groups. The effect of the process, as group after group selected for its use the institutions it valued, and abandoned the customs, restrictions and institutions that seemed to have lost their meaning, was to launch American society as a whole, and to transmute the person, of whatever race, into a new type that was already known as American when Benjamin Franklin made his appearance at the courts of Europe. Its constant tendency was towards direct popular government on a representative system, towards a broadening opportunity for all in affairs political, economic or social, and towards a new status for women. Enough has already been established by the historians of the frontier to indicate that herein is the most distinctive factor in the making of the United States.

In Political Life.—The political tendency of the American frontier has been unmistakable and fairly uniform. Before the American Revolution nearly every one of the English colonies was conscious of unrest among its newer settlements; and in Pennsylvania, Virginia and North Carolina this unrest had already drifted rapidly towards open conflict. In the colonies as a group, as within the several colonies, the frontier tendency created a distrust of absenteeism in finance and government. The most convincing of the explanations of the American Revolution is that it was a frontier revolt against the long-range control that emanated from Westminster, and that it was embittered because the width of the ocean had prevented the participants on either side from realizing that frontier life had created a new race across the Atlantic. The revolution was not built upon a passion to alter the scheme of life, but on the human determination to control it. The revolutionaries stopped their work when the power of England was broken and independence was attained. The new governments erected in America were direct descendants of the old colonial establishments, only sifted and modified by the normal tendencies of the frontier.

Twenty-five years after the separation from England there came a second wave of frontier discontent with the trend of affairs, and it was Thomas Jefferson who organized and led the democratic revolt. His political followers were scattered over every State, among the young and the little; but on the frontier his name aroused enthusiasm in the average mind. His democ-

racy, more than a little derived from the French revolutionary philosophers, was instantly acceptable in a community where equality in fact was the common condition. He and his lieutenants governed the United States until their enthusiasm cooled, their youthful ideals settled into middle-aged conservatism, and until a new democracy of the Mississippi valley ranged itself behind the personality of Andrew Jackson.

In 1828 Andrew Jackson was elected president of the United States, and for a third time a frontier party took charge of American destiny. A minor revolt, but one with many re-

semblances to that of Jackson, took the government away from the Jacksonians in 1840, and placed the Whig Party in power. And 20 years later, the new Republican Party, whose enthusiasms ran highest among the newer communities of the north-western States, gained control of the government and entered upon the struggle to prevent the extension of slavery and for the maintenance of the Union, with a typical child of the frontier, Abraham Lincoln, at its head.

A generation after Lincoln, the new States of the western plains, where railway activity had promoted immigration faster than the country was able to support it, festered with discontent. And again there was the element of absenteeism, of inflation finance, of the protest of the common man against the power of the great, of the desire for a re-making of the institutions of administration and government. In this, as in the earlier revolts, there was lacking any great desire to change the basis of affairs, or to alter the philosophies of life. There was little of socialism or revolution but much of a desire to capture the organs of government and to operate them in the interest of the common people. The issue was fought in 1896, over the slogan of free silver and behind the crusading leadership of William Jennings Bryan. For once the western sequence of party creations was stopped. An embattled East resisted and prevented victory for free silver and Populism. But it was because the country had changed and the frontier had become a reminiscence rather than a living fact. No comprehension of American politics is possible without an understanding of the ways and means by which, for a century after independence, this democratic wave sequence kept alive the ideals of western democrats in protest against the rigid classifications of older and industrialized society.

The Frontier Disappears.—During the final decade of the 19th century the open frontier disappeared from the American map. During the boom years of the '80s the spread of settlements went farther and faster than was economically wise; and after 1890 there was an actual recession of the settled areas, so that there are now hundreds of counties in the western States that have fewer farming inhabitants than they had in 1890. With the completion of the continental railroads, no large area was left without easy means of contact and communication with the rest of the nation. Only three tracts remained that had not reached

BY COURTESY OF THE AMERICAN RAILWAY EXPRESS COMPANY

THE STAGE COACH, THE CHIEF MEANS OF TRANSPORTATION IN THE EARLY WEST, AFTER THE COVERED WAGONS WENT AND BEFORE THE RAILROADS CAME

the full dignity of Statehood; and these, Oklahoma, Arizona and New Mexico were admitted to the Union early in the present century.

The significance of the frontier in American life was never clearly expressed until in 1893 Frederick Jackson Turner, a professor in the University of Wisconsin and himself a child of the north-western frontier, published a monograph, "The Significance of the Frontier in American History." Thereafter, by its sheer convincing quality, Turner's idea gave a new reasonableness to American history that young historians absorbed without knowing it; and that older historians, almost without exception or protest, adopted. It forced a general restatement of American history, now that the organizing principle was recognized. And this re-

statement is still under way, making progress as new studies develop the meaning of local affairs, or as new syntheses attempt to bring together the whole of the American story.

BIBLIOGRAPHY.—A brilliant synthesis giving the frontier full recognition, but with more economic determinism in it than most frontier specialists would approve, is that of Charles and Mary Beard, *The Rise of American Civilization* (1927). There is also a comprehensive survey, with its attention generally focused upon the frontier line as it swept across the country, in F. L. Paxson, *History of the American Frontier* (1924). The initial essay of Prof. Turner is most accessible in his *Frontier in American History* (1920). C. W. Alvord, *The Mississippi Valley in British Politics* (1917), and A. P. Whitaker, *The Spanish-American Frontier* (1927), are distinguished studies of the West as a stake in European diplomacy. S. J. Buck, *The Agrarian Crusade* (1919), traces the farmer movements that are an integral part of post-frontier reactions; and there is much useful detail in C. Goodwin, *The Trans-Mississippi West* (1922).

(F. L. P.)

AMERICAN GEOGRAPHICAL SOCIETY OF NEW YORK, founded in 1852, is the oldest geographical society in the United States. Its principal activity is the publication of books, maps and a quarterly journal, the *Geographical Review*, which present the result of original research in all branches of geographical science and record work carried out in the field of exploration. The society also maintains one of the outstanding collections of maps and geographical books in America. A programme of lectures is arranged annually under the auspices of the society, which also recognizes distinguished contributions to geography by the award of medals. A special department of the society's research staff is devoting itself to the compilation and publication of maps and monographs relating to Hispanic America. The society also maintains a school for the training of explorers in survey methods.

AMERICAN INSTITUTE OF CO-OPERATION, an educational institution incorporated in 1925 in the District of Columbia and holding a session for a month each summer. The idea originated in 1923 in the National Co-operative Milk Producers' Federation and readily gained the support of other agricultural organizations. The purpose of the institute is to collect and disseminate accurate information on the economic, sociological and legal phases of co-operation. So far its attention has been restricted to agricultural co-operation, but it expects in the future to broaden its field. Representatives of the important agricultural co-operative associations and other farm organizations, and economists from universities and research institutions participate in the annual sessions. These are held at various universities. The proceedings, published annually under the title *American Co-operation*, constitute a valuable compendium of principles, practices and ideals maintained in the co-operative movement in the United States.

AMERICANISM, a term first used by John Witherspoon, president of Princeton university, in 1781, designates (a) any word or combination of words which, taken into the English language in the United States, has not gained acceptance in England, or, if accepted, has retained its sense of foreignness; and (b) any word or combination of words which, becoming archaic in England, has continued in good usage in the United States. The first class is the larger and has the longer history. The earliest settlers in Virginia and New England, confronted by plants and animals that were unfamiliar to them, either borrowed the Indian names or invented names of their own.

Examples are afforded by *raccoon* (1608), *chinkapin* (1608), *opossum* (1610) and *squash* (1642) among Indian words, and by *bull-frog*, *canvasback*, *cat-bird* and *live-oak* among inventions. The former tended to take anglicized forms. Thus the Indian *isquontersquash* (at least, that is how the early chroniclers recorded it) became *squantersquash* and was then reduced to *squash*, and *otchock* became *woodchuck*. Many other words came in as the pioneers gained familiarity with the Indian life. Such words as *hominy*, *moccasin*, *pone*, *tapioca* and *succotash* remain everyday Americanisms.

The archaisms, of course, showed themselves more slowly. They had to go out of use in England before their survival in America was noticeable. But by the beginning of the 18th century there was already a considerable body of them, and all

through that century they increased. The English language in Great Britain, chiefly under the influence of pedantry in the age of Anne, was changing rapidly, but in America it was holding to its old forms. There was very little fresh emigration to the Colonies, and their own people seldom visited England. Thus by the end of the century "*I guess*" was already an Americanism, though it had been in almost universal use in England in Shakespeare's day. So, too, with many other verbs: *to wilt*, *to whittle*, *to fellowship* and *to approbate*; and with not a few adjectives: *burly*, *catty-cornered*, *likely* and *clever* (in the sense of amiable); and with multitudes of nouns: *cesspool*, *greenhorn*, *cordwood*, *jeans*, *flap-jack*, *bay-window*, *swingle-tree*, *muss* (in the sense of a row), *stock* (for cattle) and *fall* (for autumn). A few of these archaisms, in late years, have been taken back into English usage by the force of American example.

Meanwhile, American English had begun to borrow words, chiefly nouns, from the non-English settlers, and to develop many new words of its own. To the former class the Dutch contributed *cruller*, *cold-slaw*, *cookie*, *scow*, *boss*, *smearcase* and *Santa Claus*, and the French contributed *gopher*, *prairie*, *chowder*, *carry-all* and *bureau* (a chest of drawers). Other contributions came from the Germans of Pennsylvania, the Spaniards of the south-west and negro slaves. The native coinages were large in number, and full of boldness and novelty. To this period belong, for example, *backwoods*, *hoe-cake*, *pop-corn*, *land-slide*, *shell-road*, *half-breed*, *hired-girl*, *spelling-bee*, *moss-back*, *crazy-quilt*, *stamping-ground* and *cat-boat*. These words were all made of the common materials of English, but there was something in them that was redolent of a pioneer people and a new world. In their coinage the elegances were disdained; the thing aimed at was simply vividness. At the same time, verbs were made out of nouns, nouns out of verbs and adjectives out of both.

In 1789 Benjamin Franklin, who had lived in England, denounced *to advocate*, *to progress* and *to oppose* as barbarisms, but all of them are good American to-day, and even good English. Noah Webster, the lexicographer, gave his imprimatur to *to appreciate* (in value); *to eventuate* was popularized by Gouverneur Morris; and no less a hero than Washington is said to have launched to *derange*. Many inventions of that daring era have succumbed to pedagogical criticism, e.g., *to happify*, *to compromit* and *to homologize*. But others equally harsh have gradually gained acceptance, e.g., *to placate* and *to deputize*. And with them have come in a vast number of characteristic American nouns, e.g., *breadstuffs*, *mileage*, *balance* (in the sense of remainder) and *elevator* (a place for storing grain).

Divergent Meanings of Words.—It was during the same period that a number of important words, in daily use, began to show different meanings in England and America. Some familiar examples are *store*, *rock*, *lumber* and *corn*. What Englishmen call a *shop* was called a *store* by Americans as early as 1770, and long before that time *corn*, in American, had come to signify, not grains in general, but only maize. The use of *rock* to designate any stone, however small, goes back still farther, and so does the use of *lumber* for *timber*. Many of these differences were produced by changes in English usage. Thus *cracker*, in England, once meant precisely what it now means in the United States. When the English abandoned it for *biscuit* the Americans stuck to *cracker*, and used *biscuit* to designate something else. How *shoe* came to be substituted in America for the English *boot* has yet to be determined. There is indeed much that remains obscure in the early history of such Americanisms. Until very lately, American philologists kept aloof from the subject, which they apparently regarded as low. Until George P. Krapp of Columbia university took it up, there was not even any serious investigation of the history of American pronunciation.

Thus the American dialect of English was firmly established by the time the Republic was well started, and in the half-century following it departed more and more from standard English. The settlement of the West, by taking large numbers of young men beyond the pale of urbane society, made for grotesque looseness in speech. Neologisms of the most extravagant sorts arose by the thousand, and many of them worked their way

back to the East. During the two decades before the Civil War everyday American became almost unintelligible to an Englishman; every English visitor marked and denounced its vagaries. It was bold and lawless in its vocabulary, careless of grammatical niceties, and further disfigured by a drawling manner of speech. The congressional debates of the time were full of its phrases; soon they were to show themselves in the national literature.

Policing the Language.—After the Civil War there was an increase of national self-consciousness, and efforts were made to police the language. Free schools multiplied in the land, and the schoolmarm revealed all her immemorial preciousness. A clan of professional grammarians arose, led by Richard Grant White; it got help from certain of the literati, including Lowell. The campaign went to great lengths. "*It is me*" was banned as barbarous, though it is perfectly sound historically; *eye-ther* was substituted in polite usage for *ee-ther*, though *ee-ther* is correct and *eye-ther* is on the part of an American an absurd affectation.

But the spirit of the language, and of the American people no less, was against such reforms. They were attacked on philological grounds by such iconoclasts as Thomas R. Lounsbury; they were reduced to vanity by the unconquerable speech habits of the folk. Under the very noses of the purists a new and vigorous American slang came into being, and simultaneously the common speech began to run amuck. That common speech is to-day almost lawless. As Ring Lardner reports it—and he reports it very accurately—it seems destined in a few generations to dispose altogether of the few inflexions that remain in English. "*Me and her woulda went*" will never, perhaps, force its way into the grammar-books, but it is used daily, or something like it, by a large part of the people of the United States, and the rest know precisely what it means.

On higher levels the language of the Americans is more decorous, but even there it is a genuinely living speech, taking in loan-words with vast hospitality and incessantly manufacturing neologisms of its own. The argot of sport enriches it almost daily. It runs to brilliantly vivid tropes. It is disdainful of grammatical pruderies. In the face of a new situation the American shows a far greater linguistic resourcefulness and daring than the Englishman. *Movie* is obviously better than *cinema*, just as *cow-catcher* is better than *plough* and *job-holder* is better than *public servant*. The English seldom devise any thing as pungent as *rubber-neck*, *ticket-scalper*, *lame-duck*, *pork-barrel*, *boot-legger* or *steam-roller* (in its political sense). Such exhilarating novelities are produced in the United States every day, and large numbers of them come into universal use, and gradually take on literary dignity. They are opposed violently, but they prevail. The visiting Englishman finds them very difficult. They puzzle him even more than do American peculiarities of pronunciation.

The common vocabularies in England and the United States show important differences in the meaning of words. Here are a few examples:

American	English
ash-can	dust-bin
ash-cart	dust-cart
ashman	dustman
backyard	garden
baggage	luggage
baggage-car	luggage-van
ballast (railroad)	metal
bath-robe	dress-gown
beet	beet-root
bid (on a contract)	tender
bill-board	hoarding
brakeman	brakesman
bumper (car)	buffer
calendar (court)	cause-list
campaign (political)	canvass
can (noun)	tin
candy	sweets
car (railroad)	carriage, van or wagon
carom (billiards)	cannon
catalog (university)	calendar

<i>American</i>	<i>English</i>
checkers (game)	draughts
cheese-cloth	butter-muslin
chicken-yard	fowl-run
chief of police	chief constable
city editor (newspaper)	chief reporter
city ordinance	by-law
clipping (newspaper)	cutting
coal	coals
coal-oil	paraffin
collar-button	stud
commutation ticket	season ticket
corn	maize or Indian corn
counterfeiter	coiner
cow-catcher	plough
cracker	biscuit
crazy-bone	funny-bone
cross-tie	sleepers
crystal (watch)	watch-glass
daylight time	summer time
derby (hat)	bowler
dime novel	penny dreadful
district (political)	division
druggist	chemist
drug-store	chemist's shop
drummer	traveller
dry goods store	draper's shop
editorial (noun)	leader
elevator	lift
elevator boy	liftman
enlisted man	private soldier
express train (subway)	non-stop train
fire department	fire brigade
fish-dealer	fishmonger
floorwalker	shopwalker
fraternal order	friendly society
freight	goods
freight car	goods wagon
frog (railway)	crossing-plate
garters (men's)	sock-suspenders
gasoline	petrol
grade (railway)	gradient
grain	corn
grain broker	corn factor
groceries	stores
hardware dealer	ironmonger
headliner (vaudeville)	topliner
hodcarrier	hodman
hog-pen	piggery
hood (automobile)	bonnet
hospital (private)	nursing-home
huckster	coster (monger)
hunting	shooting
Indian	Red Indian
instalment business	credit trade
instalment plan	hire-purchase plan
internal revenue	inland revenue
janitor	caretaker
laborer	navvy
legal holiday	bank holiday
letter-box	pillar-box
letter-carrier	postman
locomotive engineer	engine driver
long-distance call	trunk call
lumber	deals
lumber-yard	timber-yard
mad	angry
molasses	treacle
notions	small wares
office-holder	public servant
orchestra (seats)	stalls
outbuildings (farm)	offices

<i>American</i>	<i>English</i>
parcels room	left-luggage room
patrolman (police)	constable
peanut	ground-nut, monkey-nut
pen point	nib
pitcher	jug
poorhouse	workhouse
postpaid	post-free
potpie	pie
prepaid	carriage-paid
press (printing)	machine
pressroom	machine-room
program (of a meeting)	agenda
public school	board-school
railroad man	railway servant
Rhine wine	hock
roadbed (railroad)	permanent way
roast (of meat)	joint
roll call	division
rooster	cock
round-trip ticket	return ticket
saloon	public-house
shirtwaist	blouse
shoe shine	boot polish
shoestring	boot-lace
sick	ill
sidewalk	footpath or pavement
sight-seeing bus	charabanc
silver (collectively)	plate
sled	sledge
soft drinks	minerals
spigot	tap
sponge (surgical)	wipe
stem-winder	keyless watch
stockholder	shareholder
stocks	shares
store fixtures	shop-fittings
street railway	tramway
street car	tramcar
suspenders (men's)	braces
switch (noun, railway)	points
switch (verb)	shunt
taxes (municipal)	rates
taxpayer (local)	ratepayer
tenderloin (beef)	under-cut or fillet
ten-pins	ninepins
thumb-tack	drawing-pin
ticket-office	booking-office
trained nurse	hospital nurse or nursing sister
transom (door)	fanlight
trolley car	tram-car
truck (vehicle)	lorry
undershirt	vest
warden (of a prison)	governor
wash-rag	face-cloth
washstand	washhand-stand
wastebasket	wastepaper-basket
witness stand	witness box

Of late the increase of travel and other intercommunication between England and America has tended to halt the differentiation of the two dialects. It was more marked, perhaps, before the World War than since. But if it ever vanishes altogether the fact will mark a victory for American.

The American "movie" floods England (and the rest of the English-speaking world) with American neologisms, but there is very little movement in the other direction. Thus the tail begins to wag the dog. How far the change has gone may be observed in Australia. There a cockneyfied pronunciation holds out, but the American vocabulary is increasingly triumphant. In Canada it long ago overcame the last vestiges of opposition.

BIBLIOGRAPHY.—There is no satisfactory dictionary of Americanisms,

The best is Richard H. Thornton's *American Glossary* (1912), but it is based wholly on written records and is thus incomplete. George Philip Krapp's *The English Language in America* (1925) is valuable to the student of American pronunciation, and contains much miscellaneous matter of interest, but there are gaps in it, and the author opposes his own evidence by arguing that English and American show few important differences. In *A Comprehensive Guide to Good English* (1927), by the same author, many Americanisms are listed, but the collection is by no means exhaustive. Many are also listed in the American edition of *The Pocket Oxford Dictionary of Current English* (1927), the American editor of which is George van Santvoord. Some valuable observations upon American pronunciation are in *The Pronunciation of Standard English in America*, by Krapp (1919), and in *A Dictionary of English Pronunciation with American Variants*, by H. E. Palmer, J. Victor Martin and F. G. Blandford (1926). An extensive bibliography is in H. L. Mencken's *The American Language*, 3rd ed. (1923). In 1925 Dr. Louise Pound, of the University of Nebraska, began the publication of a monthly, *American Speech* (Baltimore). It became a quarterly in 1927. (H. L. M.)

AMERICANIZATION. The popular use of the word Americanization, and the general acceptance in the United States of the idea it stands for, date from the early months of the World War. Long before the United States became an actual belligerent, American reactions to European hostilities had revealed the fact, long familiar to close students of the immigration problem, that the population of the United States contained vast sections of foreigners who, in spite of long residence in America, were still completely alien in sympathy, loyalty and general social and emotional affiliations. These persons were clearly thinking and feeling as Germans, Irish, English or Italians, not as Americans. Most disturbing of all was the inescapable realization that these foreign-minded elements included many naturalized American citizens, sometimes of long standing. It was perhaps a premonition that the United States must eventually become involved in the great conflict that made these facts produce such widespread consternation. The Americanization movement, therefore, as a distinct sociological phenomenon, may justly be considered a product of war conditions, though it is quite probable that in this, as in so many other cases of social movement, the war merely accelerated a change that was destined to come eventually in any case.

The objective of Americanization is nothing new. It is merely assimilation, the harmonization of alien with native elements into a homogeneous socio-political unit. The novelty lies in the method. Before the revelations of the war it had been generally assumed that assimilation took place in the United States spontaneously, without the exertion or necessity of any conscious effort on the part of anybody. The metaphor of the "melting pot" had been introduced and enthusiastically accepted to symbolize the mystical potency of the great democracy whereby peoples from every corner of the earth were fused into a harmonious and presumably admirable blend. Once this illusion was shattered it was inevitable that the American people should determine to do something about it. The Americanization movement represents a determination to accomplish by deliberate, purposeful means the indispensable assimilation which it was clear could no longer be trusted to natural, spontaneous forces. It was also characteristic of the American people that the means chosen should be organization, particularly through committees, and education. The two foremost committees, which promoted and stimulated the movement in its early phases, were the Committee for Immigrants in America and the closely related National Americanization committee. These worked in close co-operation with the Federal Bureau of Education which, through its Americanization division, published a special periodical, *Americanization*, promoted conferences and fostered the movement in various ways. The idea won immediate popularity. It became a favourite form of patriotic service, particularly after the entry of the United States into the war, for countless individuals whose available time was not engrossed by other war activities. Americanization agencies and activities in almost unlimited variety sprang up throughout the country. The unifying principle was the general educational conception of the problem. The logic was simple. These unassimilated foreign individuals lacked some of the important characteristics of genuine Americans. This was dangerous for America. Therefore they must be *taught* the missing qualities. The basic theory of Amer-

icanization at this stage of its development was that assimilation can be accomplished through an educational programme.

The deficiencies selected for correction were naturally the most conspicuous, specifically lack of mastery of the English language and of knowledge of American civics and history. These three subjects constituted the backbone of the Americanization curriculum. To them, however, were soon added many supplementary accomplishments such as millinery, cooking, social amenities and the care of babies, all treated in the American manner, and all to be attained by means of an educational régime. For this expansive programme all available educational agencies, with necessary modifications and adjustments, were mobilized and many special agencies were created. The public schools organized night schools and opened various kinds of special classes, State departments of education formed Americanization divisions, universities and city governments appointed Americanization directors, and many industrial concerns co-operated eagerly in the establishment of special classes for alien workers. A national conference on Americanization in industries was held in Boston in 1919.

Enthusiasm for Americanization persisted throughout the war period, and was prolonged into the reconstruction period, largely stimulated by the "Red Radical hysteria" which infected the country for two or three years. Gradually, however, interest diminished. One after another the subsidiary features were dropped, until Americanization became synonymous with teaching foreigners English, civics and history, and eventually English alone in many cases. This was due to several causes: first, the subsidence of war-time apprehensions themselves, and preoccupation with other matters; secondly, the tremendous decline in immigration due to war conditions and special restrictive legislation.

With the decline of the war-time attitude of extreme nationalism, many broad-minded Americans began to regard it as not only bigoted but also unwise to insist upon the complete transformation of the foreigner into the American type. They became convinced that the culture of the United States could be profitably enriched by the incorporation of some of the more admirable features of the various foreign nationalities. Attempts were made to supplant the metaphor of the melting-pot by other symbols, such as a "weaving-machine," which should suggest the harmonious combination of traits, not blended but preserved in their pristine quality. Americanization was presented as a two-sided process of give-and-take. Simultaneously, many students and practitioners of Americanization began to question whether, after all, it is possible to attain the objectives aimed at by means of an educational programme. The truth seemed to be that genuine assimilation is attained not by learning but by living. The process involved represents a prolonged and difficult reaction to a social environment much more vital, involved and inclusive than that of a class-room. So deeply did these convictions penetrate that within less than a decade after the armistice, many workers were reluctant to apply the word Americanization to the most well-conceived and constructive activities. As a result it has been customary to refer to those permanent and unemotional features of the program which still remain as "adult education of the foreign-born" (see ADULT EDUCATION), intimating that as far as the rising generation is concerned the educational phases of assimilation have been resigned to the regular public schools.

Rightly to judge these latter developments, it is necessary to comprehend clearly the process and the desirability of assimilation. On both of these points there is still considerable divergence of opinion. Some prominent thinkers, native as well as foreign, believe that assimilation in its accepted sense is not a desirable goal, but that the United States will reach its highest pinnacle by preserving many separate cultures side by side within its boundaries. Others continue to insist that assimilation is a two-way process. The outstanding trend of opinion, however, is probably toward the conclusion that assimilation is indispensable to national dignity, prosperity, and even existence, and that in a situation so complicated as that of the United States the only practicable means to that end is to accept one national culture, the American, as the norm and to insist that all foreign cultures must be sub-

merged in it. At least, one anomalous war-time development has been almost completely abandoned, viz., that of coerced naturalization, the insistence that the foreigner, whether willing or not, whether assimilated or not, must be compelled to acquire American citizenship on pain of deportation or some other penalty.

(H. P. F.)

AMERICAN LAW. Speaking in a technical sense there is no American law. Except within a field constitutionally restricted, there is no national supreme tribunal to unify legal doctrine. Neither is there a common law of the United States as a sovereign State. Each of the States has its own common law, unrestrained otherwise than by certain provisions of the Federal Constitution; and none of these necessarily tends to produce unity of law except the clause requiring that "full faith and credit shall be given in each State to the public acts, records and judicial proceedings of every other State"; a provision which does somewhat tend to unify doctrines respecting the conflict of laws. It is also possible that the decisions of the lower Federal courts that sit in every State and the decisions of the Supreme Court tend to regularize and nationalize judicial doctrine. This is true within the field of "general commercial law," in which the Supreme Court has held since 1842 that the Federal courts sitting within the several States are not bound to follow the judicial doctrines of the local courts; and have in fact been developing a national body of Federal commercial law, which the States have tended to follow, although not bound to do so. The importance of this was greater, however, before the spread of the various uniform acts which in recent decades have been prepared by the American Bar Association for adoption by all the States. These statutes illustrate the sense in which there does exist an American law,—there is a great body of judicial tradition, and a vast mass of legislation, embodying the rules and standards by which the American people, regardless of State lines, are content to guide their lives; and all this law presents broad features of unity. Indeed, nothing is more astonishing than the rapid spread of statutes, in a few years, into dozens or even scores of States—thus evidencing popular convictions nationally dominant; nothing more certain than the slower spread of a judicial doctrine that is felt to have adjusted justice to new conditions.

Of the civil law that once prevailed in territory subject to France and Spain little trace remains to-day except in Louisiana and in the variant marital community systems in seven other States.

In the sense just explained American law is marked by four periods of development.

(I.) **To 1776.**—It is a traditional judicial tenet that the colonists brought with them as a birthright, along with English political traditions and precedents, the common law; its concepts of property, liberty and justice; and such of its rules as fitted colonial conditions. They did indeed claim the general liberties of Englishmen. They did not claim or desire the common law; they had suffered too much from governmental tyranny which they deemed part and parcel of that system. All of the New England Colonies, by practice or explicitly, denied its binding character. Half a dozen of the other Colonies endeavoured to follow it from an early day. All the Colonies, however, had codes, some notably complete, that covered their essential needs, so that, at best, the common law was but a subsidiary system; and in several even this position was accorded, not to that law but to the Scriptures. Only three Colonies gave statutory recognition to the English law in the colonial period.

For these reasons, and because the colonies were isolated and imperial control slight, the 17th century, in particular, was a period of experiment and creativeness. The colonists were well aware of the proposals of reform and codification made by Lord Bacon and under the Commonwealth, and some of their codes were prepared in England by men who evidently sympathized with those proposals. Dozens of striking innovations—some of them of singularly modern semblance—were made upon the common law; some persisted into the later law—among which the most important was perhaps the recording of conveyances. For two reasons, however, the history of this period, although pro-

foundly interesting in itself, must be regarded as apart from the general legal development of the country. In the first place, because its practices were too divergent from the tradition of the common law. There were almost no law books—original, reprinted or imported; in most of the Colonies there were extremely few trained lawyers; even the chief justices were rarely lawyers; the highest courts were legislative or executive. Laymen administered a sort of natural equity. In the second place, because most of the valuable innovations were abandoned as soon as a reception of the common law began.

In the 18th century something like an independent judiciary developed. Imperial control became a reality; colonial statutes were disallowed (400 of them) for departures from established law; judicial appeals to England became steadily more numerous. A professional bar—for which there was evidently no place in the preceding century—gradually developed. Many of its leaders studied in the Inns of Court (perhaps 50 before 1760; 115 between 1760 and 1783); and to a very remarkable degree it was composed, otherwise, of graduates of American colleges. When the Revolution came it was entirely dominant, and this pre-eminence it retained for a century. This period was one of absorption of the English law, marked by the disappearance of older innovations and the development of few new ones. That it is in the truest sense an integral part of American legal evolution could be illustrated in many ways. Sufficient is a reference, in the field of procedure, to its system of courts, the most characteristic feature of which—the multiplication of local tribunals that brought justice near to every man, instead of a circuit system—has persisted (for similar reasons born of frontier conditions and self-government) to the present day; and, in substantive law, the origin of the American doctrine that in libel truth (subject indeed to commentary for which there is no room) is a defence.

The whole of colonial experience was of course continuous and so the spirit of the earlier century lived on through the later. Demonstrably, various of its positive innovations, clearly adapted to colonial conditions, persisted against the English reception. As for many innovations of omission, doubtless "mere ignorance had freed the colonies of a great mass of antiquated and useless rubbish" (32 N.H. 231), but what was once overlooked in ignorance must later have been excluded in wisdom.

(II.) **1776–1828.**—The formal adoption of the common law, after the Revolution, as the basis of American law—but in all the States, explicitly or in judicial practice, only so far as suited to American conditions—set an ideal which the next period was reasonably well to realize. The present continued to be essentially one of reception of the English law. This was inevitable. There was still no independent body of American law; the first volume of American reports was published in 1789; less than a dozen volumes were in print in 1800. When Kent was appointed to the New York bench in 1798 there were no reports of that State. "English authority," he says, "did not stand very high in these early feverish times, and this led me a hundred times to bear down opposition or shame it by exhaustive research and overwhelming authority." Free from hampering precedents, in his 25 years as judge and chancellor he not only gave form to the entire law of that State but made an unrivalled contribution to the law of the whole country. In this, his *Commentaries* (1826–30) played a large part; by universal consent they are worthy of comparison with Blackstone's. He set himself to the task of establishing the common law, and he succeeded. That he had not a reformer's spirit is shown by his sigh over "the piles of learning," "the profound logic, skilful criticism and refined distinctions," doomed to destruction by the New York statute abolishing the Rule in Shelley's Case. He did, however, reject the doctrine of market overt, extended replevin to any wrongful taking, and lauded the establishment of the lien-theory in mortgages.

Notable statutes of the period are fairly numerous; permitting grants in fee without mention of heirs; granting powers *in rem* to courts of equity; legitimizing children by subsequent marriage of their parents; abolishing entails and the Rule in Shelley's Case; abolishing primogeniture and establishing inheritance equally by all children; modifying the law of devises in favour of after-

born children and the issue of predeceased children; conferring limited liability upon corporations; providing a general law under which corporations might freely organize. Pennsylvania—"the first of civilized countries to do so"—provided in 1776 for a penitentiary; presumably under the influence of Beccaria, whose book had already been published in America and was soon to be found on the remotest frontiers. At the same time she introduced relief for insolvent debtors, and within a generation they were "scheduled out" of jail in remote western territories. New York, in 1827, made a complete revision of her statute-book, altering fundamentally the law of realty and providing a system which exists to-day in various States. Very notable also were reforms due to popular disuse, such as the dying-out of feoffments, fines and recoveries; all of which were used in colonial times and were provided for in the statutes of this period. These illustrations sufficiently indicate the experimental spirit of the time. It was not displayed in equal degree by the judiciary. Preferable to Kent's lament was the denunciation of demurrers by a contemporary farmer judge, as "an invention of the bar to prevent justice . . . a cursed cheat!"

(III.) 1828-68.—Almost as distinctly as in political history, the triumph of frontier democracy in the elections of 1828 marks the transition to a new era in the law. It is a period great for its critical spirit. Also, though individualism was the dominant notion of the contemporary world, in politics and in economics, and though the frontier influence might have been expected to exalt its influence, it is a period remarkable for its social spirit. Both judicial and legislative improvements reveal its originality. What Wigmore has said of the law of evidence could be said of other fields of law: "Partly because of the lack of treatises and reports, partly because of the tendency to question important rules and therefore to defend on grounds of principle and policy whatever could be defended, partly because of the moral obligation of the judiciary, in new communities, to vindicate by intellectual effort its right to supremacy over the bar, and partly, also, because of the advent, coincidentally, of the same rationalizing spirit which led to the reformatory legislation—this very necessity of restatement led to a finely reasoned system." Very important in this period, rivalling the influence of James Kent in the preceding, was the work of Joseph Story, who in 13 years (1832-45) published nine remarkable text-books, which in rapidly succeeding editions had a profound effect in forming American law.

Thus, in the law of evidence, "the period from 1840 to 1870 saw the enactment, in the various jurisdictions in this country, of most of the reformatory legislation which had been carried or proposed in England," and the promulgation of a body of opinions "superior (on the whole) to the judgments uttered in the native home of our law." Notable innovations were the repudiation of the merger of torts in crimes and of postponement of the civil action; repudiation of the doctrine of ancient lights (impossible in a new country); introduction of apportionability of rent; the first decisions permitting suits upon a contract by the beneficiary (now the general doctrine); the first decisions treating divorce as a proceeding *in rem* and recognizing a woman's separate domicile for purpose of divorce; notable decisions—though with precedents "from the first colonization" (Chief Justice Waite)—upholding the regulation of private business "affected with a public interest"; and the first of many decisions forbidding the malicious use of a land owner's privileges.

Many changes plainly reflect the special conditions of the country. Examples of such were the substitution of navigability for the tidal test of admiralty jurisdiction, thus adapting it to the inland seas and rivers of the country; the introduction of the doctrine of "colour of title" in adverse possession, and other minor changes in that subject due to frontier conditions; fence laws reversing the common law duties respecting trespass by animals; decisions concerning grain elevators that made novel changes in the law of bailments and confusion of goods. American deeds began to assume forms suitable to the simple descriptions and titles of the country; quitclaim deeds became primary and original conveyances; disseisees acquired the right to make conveyances. Great modifications were made in equitable doc-

trines of laches and forfeitures in specific performance of contracts for the purchase of land on instalments—modifications due to the fact that in America land has always been a subject of commerce, as Kent pointed out a century ago. The amazing persistence of benefit of clergy down to (and indeed through) this period was certainly due to the illiteracy of even prominent citizens in frontier society. A very remarkable adoption of frontier customs in this period (though mainly by statute) was that of the mining and water laws developed in western mining camps.

Even more distinctive than the work of the courts was the legislation of this period. At this time reform by statute became, and has remained, the primary characteristic of American Government and law. "The establishment of self-government on a new soil realized the idea of the people as the source of political power as it had not been realized in historic times" (Freund); and on a scale equally unique they proceeded to illustrate the dictum that democracy relies on laws rather than on men. Religious and property qualifications for voting, office-holding and jury service were swept away by the middle of the century. To these triumphs of liberalism a third was added in the creation of a public school system before the Civil War. A prelude to the use of the police power in the following period appears in the elaborate constitutional provisions, beginning before 1850, respecting banks, railroads and canals; and in statutes requiring periodical or cash payments of wages. Income taxes of the modern sense were adopted in the 1830s and '40s in six States. A great moral movement in the political field—for prohibition, anti-slavery and women's rights—and an altruistic effort on a vast scale in favour of the poor and defective marked the entire period. Exemption laws (which came down from colonial times) became general and liberal. Very notable was the appearance of the homestead (1836) and its inclusion in the exemption statutes. Save for slight vestiges, imprisonment for debt was everywhere abolished. The narrow protection in property rights accorded married women by equity was widened by statutes which have placed them on an equality with their husbands; although not until 1913 were the disabilities of coverture abolished in the last State. Judicial liberalism supplemented this legislation, e.g., in recognizing a wife's right in the society of her consort. It was recognition of woman's equal participation in the hazards and hardships of frontier life that wrote this entire chapter of the law. Children were protected against parental cruelty by imposing criminal responsibility; reformatories were established for minor delinquents—but their criminal liability was not much altered. In the law of property rules of inheritance were greatly changed in favour of parents, surviving spouses, the half-blood and illegitimate children. Heirs and next of kin became generally identical. Howsoever acquired, and whether from the paternal or maternal side, estates were made to descend in the same manner. All real estate became liable to execution and administration assets for payment of debts with few preferences. The fictions of ejectment disappeared. In this whole field, however, legislative reform has always been partial, casual and unsatisfactory. Variations from State to State remain to the present day innumerable. The distinctions between realty and personalty and between legal and equitable estates are still fundamental. The doctrines of tenure, and the devices to evade them that fill the law of future interests, remain in most States untouched except by fragmentary tinkering. Entails are still theoretically possible in various States. Shelley's Case has life in about half the States. Dumpor's Case, and others of ill repute, still pervert legal doctrine.

Equity, on the other hand, was developed with relative consistency. The erratic state of the property law still extends, however, to mortgages, which are hardly the same in any two States; although everywhere the legal incidents tend toward obsolescence. The equitable doctrine of priorities has from colonial days been fundamentally modified by the recording system. For historical reasons the spread of the equity system was delayed in various States, proceeding piecemeal by statutory grant; even Massachusetts having no complete system until 1877, nor Pennsylvania one to-day. The infiltration of equity into law, in such States, was a unique detail of American legal experiment. No American

court exercises the full jurisdiction of English courts of chancery, its administrative portions having been given to separate tribunals. The development of probate courts was a noteworthy feature of the period before the Civil War. During it, also, the equitable jurisdiction was generally entrusted to courts of double jurisdiction (in five States they still remain distinct and some others maintain distinct chancery terms). Under the codes of civil procedure which have been adopted since 1848 in many States the administrative fusion has been complete; the common law actions and the distinction between law and equity being abolished, in the sense that rights and reliefs formerly "legal" or "equitable" are all enforced in one "civil action." It is certain that under both these systems the principles of equity, enforced by judges trained primarily in the common law system, have somewhat suffered; the separate equity courts are, as a group, the strongest in the country to-day. On the other hand, not only did the adoption of the codes hasten the spread of equity throughout the country, but there is a steady and beneficent infiltration of its doctrines into law cases which must ultimately result in complete fusion and the general dominance of equity.

The adoption of these codes of civil procedure is the most remarkable feature of the third period, and on the whole, the most ambitious systematic reform yet undertaken in American law. The ideals of these codes have been only imperfectly realized. For various reasons (not the least, the hostility of the courts when the codes were first created) their construction has been hardly less balefully technical (and perhaps less certain) than the old common law system. Constant legislative tinkering increased uncertainty and resulted in monstrosities of bulk and complexity. While their fundamental reforms will doubtless never be abandoned, there has been in recent years a strong agitation for the regulation of strictly procedural matters by rules of court. As yet this movement has had slight success.

In some ways popular control in this period debased the judiciary. Of particularly evil consequence was a tendency to restrict the power of the trial judge in charging the jury, forbidding more than a bare restatement of the evidence. This remains to-day general practice. Down to 1798 all the judges were appointed by the governor or elected by the legislatures; by 1840 popular election was characteristic, and since then it has become increasingly predominant. A tendency to shorten the term of tenure sprang from democratic distrust of irresponsible authority. The powers of practically any judge to declare legislation unconstitutional and to issue injunctions have kept alive such distrust. Elective terms, however, have always been long as compared with those of other officials, and no frontier State ever made judicial tenure so short and precarious as did two of the oldest States in New England. There is decidedly an increasing tendency to-day to re-elect worthy judges and to make their salaries adequate. Few leaders of the bar can be drawn from practice by any feasible salary, unless under tenure for good behaviour; but the rising level of judicial ability and the many instances of brilliant men who have already served on the bench justify the belief that judicial competence is obtainable under the elective system. The gravest charge that can be brought against the frontier democracy of the period before the Civil War is that it greatly lowered the standards of admission to the bar.

The bench was both able—in some States, notably in the South, brilliant—and liberal. The legislatures were characterized by rationalism and enlightenment. The bar, whatever its defects, dominated the legislatures and enjoyed in general a social and political prestige far beyond that which it holds to-day. On the whole, the period is the greatest in the legal history of the country.

(IV.) 1868-1928.—The ultimate protection of private rights rests to-day upon guaranties in the Federal Constitution. No State may deprive any person "of life, liberty or property without due process of law," "deny to any person within its jurisdiction the equal protection of the laws," or "impair the obligation of contracts." The 14th Amendment of 1868, containing the first two of these provisions, has profoundly altered the rela-

tion between the State and Federal courts and distinctly marks a new period in the legal development of the country. Attempts to define due process and the police power—which is not restrained by the constitutional guaranties—have made the Federal courts the battle ground of the social legislation of the last half century that has sprung from the complex economic and industrial conditions developed since the Civil War. All important cases involving corporations (which were for decades parties to approximately half of all litigation) are also thrown into the same tribunals, for they are "persons" under these clauses and their charters are contracts with the State. And as corporations carry on most of the business and own a very large percentage of all the property in the country (Mr. Justice Field of the Supreme Court estimated it as four-fifths in 1890), the matter has immense social significance.

The establishment of unbridled democracy a century ago only slightly affected the treatment of industrial property. "For at least 60 years after the adoption of universal suffrage the tendency was all in the other direction—to legislate for the property owner rather than against him; to strengthen the powers of capital rather than diminish them. . . . The small protection given to the rights of man, as compared with that which was accorded to the rights of property, is a salient feature in the early history of every American State—and sometimes of its later history also" (Hadley). The explanation of this fact lies undoubtedly in the loose economic framework of society. Cheap land created a people of freeholders without class distinctions, among whom any man who aimed high might rise high. Radicalism, in such a society, could gain no headway. That came with the development of great urban centres and an industrialized society: the rural population was nine-tenths of the total in 1800, and little less in 1850, but less than half in 1920.

Industrial regulation of modern type began about 1870 with the railroads, and its assertion "shook the foundation of State and national politics for a generation." The subsequent increase of administrative commissions, with inquisitorial powers and free from judicial procedure and review, is perhaps the most striking phenomenon in recent legislation. There is a present tendency to standardize procedure and there seems to be developing in this way a great field of administrative law. Trade regulation, though with some history for 100 years, has only very recently increased with extraordinary rapidity; for example, pure food laws, now universal, began in 1892.

The purely legal status of the American industrial worker is unique. The exemption statutes have lessened the effectiveness of the law's remedy of damages; the 13th Amendment of the Federal Constitution, prohibiting "involuntary servitude," makes specific performance impossible, even were equity minded to try it. Yet these immunities were relatively worthless so long as the worker was unprotected against unfair agreements secured through his economic needs. The tendency is strongly toward increasing restriction upon "freedom" of contract and "right" to labour, although this has only very recently begun to overcome constitutional obstacles. As late as 1905 the Supreme Court held unconstitutional a law regulating the hours of bakers, but the case is already without vitality; it was killed by a dissenting epigram of Mr. Justice Holmes—"the 14th Amendment does not enact Mr. Herbert Spencer's Social Statics." In the field of tort nothing had been done up to 1900 beyond limitations upon the rules of fellow servant, contributory negligence, and assumption of risk, sometimes through and sometimes outside of employers' liability laws; thus leaving wholly unprovided for at least half of all industrial accidents. Since 1910, however, all the States have adopted workmen's compensation acts (first, 1902), and most of them industrial insurance acts. Social insurance, otherwise, is still incipient.

The range of other social legislation has been immense. Much is purely moralistic (against gambling, racing, cigarettes, liquor, sexual sin, etc.). The treatment of women merits, perhaps, special mention. Within the family the married woman has been placed in substantial equality with her husband. In industry the attempt to give her special protection has been a storm centre of agitation.

In general women enjoy to-day such protection and to some extent a favoured position in property and domestic relations. Divorce is in one State not allowed at all; elsewhere causes run from adultery only to a score and more, including mental cruelty and incompatibility. Such causes are in many instances a cover for mutual consent. As a State need not recognize a foreign divorce improperly obtained by or against its citizens, a woman's status might possibly be that of lawful spouse, divorcee or bigamist in different jurisdictions. Suits for breach of promise to marry and for alienation of affection (both almost exclusively brought by women) are curiosities of American law. "Common-law" marriage still exists in many States. Desertion of wife or children, a very common offence, is generally a crime and a score of States have adopted a uniform act on this subject prepared by the American Bar Association. In recent years there has been considerable eugenic legislation restraining freedom of marriage.

Defects of the System.—Dissatisfaction with the legal profession has been acute during recent decades. The bar has lost its one-time leadership because it has ceased to lead, to make a social contribution commensurate with its political pre-eminence. The judges have been forced to invalidate many legislative reforms demanded by popular opinion; but, even when free, few of them have been guided by a liberal appreciation of expanding public interests. "Most of the common law has developed in that atmosphere of indifferent neutrality which has enabled courts to be impartial but also keeps them out of touch with vital needs" (Freund). Even the intelligent layman in America rarely knows anything of law except through the newspaper. There he reads only of constitutional questions—seemingly mere matter of policy of which any man may judge and which often seem irrational; of criminal cases—which blazon all the vices of criminal procedure; of labour decisions and of injunctions—often recklessly vague and sweeping—which cause excessive irritation. Hence the discontent which precipitated 20 years ago the demand for the "recall" of judges and judicial decisions by popular vote, and for limitations upon the power of divided courts to invalidate statutes; all of which demands became law in a few states. The administration of justice is to-day the paramount problem in national life. Not only in many cities are the trial dockets filled for two to four years ahead; even in rural jurisdictions the same is sometimes true. General verdicts are the basis for repeated retrials of the facts. The reports of representative States show that a few years ago appellate decisions turned on pleadings in from 5 to 25% of all cases—and the higher number was much the nearer to the mean. Reversals for all causes are still given in a large proportion of all cases appealed. Innumerable reversals are still based, even in civil cases, upon errors that could not affect substantial rights, although this is now statutorily prohibited in about two-thirds of the states. The efforts of reformers are being directed toward strengthening the authority of the trial judge; re-establishing the original practice at common law of permitting the appellate court, even on writs of error, to render final judgment on the facts without ordering a new trial, as in appeals in equity; regulating procedure in higher courts by rules of court, as in England, in place of the legislative enactments, sometimes of infinite detail, which have been the almost exclusive system of the past and have been prolific of delay and appeals; and abolishing appellate reversals for immaterial defects. As regards the last there has become evident a marked improvement in the attitude of appellate judges. A great reform, rapidly spreading, is the declaratory judgment; 12 States have adopted since 1922 the uniform act drafted by the American Bar Association. Very recently statutes of Congress and of various States have made arbitration agreements specifically enforceable. Much has also been accomplished in expediting and cheapening the petty litigation of great urban centres by reorganizing them into appropriate branches under a simplified procedure. In more than 60 cities there are legal-aid societies which dispose of a vast amount of litigation substantially without charge. Regular courts for small claims and poor litigants are being established. In some States summary judgments are now being introduced, as in England, in debt collections, vastly relieving the congestion of trial dockets.

The non-inclusion of counsel fees in costs is universal American practice, but its importance as a handicap upon the poor and a weapon in the hand of the unscrupulous is at last being recognized.

All the evils of procedure present in civil suits exist in more aggravated form in criminal suits, with many others in addition. Homicides alone are estimated by many authorities at about 10,000 yearly. That many kinds of urban crime are an organized business seems to be unquestionable. That lawyers are essential to, when not part of, this business, prepared with every legal device to delay and evade justice for their criminal clients, is often manifest. Cases of worthless bail bonds, of criminals at large under several bonds at once, given in different cases, are notorious. Equally alarming is the actual inequality of men, rich or poor in money, before the law, in consequence of its delays; and of those rich or poor in influence in being brought before it. In 1909 President Taft declared the administration of the criminal law in all the States, with possibly "one or two exceptions" to be "a disgrace to our civilization." Frequently hundreds, sometimes thousands, of veniremen are examined before a jury is secured; usually days, sometimes months, are thus utilized. Delays in trial are even greater than in civil cases. Indictments are still found deficient in appellate courts, though here recent years have witnessed great improvement, for flaws of unbelievable triviality. The defendant is nowhere compelled to testify. Punishments for the same crime vary amazingly from State to State. In some States the jury has large discretion in fixing the punishment; in many it is judge of both the law and facts. The requirement of unanimous verdicts is universal in criminal cases.

Legislation is at present extremely active in remedying many of these evils. Eight States in 1926-27 adopted habitual-criminal acts which, among other things, impose life-imprisonment upon a defendant with a record of a small number (usually four) of earlier convictions. Minors have been given greater protection (since 1900) by greatly raising the age of criminal responsibility (to 16 or 18); and establishing special courts to deal with the younger delinquents, subjecting these to the State's guardianship somewhat as under the old doctrines of equity. In the field of punishment notable reforms have been introduced: suspended and indeterminate sentences, commutations for good behaviour and parole. But even these are perverted. Weak or calculating judges abuse the first with a leniency so excessive that it approaches immunity; the second appear plainly to be over-generous to hardened offenders; the most vicious of criminals are often paroled. The primary cause is probably politics; indubitably so in some States, where every step—whether or not an arrest shall be made, the defendant held to the grand jury, the case dismissed, the convict paroled—seems to be seriously entwined with political corruption.

For these evils, and equally for the evils in trial and appellate courts, in civil and criminal cases, which spring from a deep-rooted attitude toward litigation as a mere game of wit, there is no cure except in an increased power and awakened conscience of the bench, and a general betterment in the moral tone of the bar. At least as regards intellectual improvement much has been accomplished. The university law schools are of distinguished excellence and enjoy a high professional prestige. Higher standards of education are being enforced through requirements for admission to the bar—the American Bar Association now advocating a minimum pre-legal education of two years in college and a minimum professional training of three years in law-school—but less than a dozen States meet these standards. Disbarment is in the hands of the courts and has been far too sparingly resorted to. A few States have very recently incorporated their bars as self-governing bodies, with exclusive power over admission and discipline.

Codification, after the period of activity which began before the Civil War, temporarily ceased, but has recently begun again in a new form. Five codes of penal and of the substantive civil law, 30 codes of civil procedure and about thirty of criminal procedure are mainly the products of the earlier movement. The American Bar Association, acting with State commissioners, have prepared since 1892 43 uniform acts. Of these five in the commercial field (on negotiable instruments, warehouse receipts,

bills of lading, sales and stock transfers) have been adopted in from half to all jurisdictions. An American Law institute, in which teachers of law are dominant, is preparing a "restatement" of various branches of the substantive law and a model code of criminal procedure; all designed to promote uniformity in essential principles. The "Complete" or "Revised Statutes" that exist in every State of course merely "supplement" the unenacted law, but which of the two is in many States to-day of greater scope it would be hazardous to say. Legislative drafting bureaux (the earliest of 1890) exist in practically every State.

The impulse to codification has come from the unmanageable bulk of judicial law and the consequent uncertainty of legal knowledge. The number of volumes of American reports in 1917 was 17,000. The cases cited by the court in any volume run into hundreds and frequently into thousands, from many jurisdictions. In the five years 1909-13 there were passed by the National and State Governments 62,014 statutes; and there were rendered by the courts of last resort 65,379 decisions. The law is beyond the power of any layman to discover or to comprehend.

Very much has been wisely said on the necessity of guiding legislation and judicial decision by the functional test of social utility; but no efficient instrumentality has existed or now exists through which to supply objective evidence of the relative working of substantive legal rules. On the other hand it is expected that precisely this will be accomplished in the procedural field by the "judicial councils" which have been created since 1922 in nine States for the consistent study and improvement of judicial organization and procedure. Altogether, the immense significance of the new spirit manifest in the profession cannot be doubted. Most important of all is the fact that the revolt against unsocial law created by the labour struggle has spread to social workers, social scientists, the law school and finally even to the bar. It may well be that this spirit will prove to have inaugurated a new epoch in the law of the country.

PUBLIC LAW

The public law of the United States largely revolves around (1) the Federal system; (2) the written Constitution; and (3) the judicial construction of written Constitutions. These three elements are closely related, for the United States Supreme Court has from an early day been the final arbiter to determine the respective powers of the United States and of the States under the written Constitution of the nation; and the State courts (each within its own territory) are the final arbiters of State governmental power under the written Constitutions of the States.

The Federal System.—Plans of colonial federation were several times proposed before the period of the American Revolution. The movement that finally led to independence forced some degree of unity, and the first Continental Congress assembled in Philadelphia in 1774 was the outward symbol of unity of political action. What political direction there was of the revolutionary

movement came through the continuance of such an organization, without any formal written instrument of union, and this system was highly inefficient. It was replaced by the Articles of Confederation in 1781.

The Articles of Confederation established a loose union, with little in the way of a national Government, and with no power in that Government to raise revenue or to enforce its orders by action directed immediately to the citizens of the United States. The Confederation had authority to ask the States to act, but not to compel action either by the State or its citizens. It had power to make treaties but no power to enforce State observance of such treaties. Each State had power to impose restrictions upon trade with other States, and a State with the geographical advantages of New York was in a position to impose and did impose burdensome restrictions upon the commerce of the neighbouring States of New Jersey and Connecticut.

Such conditions could not long continue. They led to the assembling of the Federal Convention of 1787 and to the framing and adoption of the present Constitution of the United States, under which the present Government was instituted in 1789. The Constitution was framed with specific reference to the difficulties presenting themselves before its adoption. A governmental organization was set up independent of that in the States, and with power to enforce its commands directly up the citizens of the States. Large powers were conferred, the most important of which were the powers to control interstate and foreign commerce, to levy taxes and to raise Federal revenues independently of the States, and the control of foreign relations. Thus a central Government was constituted with real authority. The history of the Federal system since 1789 is to a large extent a history of the expansion of the importance and authority of the national Government under this Constitution. This expansion has been accomplished in several ways: (1) by a broadened construction of the original provisions of the Constitution of 1787; (2) by amendment of this Constitution; (3) by the development of means of transportation and communication which enormously increase the number of transactions in interstate and foreign commerce, subject to national control; (4) by the increased number of States, the larger portion of which were created out of territory belonging to the national Government.

Construction of the National Constitution.—The Constitution of the United States has been authoritatively and finally construed by the United States Supreme Court, an organ of the national Government. In substantially all matters this court determines the limits of national power on the one hand and of State power on the other. No matter how impartial such a tribunal may have sought to be, it has almost of necessity tended to favour the Government of which it is an organ. Under the chief justiceship of John Marshall (1801-35) it was an essential factor in establishing broad national authority. *McCulloch v. Maryland*, 4 Wheat. 316 (1819) determined that the nation had not only the powers expressly conferred upon its legislative, executive and judicial departments, but also all authority "appropriate" to carry such powers into execution. The Constitution uses the words "necessary and proper," but the court held that there was no need to show actual necessity in order to uphold national power. Under the chief justiceship of Roger Brooke Taney (1836-64) there was an occasional tendency in dicta of the court to regard State power as of greater importance, but no actual reduction of national power took place. In fact two of the broadest extensions of national power were made under Taney through reversals of views taken under Marshall. In one of these cases admiralty jurisdiction was extended to all navigable waters (*Genesee Chief v. Fitzburgh*, 12 How. 443, 1851). In the other the Federal courts acquired an extensive jurisdiction in corporate matters (*L.C. & C.R.R. Co. v. Letson*, 2 How. 497, 1844).

Although the powers of the national Government under the Constitution have been expanded, the Supreme Court has at the same time sought to prevent the destruction of State powers by construction. The power of the national Government to tax cannot be used as a mere cloak for regulation of child labour in the States under the guise of taxation; nor can the power to regulate

interstate commerce be used for such a purpose (*Hammer v. Dagenhart*, 247 U.S. 251, 1918; *Child Labor Tax Cases*, 259 U.S. 20, 1922). While the nation's powers have been extended, there remains a large sphere of State power upon which the nation may not encroach. No national power exists except as it is found in the terms of the written Constitution, and the United States Supreme Court can expand such powers only as they may be derived from the terms of the written Constitution. The terms of this document are broad and expansible, yet judicial construction of these terms has definite limits.

Amendment of the National Constitution.—But by constitutional amendment the terms of the written Constitution may be changed. Nineteen amendments to the Constitution of the United States have been adopted. The first 10 of these amendments are limitations upon the national Government, but in no material respect do they narrow the powers exercisable by that Government. The 11th amendment safeguards the States against suits; the 12th, with reference to the election of the president, does not affect governmental power. The 13th affirmed the judgment of war that slavery should be abolished. As now construed by the courts, the "due process of law" and "equal protection of the laws" clauses of the 14th amendment have transferred the protection of individual rights from the States to the national Government. The 15th and 19th amendments, and to some extent the 14th, limit the determination by the State as to who shall have the right to vote. The 17th, by providing for the popular election of senators, somewhat diminishes the importance of the States as units in the Federal system. The 18th amendment, by authorizing the establishment of Federal agencies for prohibition enforcement, has brought the nation into closer and more detailed contact with the daily life of the citizens of the United States. The 16th amendment gave to the national Government a new source of revenue, and made possible a system of subsidies or grants-in-aid, through which the national Government largely controls State policy as to matters not otherwise directly within Federal power.

Increased Contacts of a National Character.—In 1789 transactions in interstate commerce were few, and the means of conducting such commerce slow and cumbersome. As new agencies of commerce have developed, the Federal regulatory power has applied to them. With the transition from the horse and the stage-coach to the steamboat, the railroad, the telegraph, the telephone, the radio and the aeroplane, portions of the country once distant have been brought into closer relation, and the transactions controllable by the national Government have been infinitely multiplied. These changes have necessarily brought increased exercise of national power.

Federal regulation of interstate railroad rates and service came in 1887, and has rapidly expanded. The relations between interstate commerce and purely domestic commerce within a single State are necessarily close when both transactions are handled by the same agency. And so by legislation of 1920 and by judicial decision, the Federal Government has come largely to control the railroad rates for domestic transportation within the States, as an incident to the control of interstate commerce (*Railroad Commission of Wisconsin v. C.B. & Q.R.R.*, 257 U.S. 563, 1922). In the same manner the nation has come to control safety appliances of railroads in both interstate and domestic commerce (*Southern Railway v. United States*, 222 U.S. 20, 1911).

Congress began in 1890 the regulation of combinations in restraint of interstate commerce, and has in this field largely replaced State action. As an incident, the regulation of labour unions has largely been transferred to national jurisdiction by a recent decision of the United States Supreme Court (*Bedford Cut Stone Co. v. Journeymen Stone Cutters' Association*, 274 U.S. 73, 1927). By the expansion of the national banking system and the creation of the Federal Reserve system, the Federal Government largely controls the banking business of the country. There is now an extensive national control of industry, banking, labour, railroads and of the protection of individual rights.

These expansions of national authority are natural, and were to be expected. But they make the national system differ materially from any that could have been thought of in 1787.

Increased Number of States.—The national Government was created by a small number of States. The States were the creators of the nation. States as units in a Federal system were naturally more important when their number was 13 than when their number is 48. The influence of increased numbers becomes more important when we consider that 21 of these additional States were wholly created out of territory acquired by the nation and were never a part of the original States. These new States, forming more than half of the continental area of the country, are in a very real sense creatures rather than creators of the national Government. With the increased importance of interstate relations, State boundaries have largely become artificial lines, and national consciousness, greatly strengthened by the Civil War, has become politically dominant, since State elections in all but one State (Maine) are held upon the same day as national elections.

Yet, though the States have come to be less important politically as units in a Federal system and have lost all political status in international affairs, they have come, with increased complexity of social and economic needs, to have a heavier burden of governmental tasks than ever before. For upon them fall the burdens of administering criminal and civil justice in the daily affairs of life, and the tasks of more detailed regulation of industry, as well as the conduct of schools, the administration of charities and the protection of persons and property.

The Written Constitution.—The written Constitution is an essential element of the Federal system in the United States, for there must be some authoritative statement of the respective powers of nation and States. The written Constitution is not an essential device of State Government in the United States, but each State has from its beginning had such a Constitution. Tradition has now become so strong that a State without a written Constitution is hardly to be contemplated.

The national Constitution is a relatively brief document, as are a few of the earlier State Constitutions. But the typical State Constitution has now come to be a lengthy document, that not only organizes and imposes limitations upon the State Government, but also contains a great mass of detailed legislation. This legislative detail is frequently altered by State constitutional amendments. In theory the national Government has only such powers as are granted it by the national Constitution, and a State Government has all powers not denied it by the national Constitution and the Constitution of the State. This might naturally imply a strict construction against national powers and a liberal construction in favour of State legislative authority. But with long and detailed State Constitutions, we have the opposite result. Under broad constitutional grants of national authority, the United States Supreme Court has, from the first, been liberal in the construction of national power. Under detailed State Constitutions, hedging about the powers of State legislatures, the tendency of State courts has been toward a narrow construction of such powers.

Judicial Construction of Written Constitutions.—Some device is necessary in a Federal system to preserve the barriers between Federal and State powers. The United States Supreme Court serves as this agency. In addition it serves as the final agency in other cases for the determination of the powers of Congress under the Constitution; and the highest court of each State serves as the agency to determine the powers of its State legislature under the written Constitution of that State. The courts of both State and nation decline to pass upon certain questions that they term political, but apart from this they construe the written Constitutions of State and nation. The power of the courts to determine the constitutionality of legislation was first asserted in New Jersey in 1780, and has been generally recognized since the decision of the United States Supreme Court in *Marbury v. Madison*, 1 Cranch, 137 (1803).

The more detailed the Constitutions and the greater the tendency to exercise governmental power to meet new industrial and social needs, the more often are the courts called upon to construe written Constitutions. With numerous restrictions imposed on legislative action by constitutional texts, practically every important Federal and State legislative enactment now comes to

the courts for the determination of its validity. This gives to judicial decisions an emphasis proportionately greater than they deserve in the constitutional system of the United States, for in most cases the courts reach results not dissimilar from those in the countries where legislative determinations are final. But in the United States the courts have the last word, and this often leads to an emphasis upon the technical issues of constitutional construction, rather than upon the actual merits of legislation. Problems of constitutional construction have become increasingly important in the fields of (1) administrative law and (2) the administration of criminal law.

New economic and social problems have necessitated the delegation of wide authority to permanent Federal and State boards for various purposes, such as sanitation, regulation of public service corporations and of banking and insurance, workmen's compensation, and the grant and revocation of licenses to practise trades and professions. National and State Constitutions organize Governments into three departments, and impliedly forbid the delegation of legislative authority. The courts must answer the questions as to what are the functions of each department, and what are legislative powers that may not be delegated. Under pressure of practical need, the courts have found it possible to sustain wide delegations of rule-making power to administrative bodies, and also wide authority in such bodies to make determinations that may appear judicial in character. These results have been obtained through the construction of broad constitutional provisions, and have been wise ones, though the logical devices employed to distinguish later from earlier cases have often been amusing.

In the administration of criminal law the result has not been so satisfactory. Many constitutions contain detailed provisions regarding the grand jury, the jury, bail and the conduct of cases, and a number designate the precise words with which indictments shall terminate. These provisions promote technicality in judicial proceedings and retard progress, and although a number of Constitutions are easy to change, others are difficult if not impossible to amend. The courts cannot ignore these constitutional provisions, but must enforce them, though something is accomplished by liberal judicial construction. For example, the Constitution of Missouri requires that indictments conclude with the words "against the peace and dignity of the State." The Missouri Supreme Court at first said that the omission of the second "the" was fatal to an indictment, but later took the opposite view (*State v. Campbell*, 210 Mo. 202, 1908; *State v. Adkins*, 284 Mo. 680, 1920). But however liberal the courts may be, simplification of criminal procedure is retarded by placing regulations as to such matters in the text of the State Constitution.

The problems faced by the courts in constitutional construction are well illustrated by the developments in administrative law and in the administration of criminal law. Constitutional provisions creating three departments of Government and providing that each shall exercise separate powers are general and vague in character. A court may and does construe these provisions to permit what the present needs require, even though earlier decisions may have taken a different view. The only harm done by such action, if it is a harm, is the occasional use of bad logic in the effort to harmonize judicial decisions that are obviously not capable of reconciliation. The specific constitutional provisions as to criminal procedure do not give a court as great a latitude of construction, though even where a Constitution requires certain precise language, the courts may permit some variation of that language.

Constitutional provisions vary from the specific to the highly indefinite, but in the construction of all, the courts have some discretion. The discretion is greatest under the 14th amendment to the Constitution of the United States, which prescribes that no State shall "deprive any person of life, liberty or property without due process of law," and under similar clauses in State Constitutions. The United States Supreme Court has declined to define "due process of law," but reserves freedom of decision in each case. A minimum wage law for women deprives of due process of law and is unconstitutional (*Adkins v. Children's Hospital*,

261 U.S. 525, 1923). Laws limiting the labour of women to eight hours a day or forbidding night labour by women do not deprive of due process of law (*Miller v. Wilson*, 236 U.S. 373, 1915; *Radice v. New York*, 264 U.S. 292, 1924). The regulation of charges for rental is due process of law if in the opinion of the court an emergency exists, but is not due process of law if the court feels that the emergency has ceased (*Block v. Hirsch*, 256 U.S. 136, 1921; *Chastleton Corporation v. Sinclair*, 264 U.S. 543, 1924). A similar discretion rests with the courts in the construction and application of other indefinite provisions of State and national Constitutions. And the courts exercise a broad discretion even with respect to the constitutional provisions that appear most definite.

In American constitutional law there is a tendency to decide the specific case before the court, without affording much guidance as to the law applicable to similar cases in the future. And the constitutional law of the United States is found not so much in the texts of written Constitutions as in the judicial decisions construing such Constitutions. A distinguished French publicist has called this system "government by the judges." Whatever justification this may have, Bishop Hoadly's statement that "whoever hath an absolute authority to interpret any written or spoken laws, it is he who is truly the law-giver to all intents and purposes, and not the person who first spoke or wrote them," is peculiarly applicable to the constitutional law of State and nation in the United States. And constitutional law is the basis for the whole body of public law of State and nation.

Warren, *The Supreme Court in United States History* (3 vols., Boston, 1922); C. E. Martin, *Introduction to the Study of the American Constitution* (Los Angeles, 1925); Walter F. Dodd, *State Government* (new ed., 1928). (W. F. D.)

AMERICAN LEGION, an organization of World War veterans who served honourably in the armed forces of the United States or who, as American citizens, entered the armed forces of a government associated with the United States in the war. Organization was effected and a national charter was granted by Congress in 1919.

The membership, which stood at 759,799 in 1921, decreased to 609,407 in 1925, but rose to 719,873 in 1927, and early in 1928 reached the largest total for that time of the year in the legion's history. The legion maintains a national headquarters at Indianapolis, Ind., and publishes *The American Legion Monthly*, its official organ. Its activities have been directed effectively toward the passage of the National Defence Act (1920), the creation of the United States Veterans' bureau (1921), the appropriation of Government funds for the care of disabled veterans and the passage of bonus bills both by the Federal and State Governments in favour of those who served in the World War. A programme for the aid of war orphans was devised in 1923; and in 1925, with the aid of the public, a fund of about \$5,000,000 was raised to endow permanently the legion's child welfare and rehabilitation work. In 1927 community service was made the major objective for the year. More than 200 different kinds of activities were engaged in by the 10,000 posts. Among these activities were the erection of community centre buildings, athletic fields and airports, the fostering of educational projects, sponsoring boys' activities, giving emergency relief to flood sufferers and promoting various civic enterprises. An outstanding accomplishment was the Paris Convention of 1927, undertaken primarily to promote international friendliness. Twenty thousand legionnaires went to France, attended the meetings in Paris and visited cemeteries and battlefields. They were warmly welcomed by the Government and by the people of France, and for the first time a foreign organization was permitted to march beneath the Arc de Triomphe.

AMERICAN LITERATURE. The history of American literature is the history of the slow differentiation from the parent stock of a transplanted language and culture. Beginning as an offshoot from English literature it gradually differentiated in manner and matter as diverse experience thrust the two peoples apart, until it has finally come to be the expression of a culture greatly different from the culture of England. For a generation it was written by Englishmen resident in America; for upwards of 150 years it was written by colonials who looked overseas for inspiration and models; and only within comparatively recent times has it come wholly to disregard English example and express itself individually. Up to the year 1800 it was still frankly colonial in temper, reflecting the successive schools and styles of contemporary England, imitative, diffident and provincial. It imported its literary modes from London along with its wigs and small-clothes, having due regard however to the sober colonial proprieties and rarely following the extremes of London fashion.

In its beginnings American literature just missed being a child of the great age of Elizabeth. The splendour of Elizabethan times was already fading when the first English settlements were made; and the sober Puritans who constituted the bulk of the emigrants were men to whom that splendour was no other than the lure of the devil. In consequence the literary manner transported to the new world was Jacobean instead of Elizabethan—a mode involved and self-conscious, given a sobering cast by an absorbing theological interest, and wrought into grotesque shapes by the tempests that shook England during the days of Charles and Laud. It is this heavy Jacobean manner that was impressed on the first considerable body of writings in America; and Jacobean the colonial mind remained till well on into the next century. It put away its theological prepossessions with much reluctance, and it was only after long hesitation and with a certain provincial awkwardness that it accepted the brisker modes of Augustan England. The cultural soil proved none of the friendliest to the heroic couplet and the jaunty satire of Pope and Churchill; polite circles in Philadelphia and Boston laboured somewhat too consciously to acquire the air of a wit; nevertheless by the third quarter of the 18th century the Augustan mode had come pretty generally to prevail and a sprightly rationalism pushed aside the old Jacobean heaviness.

COLONIAL AMERICA: 1607-1765

Before 1800, it must be remembered, America was still only a strip of seacoast lying between the Appalachian mountains and the ocean, rugged and infertile in the north, with abundant harbours and streams of vast potential horse-power; and widening into broad alluvial plains in the south, congenial to agriculture and adapted to the great staples of tobacco, rice, indigo and cotton. The north tended to become mercantile and seafaring; the south developed a plantation life based on slavery; and the frontier from Maine to Georgia was agricultural, based on the small freehold tillage by the owner. The tone of polite society everywhere was markedly aristocratic, dominated by a merchant aristocracy in Boston and Philadelphia, and a landed aristocracy in New York and Virginia. The democratic spirit was of late growth, the product of decentralization and frontier individualism, and not till the period of the French Revolution did it become militantly self-conscious and set about the business of democratizing society and the national government—a movement that aroused the bitter hostility of the gentry, and gave rise to a considerable body of slashing satire.

Outside of New England the writings of the 17th century were largely occasional and the total output scanty. Literature in Virginia fittingly began with Captain John Smith, the picturesque Elizabethan adventurer, who wrote a number of travel books of great interest to antiquarians. They were: *A True Relation of such occurrences and accidents of noate as hath hapned in Virginia since the first planting of that Collony* (1608); *The Generall Historie of Virginia, New-England, and the Summer Isles* (1624); and, *The True Travels, Adventures, and Observations of Captaine John Smith* (1630). A veil of romance has been thrown about the sturdy Captain Smith by later writers and especially about

the figure of Pocahontas the heroine of Jamestown—somewhat quaintly called an Indian princess—who married one of the English settlers, went to England on a triumphal visit, and speedily became a romantic Virginia tradition. Another early Virginia book was *A True Repertory of the Wracke, and Redemption of Sir Thomas Gates Knight; upon and from the Ilands of the Bermudas: his Comming to Virginia, and the Estate of that Colonie then*, etc. (1610)—a picturesque account of an expedition that suffering shipwreck near the “still-vexed Bermoothes,” did not reach the colony till nearly a year after it set out. It was written by William Strachey, who for three years was secretary to the colony, and its vivid description of the storm is supposed to have found reflection in Shakespeare’s *The Tempest*. Another official of the colony, George Sandys, completed in Virginia his translation of Ovid’s *Metamorphoses* (1626). In 1656 John Hammond published *Leah and Rachel, or, the Two Fruitfull Sisters Virginia and Mary-Land*, which like some of the works written about early New England was a song in praise of the opportunities offered by the New World to the poverty-stricken of the Old.

In those primitive early days conditions were little calculated to encourage the production of literature in Virginia, and not till the 18th century was well advanced was the output considerable. Some attempts at writing history were made, as *The History of Virginia* (1705, 1722), by Robert Beverley, an excellent account by a native Virginian; but more individual and racy were such homely works as *The Sot-Weed Factor, or a Voyage into Maryland . . . By Eben. Cook, Gent.* (1708)—a satire by a reputed tobacco agent on the ways and institutions of the south, and especially on the sharp dealings of Quakers, done in Hudibrastic manner; and the *Westover Manuscripts* of Colonel William Byrd (1674-1744), a wealthy planter who has been generally looked upon as embodying the early type of southern gentleman. He had travelled widely, was at home amongst the London Wits and wrote with something of Addisonian ease and grace. *The History of the Dividing Line* is an entertaining account of the slovenly southern frontier and a social document of considerable importance.

From the outset conditions in New England were more favourable than in Virginia to the writing and printing of books. The Puritans settled compactly in villages, each organized as a church-congregation under the guidance of a minister; and this commanding authority of the ministry encouraged vigorous theological disputation and the making of thorny treatises on church polity and doctrine. New England Congregationalism was a departure from English Presbyterianism that required justification to critical English Puritans, and the ways of the theocracy needed explanation and defence. Caustic criticism of the Bible-Commonwealth was frequent, both in the old home and the new, and the responsible leaders were at pains to spread good reports of their great venture. Amongst the emigrant generation were numerous men who used their pens to good effect, and before they went to their graves they had produced a small library of Puritan documents. Of these much the most interesting and valuable are the journals and diaries that record informally the early history of the several plantations; amongst them are *The History of Plymouth Plantation*, by Governor William Bradford (1588-1657), begun in 1630 and continued in the form of annals for nearly a score of years; and *The History of New England*, by Governor John Winthrop (1588-1649), a journal that, beginning, as he records, on “Easter Monday, March 29, 1630. Riding at Cowes, near the Isle of Wight, in the ‘Arbella,’ a ship of 350 tons,” just at the setting out of the “Great Migration,” was continued to the year of his death—a vivid abstract and brief chronicle of the controversies and happenings of the Boston settlement. Of all the writings of early New England these two—and in particular Bradford’s *History*—are the most valuable historically and humanly, for in their homely pages is found much of the aspiration and adventure of those simple times.

Theology.—In comparison with the journals the abundant writings of the theologians—men like John Cotton (1585-1652), Thomas Shepard (1605-49), Thomas Hooker (1586-1647)—are so crabbed in style and so barren in present interest that few can

read them to-day with sympathy or understanding. The most dramatic figure amongst the theologians, and the one original thinker in early New England, was Roger Williams (1603-84), who, exiled from Massachusetts Bay for his inconveniently logical views, withdrew to Rhode Island where he established the first democratic commonwealth in America, and elaborated a complete democratic philosophy which marks him as one of the great political thinkers of the Commonwealth period. Unfortunately his writings are a heavy tangle of Hebraic tropes and the meaning is hard to come at. Even his most celebrated work, *The Bloudy Tenent of Persecution for Cause of Conscience* (1644), may well be taken for granted. Far more readable is a little book written by Nathaniel Ward (1578?-1652?), bearing the title *The Simple Cobbler of Aggawam in America, Willing to help mend his Native Country, lamentably tattered, both in the upper-Leather and sole, with all the honest stitches he can take*, etc. (1647). Ward was a caustic Jacobean lawyer-theologian and wit, who served God for a time in Massachusetts Bay and then returned to England to die. *The Simple Cobbler* was a contribution to the great debates then going forward on the settlement of England. Written in an old-fashioned style, crammed with quaint conceits and affected crotchets, and fierce in condemnation of toleration—"He that is willing to tolerate any unsound opinion, that his own may also be tolerated, will for a need hang God's Bible at the Devil's girdle"—it is the brightest bit of Renaissance English penned in America and it still amply repays reading.

With the passing of the emigrant generation a deepening note of provincialism crept into the life of New England. A petty round of duties in an isolated village world laid a blight on the creative mind, and the abundant writing came to be restricted pretty much to theology and morality. The learning of the ministers became increasingly crabbed and a generous culture disappeared. In such an environment the politer forms of letters would find little sustenance. There were attempts at verse, to be sure, poems dressed in rude homespun and dealing with prosaic themes. The poet laureate of a barren world was Michael Wigglesworth (1631-1705), a pastor and physician at Malden, who offered for the delectation of all godly readers two poems, *The Day of Doom* (1662?) and *Meat out of the Eater* (1669). The former hit the taste of the generation to a nicety and achieved an immense popularity. It is a dramatization of the Last Judgment that offered a convenient excuse to versify Calvinistic theology, and its vigorous jingle is marked by a crude strength, a bald realism and an amazing naïveté. It marks a great fall from another work written before the provincialism of the settlement had wrought its full effect. *The Tenth Muse lately Sprung up in America* (1650), by Anne Dudley Bradstreet (1613-72), wife of Governor Simon Bradstreet and daughter of Governor Thomas Dudley, has been made much of by literary historians, and perhaps rightly, for in some of her lines are faint echoes of a great age and great poetry, before both were finally destroyed by a crabbed environment.

More characteristic of a world given over to theology was the work of the ministers who threshed over the old straw year after year, inditing heavy sermons, and publishing much for the glory of God and their own reputations. Of these ambitious writers, who laboured faithfully but never learned to write beautifully, the best known were Increase Mather (1639-1723), and his son Cotton (1663-1728). Stout defenders of the theocracy in the

days of its decline, seeking to buttress the authority that was being undermined by a growing rationalism, they were arch-conservatives who suffered the sting of eventual defeat. Not important figures in the larger history of America, they were nevertheless of considerable significance in the prim little world of the New England clergy and they took themselves with all priestly seriousness. Of their abundant written work perhaps only the *Magnalia Christi Americana, or The Ecclesiastical History of New England* (1702), by Cotton Mather, is of any other than antiquarian interest, and even that is a curious jumble of fact and fiction. Other ministers fond of their quills were John Wise (1652-1725), a liberal who was greatly influential in determining the later form of Congregationalism; Thomas Prince (1687-1758), a painstaking historian and author of a *Chronological History of New England*; Jonathan Mayhew (1720-66), a forerunner of the later Unitarian movement and deeply immersed in Revolutionary politics; and Mather Byles (1707-88), a celebrated wit and admirer of Alexander Pope, who did much to encourage the domestication in New England of the English Augustan mode.

The most important book written in New England during the third generation was the *Diary* of Samuel Sewall (1652-1730), a Boston magistrate and money-lender who between the years 1674 and 1729 set down a plain account of what fell under his eye. Homely and often petty though the jottings are, they convey a feeling of authentic reality, and the mass of information about the daily life of Boston in the days of the transition from a theocracy to a royal colony is of very great value. Sewall is often called a New England Pepys, and despite the fact that the backgrounds of Puritan Boston were somewhat bleak and prosaic in comparison with Restoration London, there is enough likeness between the two men to justify the comparison. Very different is the *Journal* of Mme. Sarah Knight, a quaint narrative of a horse-back journey from Boston to New York in 1704, with crisp vignettes of odd figures and sharp comment on strange manners that came under her shrewd eyes. William Hubbard's *Narrative of the Troubles with the Indians* (1677), written in excellent plain English, is a modest classic amongst Indian tales; as is also Mary Rowlandson's *Narrative of the Captivity* (1682?). To frontier settlers who any night might be awakened by the fierce war-whoop, such authentic narratives came home with irresistible appeal and in their pages one still feels something of the anxieties of a generation living under the common fear.

From this petty world with its daily life turning on the axle of Calvinistic theology, the figure of Jonathan Edwards (1703-58) emerges with sharp angularity. The greatest of New England thinkers, he became the chief defender of Calvinism. The cardinal dogma on which that system rested was the dogma of predestination, which in turn rested on the principle of determinism; and it was in defence of this crucial point that he wrote his celebrated *Enquiry into the Modern Prevailing Notions of that Freedom of the Will which is Supposed to be Essential to Moral Agency* (1754), seeking to establish that the will is unfree and in consequence that the dogma of predestination is logically sound. Edwards was an acute metaphysician, an idealist not unlike Bishop Berkeley, and if he had been content with philosophy he must have made a great name for himself. To modern readers his hell-fire sermons, such as *Sinners in the Hands of an Angry God* and *The Justice of God displayed in the Endless Punishment of the Wicked*, offer amusing sketches of the landscape of hell; but they are very far from an adequate measure of the intellectual powers of Edwards. He exerted a profound influence on the course of 18th-century theology, but even his great powers were inadequate to defend Calvinism against the inroads of Unitarianism. After Edwards came such theologians as the rugged Samuel Hopkins (1721-1803), author of the Hopkinsian doctrine of willing to be damned for the glory of God, and the rationalistic Ezra Stiles (1727-95), president of Yale college and a dabbler in science; and with them 18th-century theology came to an end.

Benjamin Franklin.—While New England was thus listening to sermons and patching its worn dogmas, Philadelphia was becoming a cultural centre more humane than Boston, where more books were printed, and a freer and more genial society was

patronizing the theatre and newspaper and magazine, and cultivating the graces of polite society. By the middle of the century it had reached the distinction of being the chief provincial capital to which ambitious young men like Franklin turned most hopefully. The Quaker influence was tolerantly hospitable to new ideas, and the Lutheran influence that came with the hordes of German immigrants was equally hospitable; in consequence Philadelphia was spared the harsh repressions and coercive orthodoxy that discouraged the free play of mind in Massachusetts. It was in this pleasant little city that Benjamin Franklin (1706-90) lived and worked. Born in Boston of the plainest stock, he was apprenticed to his printer brother, but the future not seeming promising he removed to Philadelphia in 1723, worked at his trade, acquired wealth and influence, became interested in experiments with electricity, entered politics, was sent to England as agent of the popular party, and eventually became the representative of America at the court of George III. Franklin was one of the great Englishmen of the 18th century, an embodiment of the practical good sense, the rationalism, the humanitarian concern that marked the age. His mind was both practical and creative. He was the first American economist, a distinguished political thinker, and a fruitful social reformer. His writings were largely incidental to the activities of a busy life, yet he wrote much in many veins and on many subjects, and his position as a master of 18th-century prose is secure. To many his fame rests chiefly on *Poor Richard's Almanack* (1733-58), with its fund of pithy proverbial sayings, and the *Autobiography* (1771-89), with its prudent account of his early years; but characteristic as such things are they reveal only a small part of Franklin's rich and many-sided nature, and that rather the utilitarian than the cultural. To know him adequately one must read largely in his works, and especially in his excellent letters.

THE NEW NATION: 1765-1800

Into the provincial quiet of colonial life with its sober colonial psychology came the discords of the Revolutionary disputes, followed by six years of civil war and a harsh dismemberment of the dignified colonial society. With the expulsion of the Loyalists—often the wealthiest and most cultivated members of their communities—a new leadership appeared, vigorous and practical, drawn in large numbers from the younger merchants, who were impatient with the trade restrictions imposed by parliament and desired a larger measure of economic freedom. Then followed the shaping of the new fundamental law—the work of these same capable leaders—the setting up of the Federal Government, the irruption of Jacobin passions loosed by the French Revolution, and the emergence of political parties serving diverse interests. For a third of a century storm-clouds were in the sky, and during those tempestuous decades the colonial attitude of mind disintegrated and was superseded by a new Americanism. It was a period of political speculation worthy to be compared with the Commonwealth and Restoration periods 100 years before, marked by a sober and intelligent realism that was bent on exploring the reaches of a sound republicanism. Of necessity literature was largely in service to politics, and it is to the political writings of the times that the historian of letters turns most naturally.

A REDUCED REPRODUCTION OF THE TITLE PAGE OF THE FIRST EDITION OF "POOR RICHARD'S ALMANACK," ISSUED BY BENJAMIN FRANKLIN IN 1733

Political Writings.—The ten acrimonious years of preliminary discussion produced a group of pamphleteers who, in exploring refined legal and constitutional questions, eventually talked the country into war. Of these were Samuel Adams (1722-1803), a Boston Radical Democrat, who laboured tirelessly to bring about disunion; John Dickinson (1732-1808) of Philadelphia, a lawyer much concerned with nice constitutional questions; Joseph Galloway (1727-1803), a moderate who later turned Loyalist; and Tom Paine (1737-1809), an English Quaker, who was the stormy petrel of two revolutions, raising a tremendous clamour wherever he passed and bringing fear to many honest bosoms. Paine may be reckoned the complete epitome of the times. One of the greatest pamphleteers the English race has produced, his influence in America was enormous. His *Common Sense*, published early in 1776 some 14 months after his arrival in America, presented vividly to the mass mind the advantages of independence and very likely hastened the formal action of the Congress a few months later. To the French period belong his celebrated *Rights of Man*, one of the greatest revolutionary forces of the time, and *The Age of Reason*, a deistic attack on the Bible that brought down on his head all the *odium theologicum* of the age.

It was during the Constitutional period (1787-1800) that the abundant political speculation of the times came to ripe fruition. It was a richly creative period that can only be touched upon here. Amongst the leaders of American thought the most significant were John Adams (1735-1826), an embodiment of the English school of realism from James Harrington through Locke to Montesquieu; Alexander Hamilton (1757-1804), a disciple of Hobbes and Adam Smith; and Thomas Jefferson (1743-1826), a follower of Locke, modified by the French Physiocratic school. Adams was an ineffective party leader and never imposed his philosophy upon the rank and file; but Hamilton and Jefferson erected their views into party platforms and the great struggle between them runs through all later American history. Hamilton was a monarchist who desired a highly centralized and efficient Government, as like the English as possible, that should impose order at home and command prestige abroad. Accepting the new philosophy of *laissez faire* he was eager to turn America from agricultural to industrial channels. As secretary of the Treasury he united the business interests behind the administration by a skilful policy of tariffs, banks, funding and the like, with the result that he laid down the path over which America has since travelled. As a writer he is chiefly known by his contributions to *The Federalist* (1787-88), issued jointly by Hamilton, Madison and Jay, in defence of the new Constitution. The work has been much praised—perhaps over-praised—by historians of the Federalist school; it is a shrewd and skilful argument, and it has exerted a persistent influence on later judicial interpretations of the Constitution.

The leader of the opposition to Hamilton was Thomas Jefferson, a Virginia planter and intellectual, widely read in many fields, who to a sound knowledge of English political theory joined a pronounced sympathy for the social philosophy of the French Enlightenment. Like Franklin he was a physiocrat, discovering in agriculture the only productive labour, and rejecting Hamilton's industrial-capitalistic programme. A confirmed democrat, he feared power and hated an aggrandizing political State. He would keep government simple and responsive to the popular will. The most stimulating of all American political leaders, and the one whose hold on the affections of the plain people has been most persistent, Jefferson is a figure whose greatness can be appreciated only by students intimately acquainted with American history and American ideals. Although a voluminous writer, he left no single work of outstanding importance—with the exception of the *Declaration of Independence*—and like Franklin he is to be read chiefly in his letters. His *Notes on Virginia* and the *Autobiography* serve, somewhat inadequately to reveal the humanitarian side of his thought, and make clear why he was the spokesman of the native agrarian America that was moving towards political democracy.

The Hartford School.—In the midst of a young society thus struggling to achieve political freedom and to organize a Govern-

ment on untried principles, polite letters must be brought into subjection to the popular interests; and in consequence poetry and the essay, during the last decades of the century, were little more than echoes of the common partisan passions. The first considerable school of poetry arose at Hartford, Conn., in the '80s and '90s, where a group of bright young men aspired to catch the spirit of current English literature. The members of the group were John Trumbull (1750-1831), Timothy Dwight (1752-1817), Joel Barlow (1754-1812), Lemuel Hopkins (1750-1831) and David Humphreys (1752-1818). All but Barlow were fierce Federalists whose pens exuded a virulent satire of democracy and the "infidel" spirit of France—a hostility that Barlow repudiated after a sojourn in Paris where he gave his heart to the philosophy of the Enlightenment. In other fields than satire the work of the Hartford Wits is marked by a certain grandiose aspiration that was always thrusting up poetic lightning-rods to catch the bolts of Jove. A similar versifier, who may be conveniently grouped with the Connecticut poetasters, was Robert Treat Paine (1773-1811), a young Harvard dilettante who divided his love between poetry and the theatre, and was one of the earliest dramatic critics of the country. More significant than these New England versifiers was Philip Freneau (1752-1832), of Huguenot stock, a Princetonian, a sea-captain in the West Indian trade, an editor and a revolutionary, who wrote much virulent satire on the ways of Loyalists and Federalists, together with some lovely romantic verse that marks him as the forerunner of the romantic movement in America. Despite his inadequacies Freneau is the most important figure in American poetry before Bryant.

During these acrid times the drama was slowly getting under way in America, aided by British officers and preceding by a few years the rise of the novel. Dependent as it was upon the development of cultural centres and the patronage of polite society, the theatre must wait upon the growth of cities. Early in the 18th century English players appeared in the colonies, and in 1752-53 Hallam's London company played in Virginia. In New England the presentation of stage plays was long prohibited by law, and it was not till 1793 that Massachusetts repealed the act, thereby eliciting from Robert Treat Paine the remark, "the Vandal spirit of puritanism is prostrate in New England." The first American play performed by professional actors was *The Contrast*, by Royall Tyler (1757-1826), given in New York in 1787. The following year *The Father of an Only Child*, by William Dunlap (1766-1839), was put on the stage, and thereafter plays increased in number and in popularity, and the theatre entered on a period of modest prosperity.

Before leaving a century that was vigorously creative in many fields—however small the output of polite literature—attention must be drawn to two isolated figures whom to know is to love. Hector St. John de Crèvecoeur (1735-1813) was a cultivated Norman gentleman who after serving with the French army under Montcalm lived for a number of years in the colonies, travelled widely, took an American wife, established himself on a pleasant farm, and in 1782 published his *Letters from an American Farmer* filled with discursive comment on the relation of manners and environment in different colonies. Crèvecoeur was deeply infused with the current French philosophy, and as a humanitarian and nature lover he observed with considerable acuteness the growth of a new type of society in the western wilderness. Unfortunately the Revolutionary war brought disaster to him. His sympathies were Loyalist and the partisanship of civil strife took heavy toll of his happiness. Returning to Normandy he wrote other letters that only recently have been published under the title *Sketches of Eighteenth Century America* (1925). A kindred spirit was William Bartram (1739-1823), son of the well-known botanist John Bartram (1699-1777), who was brought up in his father's botanical garden at Philadelphia. In April 1773 he set forth on extensive travels through the south-eastern frontier, a botanizing trip that extended to nearly five years. He roved widely through South Carolina, Georgia, Florida and Alabama, noting the soils, the flora and fauna, and in particular the manners of the Indian tribes. The result was *The Travels of William Bartram*, published at Philadelphia in 1791, and a year later in Lon-

don. It was read by Coleridge who pronounced it the last book "written in the spirit of the old travellers." A gentle, kindly spirit, animated by the genial philosophy of the times, William Bartram was a man to have delighted Crèvecoeur and to have shared the enthusiasms of Jefferson.

Tyler, *A History of American Literature: 1607-1765* (2 vols., 1878), and *A Literary History of the American Revolution* (2 vols., 1897, with annotated bibliography). See also V. L. Parrington, *Main Currents in American Thought* (2 vols., 1927). Excellent brief accounts will be found in T. Stanton, *A Manual of American Literature* (1909), and W. B. Cairns, *A History of American Literature* (1912).

THE NINETEENTH CENTURY

The 19th century in America, disregarding formal chronology, was, so far as literature is concerned, the period from the close of the second war with England (1815) to the war with Spain (1898), a period cut sharply across by the Civil War (1861-65). In the decades preceding the latter struggle American letters were buoyantly romantic; in the years following they became increasingly realistic—a shift of temper that resulted from profound changes in American life that cannot be considered here.

Until 1815 American literature lingered in the twilight of the 18th century. The heroic couplet and the Addisonian essay possessed sturdy vitality, and when Robert Treat Paine died in 1811 a formal classicism was still in possession of the field. Nevertheless the sober culture of the earlier century was dying out. French thought was penetrating widely in America. The earliest romantics, from Freneau to Channing, were children of the Enlightenment, and the rise of the romantic movement in America coincided with the spread of French romantic philosophy. The movement began in Virginia with the inception of Jeffersonian democracy, and its first expression took the form of political theory. It came into literature under the influence of the English romantic movement, first through the writings of Tom Moore, and later through Scott, Wordsworth and Byron; and in the decade of the '20s the old classicism was finally abandoned.

Of the many changes that came with romanticism perhaps the most enduring was the substitution of new literary forms that appealed to a wider and more democratic reading public. The newspaper and the magazine vastly enlarged their appeal. *The Evening Post* (1802) and *The North American Review* (1815) were precursors of a notable line of periodicals that multiplied rapidly. The drama was to run an unprosperous course, but fiction was to become the commanding literary form as the century matured, engrossing much of the creative energy of American letters. The novel in America began somewhat inauspiciously with the venture in government under the new constitution. *The Power of Sympathy* (1789), by Sarah Wentworth Morton (1759-1846), was a Richardsonian study in two volumes of letters, heavily sentimental and dark with warning to incautious females who persist in flirting with a wicked world. Other lachrymose novels followed in the next decade. *Charlotte Temple* (1790), by Susannah Haswell Rowson (1762-1824), achieved a popularity so astonishing as to run to a vast number of editions, and it is still reprinted in cheap form for the curious. *The Coquette* (1797), by Hannah Webster Foster (1759-1840), won a success only a little less notable. Both works were reflections of the sentimental movement of the late 18th century, and they served to popularize that movement in America.

It was at the turn of the century that the romantic novel got under headway in the work of Charles Brockden Brown (1771-1810). A Philadelphia Quaker, Brown was deeply sympathetic with the ideals of the French Revolution, and he threw into his work all the ardour of a sanguine temperament. Between 1797 and 1801 he wrote seven novels—one in a single month and three in a twelvemonth—together with a mass of occasional work. A disciple of William Godwin and Mary Wollstonecraft, he united a vigorous rationalism to a romantic enthusiasm, suffusing the religion of reason with a warm humanitarianism. Structurally the most coherent of his works is *Wieland*, a tale of the "blood and

thunder" school; but the most characteristic is *Arthur Mervyn* with its Godwinian plot of an innocent youth in the grasp of a patron turned enemy, and its embodiment of French philosophy. In *Edgar Huntly* he turned to the frontier and opened a field that later writers were to exploit. The speed at which Brown wrote was not conducive to finished technique and his tales often degenerate into absurd posturings; but he rarely fails to create a romantic atmosphere and his dramatic effects are often excellent.

THE ROMANTIC REVOLUTION: 1815-70

With the conclusion of the War of 1812 began dynamic changes in American life and modes of thought that created a native romanticism of temper. Few periods in American experience have been so revolutionary. The rise of Jacksonian democracy, the beginnings of industrialism, the embroilment over slavery, the increasing urbanization of life, the emergence of reform movements, the two wars—these were forces more than adequate to break up the stiff soil and prepare it for the seeds of romanticism that came with every importation from Europe.

The Knickerbocker Group.—The new literary movement was begun by a group of New Yorkers who in 1807 issued a series of sketches that poked fun at the ways of the little Dutch town. Of the authors of *Salmagundi* Washington Irving (1783-1859) was to win international fame and become known as the father of 19th-century American letters. With the ease of Goldsmith joined to a love of the picturesque, he was a graceful stylist who threw a glamour over the past and transmuted life into gentle emotion. His most original work, *Knickerbocker's History of New York* (1809), bubbled with the railery of young wit. In 1815 he went to England and four years later published the *Sketch Book*, of which two sketches, "Rip Van Winkle" and "The Legend of Sleepy Hollow," speedily became American classics. For some 17 years he loitered about England and the Continent, discovering materials for other sketches, the most popular of which was the *Alhambra*. On his return in 1832 he set about exploiting the new romance of the West. *A Tour of the Prairies* (1835), and *Astoria* (1836), were the chief fruits of this new interest. Although he continued to write abundantly, Irving's creative work was done. He had outlived his audience and his later writings were less gratefully received; but the limpid prose of the *Sketch Book* and the effervescing wit of *Knickerbocker* were to survive as a permanent possession of American literature.

Associated with Irving in the writing of *Salmagundi* was a New Yorker whose literary course was to run less prosperously, but whose work is too native to be forgotten. James Kirke Paulding (1778-1860) never went abroad but chose to remain consciously provincial, a defender of America against all aliens. He was of plain stock, brought up in dire poverty entailed by the American Revolution. He joined the Irving group in New York city as a raw country boy. After a short apprenticeship he entered on the work that first brought him recognition—a series of humorous attacks on the English critics of American ways. In 1818 he published an idyllic poem, *The Backwoodsman*, and after 1823 he devoted his pen largely to writing "rational fictions," producing some 70 short stories and five novels. In the field of the short story he was a pioneer, writing some of his best tales—amongst others "Cobus Yerks"—when Hawthorne and Poe were at the beginning of their apprenticeship. Of the five novels *Königsmarke*, *The Long Finne* (1823) is the most amusing, and *The Dutchman's Fireside* (1831) is generally accounted his best. Paulding was not a finished craftsman, but he was an honest thinker and he wrote a homely vigorous prose.

FROM THE FIRST EDITION OF IRVING'S "HISTORY" KNICKERBOCKER, IRVING'S "SMALL, BRISK-LOOKING OLD GENTLEMAN" WHOSE HISTORY OF NEW YORK BEGINS WITH THE CREATION OF THE WORLD

Other members of the Knickerbocker group were Joseph Rodman Drake (1795-1820), Fitzgreen Halleck (1790-1867) and Nathaniel Parker Willis (1806-67); but they are unimportant in comparison with James Fenimore Cooper (1789-1851), a man of great creative vigour. His favourite theme was the receding wilderness, peopled with picturesque scouts and dignified Indian warriors. The "Leatherstocking Series"—five tales that trace the passage of the frontier to the western prairies and are given dramatic unity by the romantic figure of Natty Bumppo—has long been accounted his greatest achievement; but he wrote much else, in many fields. The seven years he spent in Europe opened a chasm between the 18th century gentleman and his native country that was never bridged. In a long series of studies, the best known of which are *Homeward Bound* and *Home as Found*, he gave free rein to a somewhat truculent criticism of the degeneration in manners and morals he professed to discover. In later years he showed a tendency to realism, and in such stories as *Wyandotté* and *The Littlepage Manuscripts—Satanstoe*, *The Chainbearer* and *The Redskins*—the older Cooper rivals his earlier work.

Controversy likewise filled many of the years of William Cullen Bryant (1794-1878), a transplanted Yankee, who after distinguishing himself as a poet, removed to New York city and entered upon a long and honourable career as editor of the *Evening Post*. He did much to dignify American journalism. He was an ardent Democrat and he combated the Whig programme with much skill; but journalistic fame is transitory, and Bryant is remembered only for his poetry, which is Wordsworthian in temper. A far greater figure was Herman Melville (1819-91), whose fierce satire was as incomprehensible as it was repugnant to his generation. As a young man Melville sailed on a whaling cruise to the South Seas, and the experiences following his desertion at Nukuheva were recorded in *Typee* (1846) and *Omoo* (1847). On his return he settled down as a man of letters and in ten years published nine works, but he fell into a mood of pessimism, and at his death had long been forgotten. His greatest books are *Typee*, *Mardi*, *Moby Dick* and *Pierre*. *Mardi*—a confused account of wanderings about the South Sea Islands—is a fierce satire on western civilization; *Moby Dick*—a story of the pursuit of the great white whale—is one of the great books of American literature; and *Pierre*, with its bitter irony, is a tale of incest and murder that marks the lowest depths of Melville's pessimism.

The last great figure of the New York group was Walt Whitman (1819-92). Almost exactly contemporary with Melville, he was an embodiment of the great forces that reached their climax in the '50s—uncritical optimism, faith in democracy, an equalitarian and libertarian passion. He regarded himself as a prophet of the brotherhood of man in the democratic civilization of the future; and the successive editions of *Leaves of Grass*, from 1855 on, are a commentary on life as interpreted by a child of the Enlightenment, with a transcendental faith in the goodness of man, and a robust scorn of all feudal and aristocratic cultures. The frank paganism of detail scandalized a Puritan reading public, and the bold levelling offended a genteel Victorianism. To these major sins he added that of a new and strange technique. With cool audacity he put aside the accent system of versification and sought a different music based on phrase rhythms—a system repudiated by his own generation but later developed by the school of free verse. The democratic philosophy of *Leaves of Grass* was amplified in *Democratic Vistas* (1870), and in other works such as *Specimen Days* (1882). Rejected by his own generation, Whitman has come to be reckoned the chief figure in American poetry. With Melville he was a child of the mid-century, the one embodying the glowing optimism of those buoyant times, the other driven to a bitter reaction.

Southern Writers.—Literature in the south came to its first vigorous expression with the rise of romanticism in the late '20s. William Wirt (1772-1834) was a genial transition figure, but less significant than John Pendleton Kennedy (1795-1870). Kennedy is reckoned the father of the romantic plantation tradition, and in *Swallow Barn* (1832) he wrote a delightful sketch of life amongst the Virginia gentry. In *Quodlibet* (1840) he contributed to the American political library a witty satire on Jacksonian

democracy, and in *Horse Shoe Robinson* and *Rob of the Bowl* he furthered the development of the historical novel. The work of creating a plantation tradition was carried further by John Esten Cooke (1830-86), who as a very young man wrote *The Virginia Comedians* (1854), *Henry St. John* (1859) and many lesser works in a somewhat florid strain. He delighted in portraying southern chivalry; but the wit, romance and melodrama never quite fuse and the effect is less finished than in Kennedy's work.

The genius of southern literature was Edgar Allan Poe (1809-1849). Virginian by adoption and preference, he was an isolated figure, set apart from his generation by his proud temper, the originality of his work and the severity of his standards. Poe was a refined craftsman who achieved distinction in the several fields of poetry, fiction and criticism. Historically his most noteworthy influence has been in the field of the short story. With the later popularity of that literary form his fame spread widely, and with that fame has come increasing recognition of his labours in the field of criticism.

It was in Charleston, the capital of southern fashion, that southern literature found its most congenial home. The little city was the seat of magazines like *The Southern Review*—a rival of Poe's *Southern Literary Messenger*—and it prided itself on a solid and dignified culture. The outstanding literary figure of Charleston was William Gilmore Simms (1806-70). He worked in many fields—poetry, fiction, biography, local history, politics—but his greatest love was for historical romance. The series of revolutionary tales, of which *The Partisan* (1835), *Katherine Walton* (1851) and *The Sword and the Distaff* (1853)—later entitled *Woodcraft*—are representative, is marked by a pronounced picaresque strain that lends vigour to pages otherwise inclined to be stilted and florid. Simms's best-known character is Lieutenant Porgy, who reappears in successive tales, a fat hero equally valiant as warrior and trencherman, whose pranks in *Woodcraft* make it the author's most amusing story.

New England Writers.—In New England the romantic movement followed a special course determined by the theological heritage of the Puritan. Before it could make headway the cardinal dogmas of Calvinism must lose their authority and the provincial New England mind become hospitable to new conceptions. It was the great schism in the church that prepared the way. The Unitarian movement brought to New England two fresh influences—the rationalism of England and the romanticism of Revolutionary France—to undermine the authority of the dogmas of total depravity, reprobation and election. The two characteristic phases of the theology thus revived were represented by William Ellery Channing (1780-1842) and Theodore Parker (1810-60), the former retaining a supernatural explanation of the origin and rôle of Christianity, and the latter abandoning all supernaturalism. In both, however, the creative conception was the conception of the excellence of human nature and the perfectibility of man—a conception that struck at the very foundation of Calvinism.

It was this invasion of French thought, with its humanitarian emphasis, that opened the New England mind to the appeal of social reform, with the result that the decades following 1830 were the golden age of New England humanitarianism. Under the leadership of William Lloyd Garrison (1805-79) the Abolition movement drew to its following many of the finest spirits of Massachusetts. John Greenleaf Whittier (1807-92) was the chief poet of the movement, but the young Lowell contributed some excellent verse. Other distinguished Abolitionists were Wendell Phillips (1811-84), Theodore Parker, Harriet Beecher Stowe (1812-1896), and Henry Ward Beecher (1813-87). From the same humanitarian root came the diverse experiments in communal living, as Alcott's "Fruitlands" and the better known "Brook Farm." Founded by George Ripley (1802-80), the latter is commonly reckoned an offshoot of the Transcendental movement. It was a picturesque and stimulating experiment that attracted a notable group of young men, amongst others Hawthorne, George William Curtis and Charles A. Dana. Emerson, Parker and Margaret Fuller were frequent visitors, but they never joined the group.

Out of Unitarianism came likewise the Transcendental move-

ment, essentially philosophical in temper, that rejected the sensationalism of Locke and adopted the intuitionism of the German idealistic school. The most distinguished members of a very considerable group were Ralph Waldo Emerson (1803-82) and Henry David Thoreau (1817-62), around whom must be set A. Bronson Alcott (1799-1888), Margaret Fuller (1810-50), Theodore Parker, George Ripley, Orestes Brownson (1803-76) and many others less known. The organ of the movement was the *Dial* (1840-44), edited by Margaret Fuller and later by Emerson. Transcendentalism represented the highwater mark of the New England romantic movement, the extreme reaction from the dogmatic Calvinism of earlier times.

The movement may be studied conveniently in the journals and works of Emerson and Thoreau. Lecturer, essayist and poet, Emerson embodied all the diverse idealisms of the times. In his thought the disintegrating forces released by the Enlightenment came to expression in a self-sufficing individualism that transmuted the Calvinist children of Adam into potential children of God who were called to live in harmony with their divine nature. The individual is superior to society and the State, and when he has realized his Godhood the State will cease to function. The major ideas of Emerson were elaborated in three essays that still retain their importance as prime documents for the student: *Nature* (1836), *The American Scholar* (1837) and the *Divinity School Address* (1838). In 1841 he published his first series of *Essays*, which with the *Journals* embody his most characteristic doctrines. Other collections of essays followed and in 1847 his first collection of poems.

Thoreau came more tardily to recognition. During his lifetime he was commonly regarded as no more than an echo of Emerson; but in recent years he has come to be placed on a parity with the better-known man. An extreme individualist he carried to their ultimate conclusions the premises of the Enlightenment, and in his rejection of all external compulsions he marked the farthest reach of the spiritual anarchism that derived from Godwin. The essay on *The Duty of Civil Disobedience* was a radical utterance even for those radical times. *A Week on the Concord and Merrimack Rivers* (1849) is an essay on life in New England, with discursive chat on books and philosophies; and *Walden* (1854) is a study in Transcendental economics—how life may be saved from enslavement to the daily routine.

In comparison with the Concord group the Cambridge and Boston writers have suffered in reputation with the passing years. Cultivated humanists, these latter derived largely from Europe and were less original and native. In his lifetime Henry Wadsworth Longfellow (1807-82) was reckoned the most distinguished American poet, and from *Voices of the Night* (1839) to *Evangeline* (1847), *The Courtship of Miles Standish* (1858) and *Hiawatha* (1855), he was without a rival in popularity. But after the Civil War his influence declined, and his later work, although frequently marked by a fine craftsmanship and a sober beauty, was far removed from the interests of the age. With his quiet sentiment, gentle morality and humane view of life, Longfellow was a New England Victorian with a large infusion of German romanticism.

Somewhat younger than his neighbour, James Russell Lowell (1819-91) was a man with liberal instincts in whom a certain vacillation prevented the adequate expression of a rich and generous nature. Poet, critic, essayist, scholar, editor, diplomat, he was often bewildered by the changing ideals of his age. As a young man he threw himself into the Abolition movement and contributed some excellent verse to the cause. Later he turned bookman and immersed himself in mediaeval and Renaissance literatures, pausing in his studies to write an occasional poem or essay, and to edit the *Atlantic Monthly*. From this quiet life he was drawn away on diplomatic missions, first to Madrid and later to London, and in his last years he was a distinguished figure if not an important creative writer. With Lowell may be grouped Oliver Wendell Holmes (1809-94), a brilliant talker and a genial writer of occasional poems. His most significant work is found in such chatty comment on things in general as *The Autocrat of the Breakfast Table* (1857), and in certain

poems, often satirical, like "The One-Hoss Shay" and "The Last Leaf." Here also may be grouped a notable company of Boston historians. George Bancroft (1800-91), William H. Prescott (1796-1859) and John Lothrop Motley (1814-77) contributed substantial works; but the most distinguished member of the group was Francis Parkman (1823-93).

The novelist of the New England renaissance was Nathaniel Hawthorne (1804-64). Of Salem stock, his literary career was

FROM DARLEY "COMPOSITIONS IN OUTLINE FOR HAWTHORNE'S 'SCARLET LETTER,'" 1879
HESTER PRYNNE CONFRONTING PURITANS IN "THE SCARLET LETTER"
The publication of "The Scarlet Letter" in 1850 marked a definite step in New England's growing tendency toward Romanticism. Its compelling spiritual tone and perfect prose won immediate fame for its author and placed it among American classics

dominated by the ghosts of the Salem past. A Puritan sceptic he joined in none of the great movements of his generation, beyond a casual year at Brook Farm that left him unchanged. His intellectual contacts were few and his interests were persistently introspective and analytical. He began as a writer of symbolical tales and only late turned to the longer romance. *Twice Told Tales* (1837) and *Mosses from an Old Manse* (1846) were a preparation for his greater works: *The Scarlet Letter* (1850), *The House of the Seven Gables* (1851) and *The Blithedale Romance* (1852)—a story of Brook Farm. Receiving appointment as American consul at Liverpool he passed seven years in England and Italy, the fruit of which was his longest romance, published in England as *Transformation* and in America as *The Marble Faun* (1860). After his return in 1860 he accomplished little, but his position as the greatest artist that Puritanism has given to America was secure.

THE CHANGE TO REALISM: 1870-1900

In the two decades following the Civil War, which have come to be called the Gilded Age, the intellectual outlook was greatly changed. The traditional cosmos of the theologians was disintegrating and a new scientific and sceptical attitude was spreading. Of the current scepticisms perhaps Henry Adams (1838-1918) was the completest embodiment, and the story of the disillusion of the post-war generation is set down in *The Education* (1906), to which must be added his *Mont Saint-Michel and Chartres* (1904)—an account of a strange Puritan quest for the Golden Age and one of the loveliest and most penetrating studies done by his generation of Americans.

In those turbid years polite literature, following the New England school, turned away from life to seek beauty; and from this alienation came what has been called the "genteel tradition" of letters, that forbade any serious grappling with reality. With a few notable exceptions such as Whitman and Joaquin Miller, the poets shut themselves up in their ivory towers to practise their craft on odes and sonnets and ballads. Of this somewhat ineffective school were George Henry Boker (1823-90), Bayard Taylor (1825-78), Richard Henry Stoddard (1825-1903), Edmund Clarence Stedman (1833-1908) and Thomas Bailey Aldrich (1836-1907). The most distinguished poet of the time

was a Georgian, Sidney Lanier (1842-81), one of a group of southern poets that included Henry B. Timrod (1829-67), Paul Hamilton Hayne (1830-86) and John Bannister Tabb (1845-1909). A brilliant musician, Lanier applied to the technique of verse a conception of quantitative values that he elaborated in *The Science of English Verse* (1880), and illustrated in the fresh rhythms of such poems as "The Marshes of Glynn."

But the new literature of the Gilded Age began with the appearance of the local colour school and the rise of the short story. The irruption of the frontier upon the aristocratic domain of letters was a death blow to the genteel tradition and bitterly resented by its votaries. Yet nothing could stay its advance. Beginning with Bret Harte (1839-1902) it was to spread during the next score of years till it dominated nearly all American literature. Harte was a New Yorker who went to California soon after the "gold rush" of 1849. He delighted in the romance of the mining camp and after some experimentation he wrote *The Luck of Roaring Camp*, *The Outcasts of Poker Flat*, *Tennessee's Partner* and *The Heathen Chinee*—the latter a humorous poem. They were published in 1868-69 and received with tremendous acclaim as the expression of an authentic America. The new vogue was established and the vagabond tale speedily developed into a conscious exploitation of local dialect, characters and setting—romantic at first but becoming increasingly realistic and drawing heavily on the tradition of frontier humour. It was the period of the final conquest of the West, of the slaughter of the vast buffalo herds, of the pony-express, of the last Indian fights—the final flaring up of the romance of the frontier before the frontier was to pass forever.

Against this background appeared Mark Twain (Samuel Langhorne Clemens, 1835-1910), the most original of the frontier school and the most representative writer of the Gilded Age. His audience had been prepared for him by a considerable group of whimsical humorists, including amongst others Artemus Ward (Charles Farrar Browne, 1834-67) and Petroleum V. Nasby (David Ross Locke, 1833-88). He came from a slovenly Missouri village on the banks of the great river that ran down to New Orleans, and after a few years as a Mississippi pilot he turned westward and joined the boisterous society of the Golden Gate. From such experiences he drew his materials for *Roughing It*, *Life on the Mississippi*, *Tom Sawyer*, *Huckleberry Finn*, with their rough humour, quizzical comment and flashes of imagination. Early in the '70s he settled at Hartford, Conn., underwent an unfortunate process of conventionalization, was caught in the maelstrom of the Gilded Age, turned pessimistic, and divided his latest years between the romantic hero-worship of *Joan of Arc*, and the cynicism of *The Mysterious Stranger*.

The cult of the local may perhaps be reckoned an unconscious protest against the spread of an encompassing nationalism. The later decades of the 19th century were marked by bitter struggle between two Americas, an older agrarian order with sharp sectional differentiations, and a rising capitalistic order that was subduing all America to a drab industrial pattern. The crisis in the century-long struggle came in the bitter campaign of 1896, the outcome of which was the overthrow of the agrarian hosts and the removal of the last obstacle to a consolidating nationality and a common national literature. To gather up and preserve quaint local idiosyncrasies of manners and character and dialect before they were finally submerged, became therefore the business of the local colour school. The immense popularity of the short story provided a convenient literary form, and in the last quarter of the century the local dialect story carried everything before it. In New England Sarah Orne Jewett (1849-1909) portrayed with delicate and loving touch the decayed gentility of the old towns, and Mary Wilkins Freeman (1862-) described with sombre realism humble village types and the struggle of the older New England order with a masterful industrialism. In the South Thomas Nelson Page (1853-1922), of Virginia, heightened the romantic colour of the plantation tradition; Joel Chandler Harris (1848-1908), of Georgia, in his "Uncle Remus" tales put into delightful form the folk-lore of the negro; George Washington Cable (1844-1925) portrayed the romantic Creole life of New Orleans;

Charles Egbert Craddock (Mary Noailles Murfree, 1850-1922) drew the gaunt, primitive figures of Tennessee mountaineers; Octave Thanet (Alice French, 1850-) took for her field village life in Arkansas; and Constance Fenimore Woolson (1848-94), one of the pioneers of the group, dealt with the materials of several frontiers—the West of the lake region, Florida and the Appalachian mountain recesses of Virginia, North Carolina, South Carolina and Georgia.

In the new West of the Middle Border where the prairies begin, the studies in local colour inclined less to the picturesque and more to the drab realistic. The work was begun by Edward Eggleston (1837-1902), whose *Hoosier Schoolmaster* (1871) and *The Circuit Rider* (1874) aspired to be faithful chronicles of life on the Indiana frontier. The scene thus depicted with a crude veracity was re-drawn in romantic colours in the next generation by James Whitcomb Riley (1852-1916), the poet laureate of the middle West in the days just preceding the invasion of industrialism, whose folk verse was recited at every parlour gathering for a generation. A mood of the Middle Border more akin to that of Eggleston than of Riley is revealed in the early stories of Hamlin Garland (1860-). A product of the prairie frontier from Wisconsin to North Dakota, he was caught by the spirit of rebellion that surged up in the great Populistic movement of the '80s and '90s, and in *Main Travelled Roads* (1891) and later tales, including *Rose of Dutcher's Coolly* (1895), he painted grim, realistic sketches of farm life. Garland was the first farm-bred writer to deal honestly with his materials. In his view the prairie farmer suffered from unjust exploitation at the hands of the city, and he threw himself ardently into the cause of agrarianism. After the defeat of 1896 he turned to other fields, and eventually in *The Son of the Middle Border* (1918) he wrote a lovely idyll of farm life in which the harsh colours of the earlier stories are subdued to softer tones, without losing their veracity.

While the short story was drifting uncertainly from romance to realism the novel was following the same course. Two tendencies were at work in American life during those years of transition that determined the content and form of fiction—the rise of sociology and the attitude of scientific detachment; and from these tendencies came a new type of sociological-realistic novel that dealt in a critical spirit with the political and social phenomena of the times. The new attitude was revealed in a long series of novels that, beginning with *The Gilded Age* (1873) by Mark Twain and Charles Dudley Warner (1829-1900), rose eventually to a flood that involved almost all fiction between 1903 and 1917. The conquest of American life by industrialism brought forth abundant protests, and the history of the times is written fairly adequately in those sociological studies. Albion W. Tourgee (1838-1905) dealt with reconstruction in the South in a series of novels the best known of which is *A Fool's Errand* (1879), and later portrayed socialism sympathetically in *Murvale Eastman* (1890). As a result of the political corruption of the '70s Henry Adams in *Democracy* (1880) drew pessimistic conclusions from the American experiment in government, and as an aftermath of the great strikes of the same years John Hay (1838-1905) directed a somewhat ill-natured attack on the rising labour movement in *The Bread-Winners* (1883). In 1888 Edward Bellamy (1850-98) made a wide appeal with his Marxian Utopia, *Looking Backward*, and nine years later supplemented it with *Equality*, an excellent Marxian tract in story form. In the '90s the sociological novel multiplied rapidly, preparing the way for the later "muck-raking movement" that went hand in hand with the Progressive movement in politics. To this group belonged Hjalmar Hjorth Boyesen, a transplanted Norwegian scholar, who combined in his novels keen social analysis and suggestions of the realistic technique of Zola.

The most popular novelist of the period was F. Marion Crawford (1854-1909), who lived mostly in Italy and whose influence was thrown strongly on the side of romanticism; but certainly the greatest figures were William Dean Howells (1837-1920) and Henry James (1843-1916), who were the first deliberate and conscious American realists to achieve a finished technique. Neither of them was a follower or imitator of European realism,

but each created a method that suited his individual temperament. Howells was an Ohio boy who during the Civil War immersed himself in Italian culture, and soon after his return settled in Cambridge, Mass., where his art was given shape by the "genteel tradition" of letters still regnant there. His technique developed in the late '70s and bore many of the marks of his Brahman environment—a refined craftsmanship, a lambent humour, a genial optimism, and a nice care for the truthful portrayal of externals. In his minute studies of New England manners, such as *A Modern Instance* (1882), *The Rise of Silas Lapham* (1885) and *April Hopes* (1887), the talk skims gracefully over the surface of life without revealing the deeper emotions. In the late '80s he came under the influence of Tolstoi, and this with his removal to New York brought a subtle change in mood with no corresponding change in technique. An awakening interest in social problems darkened his skies, and in *A Hazard of New Fortunes* (1889) he wrote what is probably his greatest novel. During these years he was tireless in advocacy of realism, and *Criticism and Fiction* (1891) sums up his later theory. Though he had become concerned over social problems he never adopted the current forms of sociological fiction, but chose to embody his protests against industrialism in charming Utopian romances. *A Traveller from Altruria* (1894) and *Through the Eye of the Needle* (1907) are marked by an urbanity that almost draws the sting of his criticism. Howells wrote abundantly in many forms—the travel sketch and critical comment in particular—and his total work amounts almost to a library.

The writings of Henry James touched American life only slightly, and then the world of polite manners rather than of daily actuality. An intellectual cosmopolitan, he spent much of his life in Europe, slowly drifting back to that rich civilization which his emigrant ancestors had left behind. For years he suffered from a certain cultural nostalgia, a "relish for the element of accumulation in the human picture and for the infinite superpositions of history." Always the American backgrounds seemed to him thin and unsatisfying. In his earlier years he dwelt between two worlds, but when after years of London life he found himself at last at home in the scene, his art arrived at a rich maturity in such work as *The Ambassadors* (1903). A long alienation limited his understanding of his native land, and when he essayed, as in *The Bostonians* (1886), to depict the American scene, the effect was somewhat thin and skeleton-like, worlds removed from the actual.

Meanwhile fresh movements in fiction were getting under way—movements that belong rather to the new century. At the age of 20 Stephen Crane (1871-1900) wrote *Maggie: A Girl of the Streets*, a brilliant sketch of slum life, and soon afterwards *The Red Badge of Courage*, a forerunner of later impressionistic work. In the middle '90s Frank Norris (1870-1902), under the influence of Zola, wrote two searching studies of character degeneration, *McTeague* and *Vandover and the Brute*, before turning to sociological fiction in *The Octopus* (1901). During these years the more classical forms of literature still lingered in the familiar fields. In poetry Madison Cawein (1865-1914) continued the Victorian nature tradition, and Richard Hovey (1864-1900) poured out vigorous Swinburnian verse. In drama Clyde Fitch (1865-1909) produced a number of clever society plays, and in the essay Agnes Repplier (1858-), more French than American in spirit, created a distinguished form of criticism. On the whole American literature was waiting for the coming of new forces to free it from dependence on Old-World models and make it native and adequate.

THE TWENTIETH CENTURY

A survey of American literature from 1900 to 1928 must deal chiefly with movements and tendencies rather than with masterpieces, schools and types. There are two reasons for this. We are still too close to our contemporaries to discriminate with even that reasonable probability of rightness which may be expected where time and taste have sifted the long-lived from the short. But an even stronger deterrent to dogmatic judgments is the nature of the period itself. In economical structure, in education, in social evolution, in politics, as well as in literature and the arts, the last three decades have abounded with change, in the United States even more than in other parts of the world. They witnessed the break-up of American self-sufficiency after the Spanish-American War; they saw the transformation of a country mainly agricultural into one predominantly industrial; they developed in their course a new capitalistic democracy, and a revival of nationalistic spirit, and they conclude with a sophistication of urban life different from any earlier culture in the history of the United States. In short, these three decades have been years of rapid transition toward a new social, moral, intellectual and economic order. But they are more than transitional. We have definitely entered upon a new epoch. An outline of American literature in this period must therefore be first of all a sketch of change and transition.

It is clear that the '90s of the last century in America as in England were not the beginnings, as was fondly supposed, of a new literary period, but rather the final efflorescence of an old trunk. The brilliant, mannered writing of the short story, the new-art magazines, such as *The Chap-Book*, the widespread imitation of the romantic elegance of Robert Louis Stevenson and the romantic virility of Rudyard Kipling, were of little significance for the immediate future of American literature. Only Jack London, with his stories of primitive, instinctive characters pursuing violent lives, expresses ideals of strenuousness with less subtlety than Kipling but with vigour in books like *The Call of the Wild* (1903) and *The Sea Wolf* (1904).

The late '90s and early 1900s were years of almost feverish writing. The American short story had reached a high pitch of technical skill and was finding a ready market in the new magazines which, like *McClure's*, were spreading to new classes of readers. The cult of local colour was being exploited for popular interest in narratives rich in dialect and local custom, but, if romantic, overcharged with sentiment, and, if realistic, specializing, like the stories of Mary Wilkins Freeman, in regional peculiarities. Satire was beginning in journalism with Peter Finley Dunne's dialogues of Mr. Dooley and the fables of George Ade, but was absent from formal literature and the stage. Poetry was limited to the ambitious, but rather academic, work of scholars like William Vaughan Moody, or to "magazine verse"—highly finished but conventional lyrics, brief and usually empty. Only one form of literary endeavour reached the magnitude of a school—historical romance.

The vast circulation, the great praise, the supposed significance of the historical romance in the America of the '90s and early 1900s are proofs that we are dealing with the end, not the beginning, of a period. Winston Churchill's *Richard Carvel*, Booth Tarkington's *Monsieur Beaucaire*, Paul Leicester Ford's *Janice Meredith*—these names echo but faintly now. They were stories in the direct tradition of Scott, Bulwer-Lytton, Dumas and the contemporary Stevenson. They were literary, with that slightly archaic style which is so offensive when its date is out; they were imbued with a thin romantic idealism, and while the hero made his own way in American fashion, there was little else American, or indeed contemporary, about them, except the frequent use of romantic scenes from early American history, which was a sign of the nationalism that accompanied the successes of the Spanish-American War. This vast literature of "best sellers" was read by most of the educated population of the country. It was the feeble conclusion of the great romantic movement of the 19th century.

There were forerunners of change before the end of the first decade. The vigorous cycle of Frank Norris, *The Octopus* (1901),

The Pit (1903), which dealt especially with the struggles between the producers and the new power of concentrated money, had wheat as its main theme, and these books, in spite of a tincture of romantic melodrama, were contemporary literature in a sense that the historical romance was not. Theodore Dreiser also had begun with *Sister Carrie* (1900) the attack upon American reticence which was later to result in the freeing of sex as a permissible dominant theme in literature. But his books, in spite of their subjects drawn from an unromantic democracy, were infected with a romantic megalomania, so that his would-be epics, *The Financier* (1912) and *The Titan* (1917) were akin in spirit, if not in mood, to the more elegant, but scarcely less unreal romances of colonial life which had been loved by the populace. The influence of his more realistic books, such as *Jennie Gerhardt* (1911), was thrown powerfully upon the side of naturalism in fiction. Stephen Crane, another experimenter in realism, was more noticed for the vividness with which his trenchant style endowed themes that had been merely romantic before than for the honest realism of his mood. His *Red Badge of Courage* (1895) was a *tour de force* that dates with the early brilliant stories of Kipling, and survives as a masterpiece of achievement in anti-romance rather than as a turning point in American literature.

Indeed, the causes for the great change in literary taste, which began in America about 1910 and was established by 1912, must be sought outside American literature. Among the intellectuals, where it began, it was due to a wide and earnest reading of the great anti-romantics of Europe—Bernard Shaw, whose attack upon the conventions of 19th century manners and morals and thinking made iconoclasm fashionable; the Russian novelists (fittingly introduced to American readers by William Dean Howells, last survivor of the first realistic period), who gave examples of a powerful fiction treating of people, like ourselves, unheroic, unpicturesque; and Ibsen, whose iconoclasm preceded Shaw's and was far more dogmatic. It was Europe that gave the literary stimulus to the new literature of 20th century America; but the stimulus was not simply literary.

In the first decade of the 20th century, the term "social conscience" first came into general use. A rapid increase in concentrated wealth, the creation of trusts, the closing of the American frontier, began to put an economic pressure that was not temporary upon the American, and brought him into a closer economic sympathy with Europe. Money as a power, the workers as a class, democracy as an economic factor, entered into the American consciousness. Roosevelt and Bryan made these ideas articulate; Upton Sinclair in his story of the meat industry, *The Jungle* (1906), gave concrete evidence; later the new English writers, H. G. Wells and John Galsworthy, especially, who dealt with the modern world as a complex in which the fate of men and women was determined by their environment, began to be widely read. Socialism, which had been dismissed in American universities of the '90s as played out, began to be discussed actively and a sturdy individualist, like William Graham Sumner, found that he had lived beyond his time and was unheard.

The immediate effect of all this social unrest was literary unrest. Romanticism seemed out of date. The new interest in classes created a new interest in individuals from those classes. The ordinary man in a commonplace environment entered American literature, not as a minor, but as a major character.

All this was intensified by the scientific education which since the last decades of the 19th century had been permeating all American schools and colleges. Experimental science, upon which the industrial advance of the period was based, produced in literature a realist attitude and a willingness to seek interest in the humble, the mean and the vicious. This partial realization of the scientific attitude through general education was the great factor in the change of literary taste.

TRANSITION

Poetry.—The change in literary values was, in America, sharpest in poetry. The so-called renaissance in American poetry might better be called a revolution. It was a result of new interests, new ideas acting upon the sensitive minds of the poets, and

resulting both in a new technique and in a clamorous insistence that poetry should once again become a literature of importance.

The makers of the new poetry in no real sense constituted a school. They included such diverse personalities as Ezra Pound with his cult of intellectualism; Amy Lowell who drew her first inspiration from France and was as much concerned with criticism as with creation (*Sword Blades and Poppy Seeds*, 1915; *Legends*, 1921); Edgar Lee Masters, a mid-Western lawyer, self-made in style and careless in choice of theme, whose *Spoon River Anthology* (1915) depended upon a bitter realism for its success; Robert Frost, a sensitive humorist who planed down the conventions of poetical rhetoric to the levels of unromantic New England (*North of Boston*, 1914; *New Hampshire*, 1923); also Edwin Arlington Robinson, who at first poured his shrewd observation of American character into racy, difficult verse, obscure, philosophic and pungent (*The Man Against the Sky*, 1916; *Tristram*, 1927); and Vachel Lindsay, a balladist and chanter of the Mississippi valley, who took up the native themes of the most American America—the frontier, the negro, revivalism (*General Booth Enters Heaven*, 1913; *The Congo*, 1914).

Two bonds only united these adventurers, around whom many others were soon grouped—an intense desire to make poetry once again vital in its expression, and a willingness to extend its province to include every new theme, however unlovely, which stirred the emotional mood. With Amy Lowell were ranked the advocates of free verse; with Masters those poets who, like Carl Sandburg (*Chicago Poems*, 1916; *Cornhuskers*, 1918; *Smoke and Steel*, 1923), found democracy and all its works, including industrialism, more truly poetical than the old themes. With Frost were less rebellious writers who, like William Rose Benét (*Merchants from Cathay*, 1913), Edna St. Vincent Millay (*Renaissance*, 1912; *A Few Figs from Thistles*, 1920), Louis Untermeyer (*Challenge*, 1914), sought to put the American mood as they felt it into poetry that was original not so much in form as in its impress of a living spirit.

But in all these poets, when at their best, realistic spirit (although by no means always realism), a willingness to experiment and a passionate interest in the new developing America were evident. Poetical criticism awoke with them and grew vociferous. Long poems appeared again, and new publications which, like Harriet Munro's *Poetry* (1912), were given entirely to verse. Poetry societies were formed and poetry began again to be heard as well as read. Cultivated Americans added poetry to their reading lists, but their rhythmic sense was blunted by disuse or stiffened by convention, and it was the novelty, not raucousness of free verse which called forth criticism, a fact responsible in part for the subsidence of the most promising movement in American poetry since the New Englanders of the 19th century.

Fiction.—The full effect of the transformations of the early 19th century did not show itself until after the World War. Just before this period Henry James had been writing the last and most complex of his novels (*The Golden Bowl*, 1904), and while he was to be reckoned as more cosmopolitan than American, his example was indicative of what was to happen in America. The American novel had a good tradition behind it, and in every period there were sound examples where imagination and the reality which must always accompany a novel were happily blended. The chief effect of the awakening of a new artistic consciousness in America and the breaking of the shackles of convention was to be seen in the fine series of novels of contemporary life in which Booth Tarkington (converted from pure romance), Edith Wharton, Joseph Hergesheimer and Willa Cather were beginning a more thorough-going study of the American scene than had been attempted before. This includes Booth Tarkington's *Penrod* (1914), which though a collection of short stories has continuity, *The Magnificent Ambersons* (1918), *Alice Adams* (1921) and *The Philocrat* (1927); Edith Wharton's *The House of Mirth* (1905), *The Custom of the Country* (1913) and *The Age of Innocence* (1920); Willa Cather's *O Pioneers!* (1913), *The Song of the Lark* (1915), *My Antonia* (1918), *A Lost Lady* (1923) and *Death Comes for the Archbishop* (1927); Joseph Hergesheimer's *The Three Black Pennys* (1917) and *Java Head* (1919).

These novels (if we include Henry James's) are more competent in their craftsmanship than any of the past half century with the exception of the best of Howells, and are richer emotionally than his. Their kind was to grow in power and variety for another two decades, and in them is to be seen the fruition of that careful workmanship and loving interest in the character types of American civilization which had been bred in the local-colour short stories of the generation before.

The short story was differently affected by the new currents of American life. It had begun as a filler for the magazines, had risen quickly into literature, and now began to descend toward journalism again. The standardizing of American life was accompanied and accelerated by the vast growth in circulation of the magazine, and a resultant demand for short fiction. To this the short story responded in two ways. First, the craftsmanship which could make an interesting story out of 3,000 words was stereotyped, and soon began to be taught in college courses, so that anyone with a tale to tell could learn to put it in acceptable form. A flood of good stories flowed over the land, which, when reprinted in book form, proved to be not so good. Only occasional masterpieces, like Edith Wharton's *Ethan Frome* (1911), which is really a belated phenomenon of the '90s, stand out from the mass. Secondly, the most successful new writers wrote in strict conformity with the needs of journalism. O. Henry (William Sydney Porter), in *The Four Million* (1906), borrowed the method which Aldrich and Bunner had used in the 19th century, and made stories of a popularity only to be compared with the romantic best sellers that preceded him. His influence was great upon short-story journalism, but has small relation to the changes in American life which were reflected in the contemporary novel.

Parallel Developments.—The swing from romance toward a harder intellectualism and a more realist study of contemporary life as it was manifested in this transition literature was, indeed, a phase of the general change in the American mind. In journalism the democratizing and vulgarizing of the newspaper, which had begun some years before, was an effect of better economic conditions for the classes that had hitherto not read at all, and influenced literature only by breeding innumerable writers alert to catch and follow the taste of the broadest American public. But new intellectual tendencies were evident even in the newspapers. The humorous column now began, with B.L.T. (Bert Leston Taylor) of the *Chicago Tribune* and Franklin P. Adams and Don Marquis of New York, to take that edge of harder satire which was to characterize the new age. At about the same time, the illustrated literary magazine, which had been America's chief contribution to periodical literature, began to lose its vitality and give way to the new weeklies for men and women, like *The Saturday Evening Post* and *The Ladies Home Journal*, which, with more journalism and less literature, became the staple reading of the American bourgeoisie. Beside the older magazines came into existence new vehicles of thought, some of them, like *The New Republic*, created to express the intellectual unrest of an American generation quickly outgrowing provincialism, others, like the revived *Nation*, organs of new social ideas, still others, like *The Yale Review*, expressive of a new spirit in the American universities, which were now ready to leave their specialization and take part in a reconstruction of American thinking. On the stage the change was even more marked, but as yet American talent took only a minor part, though it was in these transitional years that New York began to rival London and Paris as a market for dramatic ideas.

The Essay and Criticism.—The essay, in which American literature, with Emerson and Thoreau, had shown great originality, was in the hands of conservatives. The graceful humour of Samuel McChord Crothers (*Humanly Speaking*, 1912), the caustic criticism of Agnes Repplier (*Counter Currents*, 1916), were such as might emanate from highly civilized writers in any age. In criticism there was little revival until after the war, although from this period date the first efforts to supply new grounds for judgment of contemporary writers, the work of Van Wyck Brooks (*America's Coming of Age*, 1915), Joel Elias Spingarn (*The New Criticism*, 1911) and Randolph Bourne (*Youth and Life*, 1913).

Academic criticism was still concerned almost exclusively with literary history, and was notably uncritical of anything but facts. It ignored American literature, which, from the time of Poe and the great New Englanders until the post-war period, went without serious scrutiny. A few accomplished scholars of humanistic trend, such as W. C. Brownell (*American Prose Masters*, 1909) and Paul Elmer More (*Shelburne Essays*, 1904-), made distinguished contributions in traditional fields, but there was little vitality in the criticism of contemporary literature. Note should be made of the brilliant criticism of life, half literary, half philosophical, of George Santayana (*Winds of Doctrine*, 1913, *Character and Opinions in the United States*, 1920.)

A vigorous exception was James Huneker, whose highly coloured observations on native and foreign writing in the New York newspapers had the virility and immediate interest which general criticism lacked (*Promenades of an Impressionist*, 1910; *Ivory, Apes and Peacocks*, 1915).

WAR AND POST-WAR

The World War had a dominant effect upon American ideas, but much less upon American imagination. In the first three years of the conflict, when the United States was a noncombatant, a flood of European writing was discharged upon the country, and this was met by an equal outpouring of American writing upon European topics. Europe was analysed, explained, inspected, as never before in American history. Some of this writing was mere propaganda, but much of it, whatever its purpose, was a sincere attempt to understand the French, the British and the German mind. It is difficult to over-estimate the effect of this cosmopolitan reading upon the American public. The interest in foreign literatures, already spreading rapidly in the transition period, was strengthened. Authors who had been national, like Rolland or Ibañez, became international.

The period of the war itself saw no more than a steady development of the tendencies already mentioned, although the change in American perspective put an end to the lingering reputations of the old romantic school. Kipling and Stevenson disappeared as foreign influences. The atmosphere of war discussion was unfavourable to poetic themes, whether realistic or idealistic.

But the years immediately succeeding the war brought new developments, whose importance is only now becoming evident. There was, as after most wars, a sharp revival of nationalism. This nationalism, however, was of a special character, in that it reflected the inevitable contrast and comparison which resulted from a vast migration of Americans abroad and an almost equally great inroad of European ideas at home.

The new nationalism took several forms. In the remarkable series of works by Sinclair Lewis, *Main Street* (1920), *Babbitt* (1922), *Arrowsmith* (1925), *Elmer Gantry* (1927), the provincial self-satisfaction of the prosperous, half-educated American, his decayed idealism, his aimless strenuousness, his perfunctory morality were more bitterly attacked than was deserved. Implied contrast with the proper attributes of a citizen of the world was the characteristic basis of these novels, in which respect they closely resemble the parallel work of H. G. Wells. Lewis's *Babbitt* is perhaps the most important work in fiction of the whole period.

The scene of Lewis's novels is prevailingly the Middle West, and it is the emergence of the Mississippi valley (and later of the Old South) as a social *milieu* stimulative of serious fiction that is a second characteristic of this post-war nationalism. The distinguishing feature in the novels, whether historical, like Herbert Quick's *Vandermark's Folly* (1922), or psychological, like Elizabeth Roberts' *Time of Man* (1926), or expressionistic, like Glenway Wescott's *The Grandmothers* (1927), or objective, like O. A. Rölvaa's *Giants in the Earth* (1927) is the self-consciousness of the authors as regards this middle America. They feel that it is the real America, as the New Englanders before them had felt of New England, and their novels of farm life are intended to be, and are, studies in typical American problems.

A third aspect of the contemporary nationalism is the increased interest in the American past. American history as a study for the general reader revived after a long eclipse with such books as

were included in the "Chronicles of America" series. But in the decade since the war this interest has been greatly extended and has resulted in a rewriting of the biographies of most of America's famous men, and many fresh contributions to the truth about the American past. The social history of America is now being written for the first time by such scholars as Allan Nevins, James Truslow Adams, Lewis Mumford, Charles Beard and Vernon Louis Parrington. (See particularly *Main Currents in American Thought* [1927], by Parrington; *The Golden Day* [1926], by Mumford; *The Rise of American Civilization* by Charles and Mary Beard.) Many important studies of America's past, like the *Education of Henry Adams* (1918) by the historian of that name, *A Son of the Middle Border* (1917) by Hamlin Garland, and *The Mauve Decade* (1926) by Thomas Beer, are so close to the field of psychological fiction as to be almost indistinguishable from it.

Naturalism.—Yet the chief change in American literature since the war has had little to do with either the war or nationalism. It is a logical development of the revolt against Victorian conventions which began before 1910 and was international in its scope. One manifestation is the escape of sex. It is a mistake to suppose, as the first critics of the tendency thought, that sex was suppressed in 19th century literature. It was inhibited, but not so much by convention as by a lack of interest in its problems. The scientific training of several generations has had much to do with this change in attitude, but there is also the determination of the realists to get at new truths in human relationships, and the stimulus to all such desires resulting from the disillusion of war. Sex is not the dominant theme of important American literature in this period, but it is far more important and far more freely handled than ever before. The success of such books as Gertrude Atherton's *Black Oxen* (1923), Dreiser's *American Tragedy* (1925), Sherwood Anderson's *Winesburg, Ohio* (1919), Scott Fitzgerald's *This Side of Paradise*, must be set down in part to their treatment of sex problems.

A truer conception of the change, however, is attained if such books are regarded as an offshoot of the interest which has created the new psychology in which American scientists have taken a prominent part. The problem has been to throw off all conventions and inhibitions so as to uncover the springs of the human machine. This, of course, is a substitute for the earlier desire to find the nobler motives of mankind, and is by no means necessarily an artistic advance. Yet the frank realism, and the minute study of normal, subnormal and abnormal phenomena which has resulted, have given rise to the halting but deeply moving sketches of Sherwood Anderson as surely as to the achievements of science. Inevitably this literature is thoroughly American for it is a study of actual Americans, whether apparently ordinary, as in the books just named, or extraordinary, as in the sonnet sequence, *Two Lives* (1925), of William Ellery Leonard. In the drama the same impulse has blended with an imaginative phantasy that gives it less conviction perhaps but more beauty, as in the impressive series of plays by Eugene O'Neill, particularly *The Emperor Jones* (1921), *Anna Christie* (1922) and *Strange Interlude* (1928).

These interests are responsible for the appearance in American fiction of what the French in Zola's day called naturalism. The farm novels of the Middle West are prevailingly naturalistic in method. The desire to make a complete social, psychological and physical document is predominant in Theodore Dreiser. It is visible in such different writers as the story-tellers Fannie Hurst and Edna Ferber, in the carefully wrought backgrounds of Joseph Hergesheimer and in the studies of human appearance in Sherwood Anderson. It is visible also in the meticulous backgrounds of the sentimental and standardized cinema pictures of the time.

A last major phenomenon is the sophistication of America and particularly of the literature coming from New York and Chicago. This is a natural concomitant of America's share in world wealth and world leadership, and of its recent hospitality to foreign ideas. Sophistication is a rhetorical rather than a literary term, but in this instance it is used to describe a taste for wit, for pointed satire, for cynicism, for the subtleties of social contact when given the ease and lightness of literary form.

On the stage it has led to fantastic satires and the admirable setting of the otherwise banal musical comedy; in the novel it is responsible for the witty brilliance of Thornton Wilder (*The Bridge of San Luis Rey*, 1927), the philosophic dialogues of John Erskine, the most noteworthy of which was *The Private Life of Helen of Troy* (1925), and the exquisite artificiality of Elinor Wylie's *Jennifer Lorn* (1923); in poetry it can be seen in the intellectualism of Amy Lowell and T. S. Eliot (*The Wasteland*, 1922), although other stronger influences enter here, and in the sharp-cut lyrics by Elinor Wylie (*Black Armor*, 1923); in the essay in the trenchant iconoclasm of H. L. Mencken, an ardent conservative appealing to realists weary of naïveté, progress and sentiment through his *Prejudices* (1919 seq.) and his organ, *The American Mercury*.

Most striking of all is the welcome which a sophisticated America has given to experimental literature, as Christopher Morley's *Thunder on the Left* (1925) or John dos Passos' *Manhattan Transfer* (1925). Even such poetry of experimental technique as Edward Estlin Cummings' *Tulips and Chimneys* (1923) and such plays as John Howard Lawson's *Processional* (1925) have been widely discussed.

These new currents in literature, and particularly the increasing interest in everyday life as a theme and in new forms of literary expression, have naturally brought with them a new vigour of criticism, signalized by the appearance of a new generation of critics who, like Van Wyck Brooks, apply scientific theories to American literature, or like H. L. Mencken, clear away the rubbish of old conventions for the benefit of a new realist middle class, or like Stuart P. Sherman, come out from the universities to apply their knowledge of the continuous stream of literature to the interpretation of new things. The founding of the new *Dial* in 1920, of *The Literary Review* of *The New York Evening Post* in 1920, afterwards carried on as *The Saturday Review of Literature* from 1924, and the appearance in 1925 of *Books*, the literary supplement of *The New York Tribune*, are indicative of the new interest in critical opinion.

Various literary manifestations of the period do not readily fit into the categories and tendencies described above, although doubtless in 20 years they will easily indicate their relationship.

The work of James Branch Cabell, beginning as pure romance, and becoming with *Jurgen* (1919) and its successors more and more ironical, philosophic and symbolic, is an instance. In general, Cabell clearly belongs to the generation of the 1910s that wearied of moral conventions sugared over with sentiment and attacked the *mores* of the 19th century. His almost fantastic playing with eroticism is in part at least mere rebellion against the censorship that had been imposed upon 19th century popular literature. But his elaborate mediaevalism is quite as clearly a survival from the period of romance, and his elaborate literary backgrounds represent a devotion to style for its own sake quite distinct from the tendencies of the time, and not to be confused with the sophisticated elegance of the young writers of the late 1920s. His cult is due in part to his sometimes witty eroticism, in part to his position as an authentic man of letters in a journalistic era, who writes only for the instructed. He is perhaps best understood as a survival from the '90s. Interesting comparisons can be made between Cabell and those earlier philosopher-phantasists of America, Hawthorne, Melville and Poe.

The Short Story.—It is not so difficult to relate the course of the short story, America's own invention, in the third decade of the century. While individuals, like Ruth Suckow (*Iowa Interiors*, 1926), Sherwood Anderson (*The Triumph of the Egg*, 1921), Ernest Hemingway (*Men Without Women*, 1927) and Ring Lardner (*How to Write Short Stories*, 1924) (who, like so many American humorists is fundamentally a satirist) wrote short stories that broke away from the technical convention of suspense and climax, the main stream of American short stories increased in volume without contributing much to the knowledge of American life or anything new to the art of fiction. Indeed the best writers, like Wilbur Daniel Steele (*The Man Who Saw Through Heaven*, 1927), were clearly hampered by a technique of quick and vivid telling that made their most authentic work seem artificial. Even the

careless reading public began to rebel against these pyrotechnics, and the vogue of "confessions" in magazines that purported to give true stories may be assigned as much to a distaste for the obviously worked-up story as to an innate love of scandal.

The worldwide success of the American cinema picture is a literary phenomenon, even though the scenarios are seldom literature. In substance, the stories belong almost exclusively to the type made popular 30 years earlier in the heroic romance, or to even more primitive forms of realistic melodrama. This is merely to say that the millions are a generation at least behind the thousands in their literary tastes, and crave certain fundamental emotional reactions without reference to time or taste. In other respects, however, cinema pictures are strictly contemporary. Like the short story, they have developed a technique so skilful and so stereotyped that there is no escape for a story once it enters the machine. Like the modern automobile, they represent great efficiency of appeal at small cost to the intellect, gained by careful standardization of emotional reactions.

Finally, the reading habits of the American public were in this period definitely altered. They read more magazines and more magazine material in their newspapers. The wide public of semi-literate readers became more critical of their fare, and while it cannot be said that they demanded better substance, they did require a more competent form. The general level of American writing, whether in books, periodicals or the press, was decidedly raised. "Fine writing," diffuseness, mere rhetoric, crudity of expression, became rarer in publications of general circulation. Only vulgarity increased.

As for the more literate public who read books, their tastes and interests notably broadened. They were capable of buying nearly 200,000 copies of Will Durant's *Story of Philosophy* (1926), which was really a story of philosophers. They read more and more foreign books in translation, were intensely interested in problems of psychology and social development raised by such books as James Harvey Robinson's *The Mind in the Making* (1921), demanded biography, in which they liked the new satirical note, and in general proved that the craving for self-education, always strong in America, was manifesting itself more widely than ever before. Magazines like *The American Mercury* and the reinvigorated *Harper's* of 1925 were devoted to this new intellectualization of the American reader. Publishers' lists were notably broader, and sales of non-fiction books increased.

Conclusion.—It is clear that the history of American literature in the period 1900–28 is meaningless without reference to the great social and intellectual changes which went on in the America of those decades. It is not an "age" in the literary sense, in which a group of characteristic works can be selected to represent a characteristic genius. Rather, the most interesting, though not necessarily the most permanent, books, are those which most illustrate revolt, change and discovery. If it is to be named at all it must be called an age of fiction, for the quick response to social and intellectual change is best represented in the fiction of the epoch.

From another point of view it was a period of anti-idealism in literature. The efforts of critics like H. L. Mencken, the tone of the realistic and satiric novel and play, the course of historical and scientific writing, even the poetry of the epoch, were all as predominantly set toward a realist's view of the universe as 19th century American literature was turned toward idealism.

In any case it is probable that the two latter decades of the period represent the real beginning of America's coming of age in arts and letters. Like the New England renaissance of the 1840s, they follow upon a period of rapid economic progress, and although the industrial reorganization of the United States has probably postponed the period of complete literary expression, we may expect some interesting sequels to the vitality now manifested in every department of American literature except poetry.

(H. S. C.)

AMERICAN LOCOMOTIVE COMPANY, a large manufacturer in the United States of locomotives and locomotive accessories. Its output in 1928 included steam, electric and oil locomotives, and also springs, tires and wheels for locomotives and railway cars. Upon its incorporation in 1901, the company acquired the plants and business of eight important manufacturing concerns, all of which had been in operation for many years, seven having been organized prior to 1870, including the Schenectady Locomotive Works dating from 1848. In 1904 the American Locomotive Company acquired the Locomotive and Machine Company of Montreal, Ltd., now the Montreal Locomotive Works, Ltd.; in 1905 it acquired the Rogers Locomotive Works of Paterson, N.J. (organized in 1831); and in 1917, the Chester, Pa., Foundry of the Penn Seaboard Castings Company. It also owns the American Locomotive Sales Corporation which holds membership in the Locomotive Export Association formed to manage the foreign business of both the American Locomotive and the Baldwin Locomotive Works. In 1926 the company acquired the Railway Steel-Spring Company, incorporated in New Jersey, then the largest manufacturer of railway springs and tires in the United States.

Following its policy of concentrating the manufacture of locomotives at its largest and most modern plants, the company has sold a number of its smaller establishments. In 1928 the plants operated were locomotive works at Schenectady, N.Y., Dunkirk, N.Y., Richmond, Va., and Montreal, Canada; there were in addition a steel foundry at Chester, Pa.; a locomotive accessories plant at Richmond, Va.; and spring, tire and wheel plants at Latrobe, Pa., Chicago Heights, Ill., East St. Louis, Ill., and Montreal, Canada. The company has introduced and sponsored in America many standard features of steam locomotives, including the fire-tube superheater, and has developed the Mallet locomotive and the three-cylinder locomotive for American use. During the earlier years of the World War the company devoted nearly the full capacity of its plants to the manufacture of munitions for the British and Canadian Governments, but at the beginning of 1918 restored its plants to the building of locomotives for the use of the American forces in France and for the railways of the United States. When incorporated in 1901 the company had a capital stock of \$50,000,000, consisting of 250,000 shares of 7% cumulative preferred stock and 250,000 shares of common stock. In 1926 the capital stock had been increased to 385,000 shares of 7% cumulative preferred stock (with par value \$100), and 770,000 shares of common stock without par value. At the close of 1927 the company possessed property, less depreciation reserves, amounting to \$58,500,000; current assets, \$50,500,000, including \$37,000,000 in cash and marketable securities; total assets, \$111,000,000; and surplus, \$28,000,000. The executive offices are in New York city. (W. H. W.)

AMERICAN MEDICAL ASSOCIATION, a federation of 54 constituent state and territorial medical associations. It was organized in 1847, and had 94,000 members in 1928. The objects of the association are to promote the science and art of medicine and the betterment of public health. It is divided into the following departments: editorial, council on scientific assembly, council on medical education and hospitals, council on pharmacy and chemistry, judicial council, council on physical therapy, bureau of health and public instruction, bureau of legal medicine and legislation, bureau of investigation, clinical laboratory and library. The association publishes the *Journal of the American Medical Association* (weekly), Spanish edition of the *Journal of the American Medical Association* (semi-monthly), *Archives of Internal Medicine*, *American Journal of Diseases of Children*, *Archives of Neurology and Psychiatry*, *Archives of Dermatology and Syphilology*, *Archives of Surgery*, *Archives of Otolaryngology*, *Archives of Pathology and Laboratory Medicine*, *Quarterly Cumulative Index Medicus*, and *Hygeia*, *The Health Magazine* (for the general public). The headquarters are at Chicago, Illinois.

AMERICAN NEWSPAPER PUBLISHERS' ASSOCIATION, an organization of newspaper publishers of the United States and Canada. It comprises about 500 of the leading newspapers. The purpose of the organization is to standardize and stabilize the newspaper publishing business. Its activities are divided into three different divisions: (a) traffic; (b) labour; and (c) mechanical. (a) The traffic department deals with matters connected with the handling of freight. It employs an expert in transport who checks freight charges for the various members and assists in securing rebates where over-charges have been made. He also acts as a representative of the members in securing satisfactory service and proper adjustment of rates from various carriers. (b) The labour department acts as the official representative with the labour unions in making contracts and adjusting differences. It also operates what is called the open shop department which may be called upon for help in acute labour troubles but the association claims that this "is by no means a strike-breaking organization." (c) The mechanical department acts in an advisory capacity for the mechanical problems that arise in printing.

The association also maintains a collection department and an information department. These are for the exclusive service of members. In addition to these, there are a considerable number of miscellaneous activities such as those of the postal committee which represents the association in matters dealing with the postal authorities concerning rates and regulations. There is also a committee which extends aid and encouragement to printing trade schools. The association holds an annual convention at which the various publishers meet to discuss topics of mutual interest.

(H. E. A.)

AMERICAN PSYCHOLOGICAL ASSOCIATION, INCORPORATED, THE, was founded on July 8, 1892, at a meeting held at Clark university, Worcester, Mass., attended by G. Stanley Hall, George S. Fullerton, Joseph Jastrow, William James, George T. Ladd, James McK. Cattell and J. Mark Baldwin as the original members. The first meeting was held at Philadelphia in December of the same year, under the presidency of G. Stanley Hall, at which time 24 more members were elected. The object, as stated in the original constitution, was "to advance psychology as a science," and the association has never deviated from this guiding principle. Since the founding, annual meetings for the presentation of scientific papers have been held at the different psychological laboratories in December of every year. The association was incorporated in the District of Columbia in 1925. Throughout its history the standard of membership has been maintained at a high level. To be admitted to membership, the degree of doctor of philosophy in psychology is necessary together with publication of an important contribution in the scientific journals. In 1924 the association introduced the grade of associate membership.

The association publishes annually a year book and proceedings of the annual meeting and owns and publishes six psychological journals. The association in 1928 had 534 members and 165 associate members.

AMERICAN RADIATOR COMPANY, THE, an Illinois corporation, was formed in 1892 by the union of the Pierce Steam Heating company, Michigan Radiator and Iron company and Detroit Radiator company, with headquarters in Chicago, Ill.

At its inception the company manufactured radiators only, but a few years later engaged also in manufacture of cast iron boilers. The radiators manufactured by the company were of the cast iron sectional type, the use of which had not yet become general. Much of the early success of the company was due to the dominance attained by this type of radiator. Another of the major policies which contributed largely to its success was that of selling only to heating plants. Prior to that time manufacturers had retarded the development of the heating profession by making plans, supervising installations and maintaining sole agencies. The founders of the company visualized that the development of heating as a science was essential if the scope of radiator heat was to extend beyond the larger buildings.

In 1899 there was organized the present company, a New Jer-

sey corporation of the same name, as successor to the Illinois corporation, and four other concerns in the industry joined in the new merger. From its inception the growth and progress of the company has been continuous. Much of its success in the popularization of radiator heat has been due to technical and manufacturing experimentation and the development of new products which have resulted in a large production and popular prices. Radiator heat, once a luxury, is now the standard of heating comfort and is available at a cost not out of proportion for moderate sized residences and buildings of all types. In 1928 the company was operating 62 branches and sales offices, with warehouses in all of the larger centres. It operates 30 plants in the United States and Canada in the manufacture of boilers, radiators, hot water heaters and various heating accessories; the company also owns and operates coal mines, coke ovens and pig iron furnaces. In Europe 11 manufacturing plants are engaged in the manufacture of like products, with sales offices and showrooms in the leading cities. (C. M. Wo.)

AMERICAN RAILS, a term used on the London Stock Exchange to describe the stock and bonds of the United States railways, which are dealt in by a distinct market. The shares and bonds of American railroads are issued in a way which almost constitutes them bearer securities, for they bear a transfer form on their backs. (See STOCK EXCHANGE.)

AMERICAN RAILWAY EXPRESS, THE, was incorporated in 1918 to engage in the general transportation business. The company immediately took over from the American, Adams, Southern and Wells Fargo express companies all their properties used in domestic express transportation. From July 1, 1918, the American Railway Express has carried on the domestic express business of these concerns, which retained, however, their properties and business not connected with the express activities. In 1920 it bought the real property and the equipment used in the express business of the Western, the Northern and the Great Northern express companies. Since Sept. 1, 1920, the company has operated as a common carrier under the jurisdiction of the interstate railway commission. It carries all the railway express business of the United States except that of the Southern railway system and a few minor roads. It functions also through steamship lines, electric railways and ferries, its business extending to Canada and the possessions of the United States. Air service was begun on Sept. 1, 1927, through contracts with air-transport companies. The first air-express routes were between Chicago and four other cities—New York, Dallas, San Francisco and Los Angeles.

At the end of 1926 the total mileage operated by the American Railway Express in the United States and adjacent countries was 249,863, classified as follows: steam railways, 221,979; coast-wise steamship lines, 11,539; transoceanic steamship lines, 6,620; inland steamship lines, 6,250; electric railways, 2,890; stage routes, 574; ferries, 11. The company maintains 25,597 offices—22,107 of these with the railways—and has approximately 90,000 employees, including those employed jointly with the roads. In 1926 the company paid to carriers for express privileges alone, \$147,812,159. In that year there was an outstanding capitalization of \$34,642,000, and the ownership of the company was vested as follows: American Express Company, \$13,062,400; Adams Express Company, \$10,914,300; Southern Express Company, \$1,000,000; and the public, \$9,665,300. The company's current assets were \$34,463,909; total assets, \$72,380,644; net income, \$2,318,347. Its headquarters are in New York city. (R. E. M. Co.)

AMERICAN REVOLUTION, THE (1775-1781), known also as the American War of Independence. This war, by which the United States definitely separated themselves from the British connection, began with the affair of Lexington in Massachusetts, on April 19, 1775, and was virtually ended by the capitulation of Cornwallis at Yorktown, Va., on Oct. 19, 1781. In this article the progress of the war itself is alone considered, its political side being treated under UNITED STATES: *History*. From a military standpoint as well as politically it was a conspicuous and instructive conflict. It was conspicuous as being the most famous struggle in history where colonial dependencies defeated

their mighty parent state, though the powerful aid of France, Spain and Holland must never be forgotten. It was instructive as presenting exceptional conditions and consequent errors in the attempt to break down the revolt. The reasons for Great Britain's failure appear in the progress of the war, which assumed two distinct stages: operations in the north, followed by operations in the south. In point of time and energy military activity was

AFTER THE PAINTING, "THE DAWN OF LIBERTY," BY COURTESY OF THE LEXINGTON (MASS.) HISTORICAL SOCIETY

THE FIRST ARMED CONFLICT OF THE REVOLUTION. A SKIRMISH AT LEXINGTON ON APRIL 19, 1775, BETWEEN THE "MINUTEMEN" UNDER CAPTAIN JOHN PARKER AND BRITISH REGULARS UNDER MAJOR JOHN PITCAIRN

about equally divided between these two fields. As the naval operations in connection with the war have a European interest as well, they are dealt with in a separate section.

Land Operations.—To strike at the rebellion first in the north was natural and inevitable. To King George and his ministry, Massachusetts was the hotbed of disloyalty, the head and front of opposition to their colonial policy, and there coercion should begin. It was also a convenient point for a prompt display of authority, as the town of Boston was the headquarters of Gen. Gage, recently appointed royal governor of Massachusetts and commander of the king's troops in North America. He had with him four regiments of regulars, the initial force with which to overawe the restless and defiant population in his vicinity. While Gage is to be credited with advising his government that not less than 20,000 men would be necessary for the work in hand, he proceeded after some delay to suppress warlike preparations near Boston. His first determined effort brought about the skirmish of April 19, 1775 (see LEXINGTON), in which a detachment sent to seize some military stores collected at Concord suffered heavily at Lexington, Concord and other places, at the hands of the surrounding militia. This encounter roused the New England colonies, and in a few days some 16,000 of their townsmen marched in small bands upon Boston to protest against and resist further incursions; and in this irregular body we have the nucleus of the colonial forces which carried the war through. A noteworthy incident of the Lexington affair, and characteristic of the attitude which the provincials had maintained and continued to maintain for another year, was the official representation to the king that the regulars were the first to fire, and that the colonials returned the fire and fought through the day in strict defence of their rights and homes as Englishmen. Who actually fired the first shot, no man knows. They repeated their professions of loyalty to his majesty and the principles of the English constitution. Conscious, nevertheless, that a struggle impended, they instantly sent word to all the other colonies, whose whig elements sympathetically responded to the alarm. The war had opened.

The home government extended its precautions and preparations. General (Sir) William Howe, who succeeded Gage in the chief command in October, and Gens. (Sir) Henry Clinton and John Burgoyne were sent out at once with reinforcements. Cornwallis followed later. These four generals were identified with the conduct of the principal operations on the side of the British. The force at Boston was increased. The American Congress at Philadelphia, acting for the 13 colonies, voted general defensive

measures, called out troops and appointed George Washington of Virginia commander-in-chief. Before he reached the camp forming around Boston, a second and more important collision took place. On June 17, 1775, occurred the battle of Bunker Hill (*q.v.*), in which, although victorious, the British suffered heavily, losing one-third of their force in storming the hastily constructed lines of the "rebels." In moral effect the battle proved anything but a defeat to the Americans, who now drew a cordon of works around Boston, hemming Howe's army in a contracted, and, as it proved, untenable, position. On July 3, Washington took command of the American army at Cambridge and proceeded with what is known as the "siege of Boston," which was marked by no special incident, and closed with the American seizure of Dorchester Heights and the evacuation of the town by the British on March 17, 1776, Howe sailing away to Halifax, Nova Scotia. While the main interest centred at this point, the year 1775 was marked by two enterprises elsewhere. Fort Ticonderoga, the key to the passage of Lakes George and Champlain to Canada, was surprised and taken on May 10 by a small band under Col. Ethan Allen, while Col. Benedict Arnold headed an expedition through the Maine woods to effect the capture of Quebec, where Sir Guy Carleton commanded. Arnold joined Gen. Richard Montgomery, who was already near the city, and the combined force assaulted Quebec on Dec. 31, only to meet with complete defeat. Montgomery was killed and many of his men taken prisoners. Demonstrations against Canada were soon discontinued, Arnold drawing off the remnant of his army in May 1776.

The events of 1775, though partly favourable to America, were but a prelude to the real struggle to come. For the campaign of 1776 both sides made extensive preparations. To the home government the purely military problem, although assuming larger dimensions and more difficulties, still seemed to admit of a simple solution, namely, to strike hard where the rebellion was most active and capable of the longest resistance. Defeated there, it would quickly dissipate in all quarters. As much more than one-half of the population and resources of the colonists lay north of Chesapeake Bay—New England alone having an estimated population of over 700,000 persons—it was only a question as to what point in this area should be made the future base of operations. Largely upon the representations of Howe, Burgoyne and others, it was determined to shift the field from Boston to New York city, from there to hold the line of the Hudson river in co-operation with a force to move down from Canada under Carleton and Burgoyne, and thus effectually to isolate New England.

Upon this plan the new campaign opened in June, 1776. Howe, heavily reinforced from home, sailed on June 10 from Halifax

directed movements upon the American left. On Aug. 22 he crossed the Narrows to the Long Island shore with 15,000 troops, increasing the number to 20,000 on the 25th, and on the 27th surprised the Americans, driving them into their Brooklyn works and inflicting a loss of about 1,400 men. Among the prisoners were Gens. J. Sullivan and W. Alexander. (*See LONG ISLAND.*) Howe has been criticized, rightly or wrongly, for failing to make

THE LANDING OF THE BRITISH FORCES IN NEW JERSEY

After the capture of Ft. Washington in New York the British crossed the Hudson under the Palisades and pushed across New Jersey with designs on Philadelphia

full use of his victory. Washington skilfully evacuated his Brooklyn lines on the night of the 29th, and in a measure relieved the depression which the defeat had produced in his army. On Sept. 15, Howe crossed the East river above the city, captured 300 of the militia defending the lines and occupied the city. Washington had withdrawn his main army to the upper part of the island. A skirmish, fought the next day, opposite the west front of the present Columbia university, and known as the affair of Harlem Heights, cost the British a loss of 70 of their light infantry. Delaying until Oct. 12, Howe again moved forward by water into Westchester county, and marching toward White Plains forced another retreat on Washington. In the fight on Chatterton Hill at the Plains, on Oct. 28, an American brigade was defeated. Instead of pressing Washington further, Howe then returned to Manhattan Island, and, Nov. 16, captured Fort Washington with nearly 3,000 prisoners. This was the heaviest blow to the Americans throughout the war in the north. The British then pushed down through New Jersey with designs on Philadelphia. Washington, still retreating with a constantly diminishing force, suddenly turned upon Lieut.-Col. Rall's advanced corps of Hessians at Trenton on Dec. 26, and captured nearly 1,000 prisoners. This brilliant exploit was followed by another on Jan. 3, when Washington, again crossing the Delaware, outmarched Cornwallis at Trenton, and marching to his rear defeated three British regiments and three companies of light cavalry at Princeton, New Jersey. Marching on to Morristown, Washington encamped there on the flank of the British advance in New Jersey, thus ending the first campaign fought on the new issue of American Independence, which had been declared on July 4, 1776.

While these closing successes inspired the Americans, it was undeniable that the campaign had gone heavily against them. Having raised a permanent force for the war called the Continental Line, they awaited further operations of the enemy. Following up the occupation of New York, Howe proceeded in 1777 to capture Philadelphia. Complete success again crowned his movements. Taking his army by sea from New York to the head of the Chesapeake, he marched up into Pennsylvania, whither Washington had repaired to watch him, and on Sept. 26 entered the city. The Americans attempted to check the advance of the British at the river Brandywine, where an action occurred on the 11th resulting in their defeat (*see BRANDYWINE*); and on Oct. 4, Washington directed a well-planned attack upon the enemy's

AFTER A SKETCH BY AN ENGLISH OFFICER ABOARD ONE OF THE FLEET. BY COURTESY OF THE N.Y. PUBLIC LIBRARY
THE BRITISH FLEET UNDER ADMIRAL HOWE AT ANCHOR IN NEW YORK HARBOUR JUST AFTER THE BATTLE OF LONG ISLAND

to New York and on July 5 encamped on Staten Island. Washington, anticipating this move, had already marched from Boston and fortified the city. His left flank was thrown across the East river beyond the village of Brooklyn, while his front and right on the harbour and North or Hudson river were open to a combined naval and military attack. The position was untenable since the British absolutely dominated the waters about Manhattan. Howe drove Washington out of New York, and forced the abandonment of the whole of Manhattan Island by three well-

camp at Germantown on the outskirts of the city, but failed of success. (See GERMANTOWN.)

Howe's victorious progress in Pennsylvania was neutralized by disasters farther north. Indeed his whole expedition to seize "the enemy's capital" was nothing less than an abandonment of an expedition from the north with which he was expected to co-operate. Clinton, whom he left at New York, protested against

FROM "ANNALS OF PHILADELPHIA," 1830

BRITISH BARRACKS AT PHILADELPHIA DURING HOWE'S OCCUPATION

this folly to the last. Lord George Germain in England was only in part to blame. Burgoyne marched from Canada in June 1777, with a strong expeditionary force, to occupy Albany and put himself in touch with Howe who was expected to come up the Hudson. Driving the Americans under Gen. Arthur St. Clair out of Ticonderoga, and making his way through the deep woods with difficulty, he reached the Hudson at Fort Edward on July 30. Gen. Philip Schuyler, commanding the Americans in that quarter, retreated to Stillwater, 30m. above Albany, barricading the roads and impeding Burgoyne's progress. Unjustified dissatisfaction with his conduct led Congress to replace Philip Schuyler by Gen. Gates. On Aug. 13, Burgoyne despatched a force to Bennington, Vt., under the German colonel Friedrich Baum, to capture stores and overawe the country. On the 16th Baum was attacked by Gen. John Stark with the militia from the surrounding country, and was overwhelmed. Col. Breyman, marching to his relief, was also routed. The misfortune cost the British 1,000 men. Equally unfortunate was the fate of an expedition sent under Col. Barry St. Leger to co-operate with Burgoyne by way of the Mohawk Valley. On Aug. 16 he was met at Oriskany by Gen. Nicholas Herkimer and forced to retreat. Despite these disasters Burgoyne pushed south to Stillwater, where he was defeated by Gates's improvised army of continentals and militia in two battles on Sept. 10 (Freeman's Farm) and Oct. 7 (Bemis's Height). On the 17th he was forced to surrender. (See SARATOGA, BATTLES OF.) This disaster was followed by the alliance between America and France in 1778, and later by the addition of Spain and Holland to England's enemies—events of far-reaching importance.

A noteworthy movement, in 1778-79, was the expedition of George Rogers Clark, under the authority of the State of Virginia, against the British posts in the north-west. With a company of volunteers Clark captured Kaskaskia, the chief post in the Illinois country, on July 4, 1778, and later secured the submission of Vincennes, which, however, was recaptured by Gen. Henry Hamilton, the British commander at Detroit. In the spring of 1779 Clark raised another force, and recaptured Vincennes from Hamilton. This expedition did much to free the frontier from Indian raids, gave the Americans a hold upon the north-west, of which their diplomats probably took advantage in the peace negotiations, and later, by giving the States a community of interest in the western lands, greatly promoted the idea of union.

In 1778 Sir Henry Clinton succeeded Howe in the chief command in America. With fewer resources than his predecessor, he could accomplish practically nothing in the north. In June, 1778, he evacuated Philadelphia, with the intention of concentrating his force at New York. Washington, who had passed the winter at Valley Forge, overtook him at Monmouth, N.J., and in an action on June 28 both armies suffered about equal loss. Thereafter (except in the winter of 1779, at Morristown) Wash-

ington made West Point on the Hudson the headquarters of his army, but Clinton avowed himself too weak to attack him there. In 1779 he attempted to draw Washington out of the highlands, with the result that in the manoeuvres he lost the garrison at Stony Point, 700 strong, the position being stormed by Wayne with the American light infantry on July 16. During the summer Gen. J. Sullivan marched with a large force against the Indians (all the Iroquois tribes except the Oneidas and part of the Tuscaroras siding with the British during the war) and against the Loyalists of western New York, who had been committing great depredations along the frontier; and on Aug. 29 he inflicted a crushing defeat upon them at Newtown, on the site of the present Elmira. In addition several Indian villages and the crops of the Indians were destroyed in the lake region of western New York.

Meanwhile the co-operation of the French became active. In July Count Rochambeau arrived at Newport, R.I., occupied by the British from 1776 to the close of 1779. An unsuccessful attempt was made to drive them out in 1778 by the Americans assisted by the French admiral d'Estaing and a French corps. The year 1780 is also marked by the treason of Gen. Benedict Arnold (*q.v.*), and the consequent execution of Major André. Minor battles and skirmishes occurred until in Aug. 1781 Washington undertook the project of a combined American-French attack on Cornwallis at Yorktown, Va., the success of which was decisive of the war (*see p. 801*).

Campaign in Georgia.—The inadequate results of the British campaigns against the northern colonies in 1776 and 1777 led the home Government to turn its attention to the weaker colonies in the south. Operations in the north were not to cease, but a powerful diversion was now to be undertaken in the south with a view to the complete conquest of that section. Success there would facilitate further movements in the north. An isolated

WASHINGTON AND STEUBEN AT THE AMERICAN ENCAMPMENT AT VALLEY FORGE WHERE WASHINGTON, USING STEUBEN AS MILITARY INSTRUCTOR, PREPARED HIS ARMY FOR THE FINAL CAMPAIGNS

attack on Charleston, S.C., had been made by Sir Henry Clinton and Sir Peter Parker as early as June 1776, but this was foiled by the spirited resistance of Gen. William Moultrie; after 1778 the southern attempts, stimulated in part by the activity of the French in the West Indies, were vigorously sustained. On Dec. 29 of this year Col. Archibald Campbell with an expeditionary corps of 3,500 men from Clinton's army in New York, captured Savannah, Ga., defeating the American force under Gen. Robert Howe. In the following month he pushed into the interior and occupied Augusta. Gen. Benjamin Lincoln, succeeding Howe,

undertook to drive the British out of Georgia, but Gen. Augustine Prevost, who had commanded in Florida, moved up and compelled Lincoln to retire to Charleston. Prevost, making Savannah his headquarters, controlled Georgia. In Sept. 1779 he was besieged by Lincoln in conjunction with a French naval and military force under Admiral d'Estaing, but successfully repelled an assault (Oct. 9), and Lincoln again fell back to Charleston. In this assault Count Casimir Pulaski, on the American side, was mortally wounded.

The prestige thus won by the British in the south in 1779 was immensely increased in the following year, when they victoriously swept up through South and North Carolina. Failing to achieve any advantage in the north in 1779, Sir Henry Clinton, under instructions from his government, himself headed a combined military and naval expedition southward. He evacuated Newport, R.I. (Oct. 25), left New York in command of the German general Wilhelm von Knyphausen, and in December sailed with 8,500 men to join Prevost at Savannah. Cornwallis accompanied him, and later Lord Rawdon joined him with an additional force. Marching upon Charleston, Clinton cut off the city from relief, and after a brief siege compelled Lincoln to surrender on May 12. (*See CHARLESTON.*) The loss of this place and of the 5,000 troops included in the surrender was a serious blow to the American cause. The apparent submission of South Carolina followed. In June Clinton returned to New York, leaving Cornwallis in command, with instructions to reduce North Carolina also. Meanwhile an active and bitter partisan warfare opened. The British advance had been marked by more than the usual destruction of war; the Loyalists rose to arms; the Whig population scattered and without much organization formed groups of riflemen and mounted troopers to harass the enemy. Little mercy was shown on either side. The dashing rider, Col. Banastre Tarleton, cut to pieces (April 14, 1780) a detachment of Lincoln's cavalry, and followed it up by practically destroying Buford's Virginia regiment near the North Carolina border. On the other hand, daring and skillful leaders such as Francis Marion and Thomas Sumter kept the spirit of resistance alive by their sudden attacks and surprises of British outposts. Hanging Rock, Ninety-Six, Rocky Mount and other affairs brought their prowess and devotion into notice. By the month of Aug. 1780, with the main British force encamped near the North Carolina line, the field seemed clear for the next advance.

The threatening situation in the Carolinas alarmed Congress and Washington and measures were taken to protect the distressed section. Before Cornwallis could be brought to bay he was faced successively by four antagonists—Gens. Gates, Greene, Lafayette and Washington. They found in him the most capable and dangerous opponent of the war. Greene called him "the modern Hannibal." With Lincoln's surrender of nearly all the Continental soldiers in the south, a new force had to be supplied to meet the British veterans. Two thousand men, mainly the Maryland line, were hurried down from Washington's camp under Johann de Kalb; Virginia and North Carolina put new men into the field, and the entire force was placed under command of Gen. Gates. Gates marched towards Camden, S.C., and on Aug. 16 encountered Cornwallis near that place. Each army by a night march attempted to surprise the other, but the British tactics prevailed, and Gates was utterly routed. The reputation he had won at Saratoga was ruined on the occasion by over-confidence and incompetence; De Kalb was killed in the action. Gen. Greene, standing next to Washington as the ablest and most trusted officer of the Revolution, succeeded Gates. Cornwallis marched leisurely into North Carolina, but before meeting Greene some months later he suffered the loss of two detachments sent at intervals to disperse various partisan corps of the Americans. On Oct. 7, 1780, a force of 1,100 men under Major Patrick Ferguson was surrounded at King's Mountain, S.C., near the North Carolina line, by bands of riflemen under Cols. Isaac Shelby, James Williams, William Campbell and others, and after a desperate fight on the wooded and rocky slopes, surrendered. Ferguson himself was killed. On Jan. 17, 1781, Gen. Daniel Morgan was attacked at Cowpens, south-west of King's Mountain, by Col. Tarleton with

his legion. Both were leaders of repute, and a most stirring action occurred in which Morgan, with Col. William Washington leading his cavalry, practically destroyed Tarleton's corps. Despite the weakening his army suffered by these losses, Cornwallis marched rapidly through North Carolina, giving Greene a hard chase nearly to the Virginia line. On March 15 the two armies met at Guilford court house (near the present Greensboro, N.C.) and a virtually drawn battle was fought. The British, by holding their ground with their accustomed tenacity when engaged with superior numbers, were tactically victors, but were further weakened by a loss of nearly 600 men. Greene, cautiously avoiding another Camden, retreated with his forces intact. With his small army, less than 2,000 strong, Cornwallis declined to follow Greene into the back country, and retiring to Hillsborough, N.C., raised the royal standard, offered protection to the inhabitants, and for the moment appeared to be master of Georgia and the two Carolinas. In a few weeks, however, he abandoned the heart of the State and marched to the coast at Wilmington, N.C., to recruit and refit his command.

At Wilmington the British general faced a serious problem, the solution of which upon his own responsibility unexpectedly led to the close of the war within seven months. Instead of remaining in Carolina he determined to march into Virginia, justifying the move on the ground that until Virginia was reduced he could not firmly hold the more southern States he had just overrun. This decision was subsequently sharply criticized by Clinton as unmilitary, and as having been made contrary to his instructions. To Cornwallis he wrote in May: "Had you intimated the probability of your intention, I should certainly have endeavoured to stop you, as I did then as well as now consider such a move likely to be dangerous to our interests in the Southern Colonies." The danger lay in the suddenly changed situation in that direction; as Gen. Greene, instead of following Cornwallis to the coast, boldly pushed down towards Camden and Charleston, S.C., with a view to drawing his antagonist after him to the points where he was the year before, as well as to driving back Lord Rawdon, whom Cornwallis had left in that field. In his main object, the recovery of the southern States, Greene succeeded by the close of the year; but not without hard fighting and repeated reverses. "We fight, get beaten, and fight again," were his words. On April 25, 1781, he was surprised in his camp at Hobkirk's Hill, near Camden, by Lord Rawdon and defeated, both sides suffering about an equal loss. On May 22 he attempted to storm the strong British post at Ninety-Six but was repulsed; and finally on Sept. 8 he fought the last battle of the war in the lower southern States at Eutaw Springs, S.C. In the first part of the action Greene was successful after a desperate conflict; in the pursuit, however, the Americans failed to dislodge the British from a stone house which they held, and their severe loss in both engagements was over 500 men. The British lost about 1,000, one-half of whom were prisoners. Better success attended the American partisan operations directed by Greene and conducted by Marion, Sumter, Andrew Pickens, Henry Lee and William Washington. They fell upon isolated British posts established to protect the Loyalist population, and generally captured or broke them up. Rawdon found himself unable with his diminishing force to cover the country beyond Charleston; and he fell back to that place, leaving the situation in the south as it had been in the early part of 1780. On the American side, Greene was hailed as the deliverer of that section.

Virginia Campaign.—Cornwallis, meantime, pursued his Virginia project. Leaving Wilmington, N.C., on April 25, 1781, he reached Petersburg on May 20. There he found British detachments, 2,000 strong, composed of troops whom Clinton had sent down separately under Gens. Benedict Arnold and William Phillips to establish a base on the Chesapeake, as a diversion in favour of the operations of Cornwallis in the Carolinas. Virginia at the moment presented a clear field to the British, and they overran the State as far north as Fredericksburg and west to Charlottesville. At the latter place Jefferson, governor of the State, barely escaped capture by Tarleton's men. A small American force under Lafayette, whom Wayne reinforced during the summer, partially

checked the enemy. At Green Spring, near Jamestown Island, Lafayette boldly attacked his antagonist on July 6, but had to save himself by a hasty retreat. Early in August Cornwallis retired to Yorktown to rest and await developments. There he fortified himself, and remained until the American-French military and naval combination, referred to on p. 799, appeared and compelled his surrender. (*See YORKTOWN.*)

With this event war operations ceased. Preliminary articles of peace, signed on Nov. 30, 1782, were followed by a definitive treaty concluded on Sept. 3, 1783. Charleston, S.C., was evacuated late in 1782; New York on Nov. 25, 1783. The reasons of Great Britain's misfortunes and failure may be summarized as follows: Misconception by the home Government of the temper and reserve strength of her colonists, a population mainly of good English blood and instincts; disbelief at the outset in the probability of a protracted struggle covering the immense territory in America; consequent failure to despatch sufficient forces to the field; the safe and Fabian generalship of Washington; and finally, most decisive of all, the French alliance and European combinations by which at the close of the conflict Britain was without a friend or ally on the continent.

BIBLIOGRAPHY.—Though now sadly out of date, the most exhaustive reference work for this period is vol. vi. of Winsor's *Narrative and Critical History of America* (Boston, 1887). Its nine chapters, prepared by different writers, give a complete review of the struggle, both military and naval, and each closes with numerous illustrative notes, editorial criticisms and a full list of authorities. The volume is interspersed, far more extensively and richly than any other treatise on the war, with reproductions of contemporary plans, maps, documents, portraits and prints. Supplementing Winsor and bringing the material down to recent date is C. H. Van Tyne's *American Revolution* (Harper's "Am. Nation" Series, 1905), chap. xviii., on bibliographical aids and authorities. General histories of the war are mainly of American authorship, such as: George Bancroft's *History of the United States* (Boston, 1883-85) which, in spite of minor errors of fact and judgment, will remain standard; J. Fiske's *American Revolution* (Boston, 1891); Carrington's *Battles of the American Revolution* (1876) is a critical study by a military officer; B. J. Lossing's *Pictorial Field Book of the Revolution* (1850-59) is not always accurate, but preserves local traditions and details. Monographs on single events or campaigns abound: A. French, *The Day of Concord and Lexington* (1925); H. Murdock, *Bunker Hill*; Dawson's papers on Ticonderoga, "Storming of Stony Point," etc. (1866-); Johnston's "Campaign of 1776 around New York" (L.I. Hist. Soc., 1877), "Yorktown Campaign" (1881), etc.; Sargent's *Life of Major John André* (Boston, 1861), one of the best Revolutionary biographies; Gen. William Stryker's *Battles of Trenton and Princeton* (Boston, 1898); and *The Battle of Monmouth*; Justin Smith, *Struggle for the 14th Colony* (1907); and others mentioned in Winsor, Van Tyne and Channing. English works are Lord Mahon's *History of England*, vol. vi.; Sir George O. Trevelyan's *American Revolution*, a new study of cabinet and parliamentary politics of the period, with review of the military events; Hon. J. W. Fortescue, *History of the British Army*, vol. iii. (1902); H. Belcher, *The First American War*, Vol. i., ii.; F. J. Huddleston, *Gentleman Johnny Burgoyne*; H. Nickerson, *The Turning Point of the Revolution*; Lecky, *A History of England in the 18th Century* (1903); Burgoyne's *State of the Expedition from Canada in 1777* (1780). The naval warfare is best studied in G. W. Allen, *A Naval History of the American Revolution* (1913); C. O. Paulin, *Navy of the American Revolution* (1906); Captain Mahan, *Major Operations of the Navies in the War of Independence* (1913).

(H. P. J.; C. H. VAN T.)

THE WAR AT SEA

The largely economic origin of the American Revolution took on a prominently maritime aspect in its early phases. Heavily in debt from recent wars, England was also faced with a constantly increasing demand for overseas markets and marine expansion, on account of the "industrial revolution" through which she was then passing. Beginning in 1764 a series of laws were passed by parliament having in view both the raising of revenue through taxing the sea-borne imports of the colonies, and the favouring of English maritime trade by discriminations against colonial shipping. Laws looking solely to the latter object had been in existence for many years, but custom had given them little attention, and a large prosperous colonial merchant marine had grown up on a technically illegal trade and had become an important element in the economic structure of the colonies. Consequently the enforcement of these "Navigation Acts" was the cause of much hardship

and resentment in America. As early as 1764 a British schooner so engaged was fired on in Rhode Island waters. In 1769 the sloop "Liberty," similarly employed, was seized and burnt at Newport. Such incidents became more common as British coercive measures increased, and when war finally broke there was a popular uprising on the sea quite comparable to that on land.

The onset of the Revolution found the colonies with no naval forces whatever, but with a large maritime population, and many merchant vessels commonly employed as the principal means of transport for both domestic and foreign trade. This merchant service was familiar not only with the sea, but also with warfare. Colonial ships and seamen had taken a prominent part in the large naval expeditions against Cartagena and Louisburg, had engaged in privateering during the more recent French war, and even during peace had habitually gone armed as a protection against pirates. In 1775 it was therefore natural that considerable numbers of colonial merchant vessels should turn to privateering; a general practice which was continued on a large scale until the close of the war, under legal authorization of individual colonies and of the Continental Congress. Records are incomplete but indicate that well over 2,000 private armed vessels were so employed during the course of the war, carrying upwards of 18,000 guns and 70,000 men. In addition, several of the colonies organized "State" navies which also engaged in preying upon hostile commerce. These operations were on such a scale that they must be regarded as a primary American military effort of the war. Together with the operations of a few "Continental" vessels they constituted the only sustained offensive pressure brought to bear by the Americans which materially affected the attitude of the British people towards peace. Such injury was done British commerce as to increase insurance rates to unprecedented figures, to seriously reduce available sources of revenue and to alarm the sea-coast population.

In its military-naval aspect the war followed two distinct phases; the first ending when France allied herself with the colonies in 1778, until which time Britain had no foreign enemy, and was free to concentrate her whole strength against the Americans. In the second phase England ultimately had to contend against the fleets of France, Spain and Holland, and her consequent inability to meet the naval necessities in American waters was a major influence in the final and decisive campaign ending at Yorktown. With the large navy available during the first three years of the Revolution it was repeatedly urged by Viscount Barrington, the British secretary for war, that: "Conquest [of the colonies] by land is unnecessary when the country can be reduced first by distress, and then to obedience by our marine totally interrupting all commerce and fishery, and even seizing all ships in the ports with very little expense and less bloodshed." Instead of adopting such strategy the British naval forces were used primarily in direct support of army operations and in the protection of their own maritime commerce.

The pressing want of munitions for the Colonial army was the chief impulse in the creation of regular American naval forces. This need caused Benedict Arnold, formerly a sea captain, to march from the siege of Boston, and in association with Ethan Allen to make a surprise capture of the well-stocked stronghold of Ft. Ticonderoga on Lake Champlain, so early as May 10, 1775. The seemingly minor event had far-reaching results. Not only were munitions obtained, but the prompt seizure of all lake watercraft also gave to the colonies control of the only practicable line of communications from the St. Lawrence river to the Hudson valley. At first provoked by this overt act the Continental Congress at Philadelphia, then debating ways of forming a constitutional union with England, soon reversed its attitude, voted general defensive measures, and appointed George Washington commander-in-chief of the army. A few weeks after taking command of the Continental army besieging Boston, Washington organized a naval force to prey upon the British water communications of that port, and in this way essential munitions were obtained. In Oct. 1775 Congress voted funds for the first units of a small fleet of eight vessels which sailed from the Delaware on Feb. 17, 1776, under Commodore Esek Hopkins. The objective was Nassau

in the Bahama islands, where a quantity of powder was known to be stored. This was captured on March 3, and the valuable munitions taken in to New London. Meantime the British army under Howe had evacuated Boston and gone by sea to Halifax. Correctly estimating the future probabilities, Washington marched to New York and also provided for the defence of Lake Champlain. For the campaign of 1776 the British plan was to isolate New England by capturing and holding the line of the Hudson river. With this end in view, Howe, heavily reinforced, sailed in June for New York, while other forces undertook an advance via Lake Champlain. Here Arnold had retreated after an unsuccessful attack on Quebec, and had actively begun the construction of a fleet to retain control of the lake.

During the summer a British army of nearly 13,000 men advanced from Quebec to the lake but was compelled to halt until a sufficient naval force could be constructed to cope with Arnold's rapidly growing fleet. This they were able to do after some months through the assistance of artisans from their ships in the St. Lawrence river, and by reassembling on the lake a large vessel whose dismantled parts had been transported in small boats from Quebec. In a series of naval actions on Oct. 11, 12 and 13, Arnold's fleet of 15 vessels was destroyed. Meantime Howe had gained possession of the lower Hudson, but the season was now so late that the British command on Lake Champlain decided to abandon further operations until spring, and retreated into Canada. When in June of the following year Burgoyne renewed the advance from the north, Howe had shifted his operations by sea to the vicinity of Philadelphia, and Burgoyne was forced to surrender at Saratoga (Oct. 17, 1777) from lack of support. Thus had Arnold's fleet, by delaying the British army for nearly a year, contributed largely to the decisive battle of Saratoga which proved to be a turning point in the war.

Impressed by the evidence of American strength given at Saratoga, and wishing to recover her losses to England in previous wars, France entered into a treaty of alliance with the United States in Feb. 1778. The event marked the beginning of an entirely new phase in the war. Henceforth naval power was to be employed on a great scale and to affect vitally military operations in America, as well as the course of European history, and the fate of valuable possessions from the West Indies to the East Indies. Herein can be considered at any length only those events which bore directly on the American Revolution.

A French fleet under d'Estaing sailed from Toulon in April 1778, bound for America. Advance news of its coming caused a hasty evacuation of the Delaware by the British fleet then acting in support of the army occupying Philadelphia. Fearing to risk the loss of the army in the event of meeting a superior French fleet at sea, the British command decided to march the troops, bereft of their line of supply, by land to New York, where a junction with the fleet was again made. D'Estaing appeared off the port a few days later, but having missed the opportunity of a decisive victory in the Delaware, he sailed for Newport in accordance with an understanding made with Washington. While preparations were in progress at Newport for a joint attack by Americans and French upon the British garrison of 6,000 troops, the British fleet approached, having been reinforced from England. D'Estaing hastily abandoned the land operations and put to sea to meet them. A partial engagement ensued, followed by a gale which so damaged the ships as to persuade the French admiral to go to Boston for extensive repairs (Aug. 1778). On this account the American army before Newport was withdrawn. Meantime a second and more powerful French fleet had been fitted out at Brest with the object of indirectly assisting their overseas naval forces by holding the main strength of the British navy to its home waters. In July 1778 a large but indecisive fleet action was fought off Ushant. Under cover of these major operations Captain John Paul Jones of the "Continental Navy" with a small squadron based on French ports, carried on a series of raids against British coastal shipping.

At this period of history considerations of weather during the winter season usually caused the transfer of naval operations from the Western Hemisphere to the West Indies, which held the

further attraction of being the richest of the world's commercial regions in value of products. Therefore when d'Estaing sailed from Boston in Nov. 1778, his destination was the Caribbean sea, for which locality most of the British fleet in America also sailed on the same day. The latter took 5,000 troops with them, thus greatly reducing the land forces opposed to the Continental army. During the next four years the West Indies were the scene of a large-scale naval war, the forces on each side being often augmented from home, and in the case of the French fleet, by Spanish reinforcements. D'Estaing was unsuccessful off St. Lucia in two attacks (Dec. 1778) upon the main British fleet, but, while the latter was guarding a trade convoy, during the following summer, he captured St. Vincent and then Grenada where an indecisive naval action was fought upon the return of the British fleet (July 1779). Meantime in the autumn of 1778 the British had sent a small expedition from New York, under naval convoy, to Savannah, which place was taken. These operations were extended to the neighbourhood of Charleston during the following year, and attracted the attention of d'Estaing. Arriving off Savannah from the West Indies with his whole fleet in Aug. 1779, he failed in an attempt to retake the place. Nevertheless upon receiving news of the Savannah affair, the British Gen. Clinton at New York was so concerned over the safety of his diminished army in the north that he abandoned Newport in order to concentrate his forces against possible French attack.

The summer of 1779 also saw the ill-starred "Penobscot Expedition." A British military-naval force having occupied what is now Castine, Me., the Massachusetts government undertook to dislodge it. A fleet of 40 vessels including three of the Continental navy and 20 transports, in all carrying 200 guns and 3,000 men sailed from Boston and began its attack on the British position on July 25. Fighting continued afloat and ashore until Aug. 13, when a superior British naval squadron arrived from New York and put the Americans to rout.

John Paul Jones, operating from French bases with a small squadron, made a cruise around the British Isles from Aug. to Oct. 1779. Many prizes were taken and the British frigate "Serapis" was captured after a memorable duel with the American flagship "Bon Homme Richard." The success of these operations was greatly aided by the fact of the absence in distant waters of practically the whole naval strength of Great Britain, and by the operations in the English channel of a large combined French and Spanish fleet in support of a threatened invasion of England from France.

On the American coast the year 1780 saw the inception of the British policy of conquering the Carolinas which involved such a division of forces as to bring about the ultimate loss of the war. An army detachment escorted by naval forces was sent from New York and captured Charleston in May. These operations were placed in some jeopardy by the arrival of a French squadron with 6,000 troops at Newport in July, but this was offset by British naval reinforcements reaching New York a day later. The British operations in the Carolinas were also covered by the activity in the West Indies of a large naval force under Admiral Rodney, which had been recently sent out from England. Three indecisive actions were fought, near Martinique in April and May 1780, against the French fleet under Admiral Guichen, which was finally reinforced by a Spanish squadron.

Not meeting with the success which had been anticipated, Cornwallis, commanding the southern British army in America decided upon a movement into Virginia where naval support could be utilized to better advantage. Meantime on the James river, Benedict Arnold (then under British allegiance) had been ravaging the country, and at the request of Washington the French squadron at Newport had proceeded to the Chesapeake; but after an indecisive action with a British squadron (March 1781), had returned to Newport. Cornwallis joined Arnold on March 20, at Petersburg, with the intention of undertaking vigorous offensive operations in Virginia. But the commander-in-chief, Gen. Clinton, who was at New York, felt that the forces available were insufficient for such an undertaking, and ordered Cornwallis to intrench himself in a strong position which would control a fleet

anchorage. Cornwallis complied by moving to Yorktown, where he arrived on Aug. 22 with 7,000 troops. It should be observed here that England's ability to support her forces in America at this stage was seriously impaired by Holland joining the alliance against her. In Aug. 1781 a severe naval action was fought in the North sea between the Dutch and British fleets. England's naval forces were further involved in the defence of Gibraltar, Minorca and India.

The joint military-naval combination which brought about the surrender of Cornwallis and the virtual end of the war in America,

BY COURTESY OF THE N.Y. HISTORICAL SOCIETY

THE BRITISH FLEET UNDER RODNEY DEFEATS DE GRASSE, 1782
The French fleet under De Grasse attempted the capture of Jamaica. Rodney pursued and defeated him off the island of Dominica in an engagement that detracted from rather than added to the reputations of both officers. A large part of the French fleet escaped

was very unusual. It involved the timely concentration at Yorktown of widespread forces; a co-ordination of effort which was very difficult to accomplish with the means of communication and the slow mobility of that period. The most important element in the situation was naval control, since Cornwallis' supplies and reinforcements must come by sea and Washington's army near New York could not be moved with sufficient celerity to the critical area except by utilizing water transport on Chesapeake bay. The co-operation of the main French fleet, which for several years had been operating against the British fleet in the West Indies, was essential, and its aid was requested by both Washington and Rochambeau. Admiral de Grasse concurred in the plan and sailed from Haiti on Aug. 25, 1781, with 28 ships of the line. Gaining advance information of this move through intercepted messages, the British admiral also left the West Indies and was the first to reach the Chesapeake, but not being certain of de Grasse's destination, continued on to New York. Here it became evident from the southerly movements of the united armies of Washington and Rochambeau, that Yorktown was the main Franco-American objective, and Admiral Graves hastily sailed on Aug. 31 for that locality.

Meantime Admiral de Grasse had arrived in the Chesapeake and had stationed cruisers in the James river to prevent Cornwallis from escaping to the south. On Sept. 5 the British fleet of 19 ships of the line appeared off the Chesapeake entrance where it was partially defeated by 24 French ships present. Admiral Graves remained in the vicinity for the next seven days, still hoping for an opportunity to reach Yorktown and assist in its defence, but the French fleet, increased to a total of 36 ships of the line by the arrival of the Newport squadron, took up an intervening position inside the bay. On Sept. 13 Graves therefore departed for New York. The control of the Chesapeake being then undisputed, the allied troops were transported by water from the north to Williamsburg whence they marched to the investment of Yorktown. Here, with his sea communications completely severed, Cornwallis surrendered on Oct. 19, 1781; virtually ending the war on the American continent.

The French admiral, having rendered this vital service to his ally, now returned to the West Indies, whither he was followed by Hood. In Jan. and Feb. 1782 he conquered St. Christopher, in spite of the most determined opposition of the British. The next purpose of the French was to combine with the Spaniards for an

attack on Jamaica. Sir George Rodney, having returned to his command with reinforcements, baffled this plan by a series of operations which culminated in the battle of April 12, 1782. This, combined with the success of the British in withstanding repeated naval attacks against Gibraltar, took the heart out of the French and Spaniards and made them ready for peace. After preliminary articles had been signed in Nov. 1782, the naval campaign between British and French squadrons in India continued until June 1783.

In retrospect the American Revolution is seen to have developed from small beginnings into one of the greatest naval wars in history. During its progress the early issues of colonial maritime rights and independence became subordinated in European eyes to that of the control of the then commercially very valuable West Indies, and other objects. The fleet operations which in a few weeks decided the fate of Yorktown, and of the American cause, were merely incidental to the vast naval campaign carried on over a period of five years in Caribbean, European and Indian waters.

BIBLIOGRAPHY.—Captain A. T. Mahan's, *The Major Operations of the Navies in the War of American Independence* (1913) is the most authoritative, comprehensive and impartial work available; Gardner W. Allen's *A Naval History of the American Revolution* (1913), is a careful and more detailed account of American naval operations. See also Henry Cabot Lodge, *The Story of the Revolution* (1898); Sir W. Laird Clowes, *The Royal Navy: A History* (1897-1903), and Louis Edouard Chevalier, *Histoire de la Marine française pendant la Guerre de l'Indépendance Américaine* (1877). (D. W. K.)

AMERICAN SMELTING AND REFINING COMPANY, THE, was first organized in 1899 as a consolidation of companies engaged in the business of custom lead smelting and refining. In 1902 a further consolidation was made with the interests of the Messrs. Guggenheim, who thereafter were in executive charge of the company. Under their administration the company went largely into custom copper smelting and refining and later into custom zinc smelting. It also became an important miner of metals.

The company in 1927 operated lead, silver, copper and zinc mines in the United States, British Columbia, Mexico and Peru. It had 16 smelters and refineries in the United States, five smelters in Mexico and one in Peru. During the year 1927 its plants produced 1,479,899 oz. gold; 80,671,759 oz. silver; 476,988 tons lead; 536,830 tons copper; 52,170 tons spelter.

The balance sheet as of Dec. 31, 1927, was as follows:

ASSETS	
Property and investments	\$131,642,493.26
Cash and government securities	35,382,817.83
Inventories and other miscellaneous assets	60,710,459.85
Total assets	<u>\$227,735,770.94</u>
LIABILITIES	
FUNDED DEBT AND CAPITAL STOCK:	
Bonds outstanding	\$ 47,591,400.00
Preferred stock outstanding	50,000,000.00
Common stock outstanding	60,998,000.00
	<u>\$158,589,400.00</u>
Current and miscellaneous liabilities	19,546,484.75
Reserves	22,552,661.87
Profit and loss surplus	<u>27,047,224.32</u>
	<u>\$227,735,770.94</u>

(E. L. Ne.)

AMERICAN SOCIETY FOR THE PREVENTION OF CRUELTY TO ANIMALS, THE, was organized in 1866 and incorporated in New York State. Its charter gives it special prosecuting powers within that jurisdiction. Directly or indirectly, it is the parent of all humane societies in the United States and of many abroad. Its administrative work through its hospital and shelters is chiefly confined to New York city.

The society was founded by Henry Bergh, who, when secretary of the American Legation in Russia, became incensed over the ill-treatment of animals on the streets and decided to start an anti-cruelty work in America. On his way home he studied the methods of the R.S.P.C.A. in England. There were at that time in America no effective laws for animal protection and no organ-

ization to enforce such as existed. Bergh spent his remaining 22 years in tireless activity on behalf of animals. After his death the society, with endowments by him and others, was developed administratively and is undoubtedly the wealthiest and strongest body of its kind in the world. A dispensary and hospital was erected in 1912 and doubled in 1927. Animal shelters are maintained in various parts of the city, and offices are kept open at all hours to answer emergency calls.

AMERICAN SOCIETY OF NATURALISTS is an "association of working naturalists for the discussion of methods of investigation and instruction, laboratory technique and museum administration, and other topics of interest to investigators and teachers of natural history; and for the adoption of such measures as shall tend to the advancement and diffusion of the knowledge of natural history in the community." It was founded at Springfield, Mass., in 1883. With the development of special societies in the different biological fields the position of the naturalists has become more general, and since 1908 the programmes have related particularly to the subject of organic evolution. Meetings are held annually and consist of an afternoon symposium and an evening address by the president, ordinarily on some general aspect of evolution. Membership in 1927 was 438.

AMERICAN SUGAR REFINING COMPANY, THE, incorporated in New Jersey, U.S.A., on Jan. 10, 1891, succeeded the Sugar Refineries Company, organized in 1887. The capital stock in 1891 was \$50,000,000, was increased in 1892 to \$75,000,000, and in 1901 to \$90,000,000. The stock consists of 450,000 shares of 7% cumulative preferred and 450,000 shares of common. In 1922 \$30,000,000 of 15-year 6% debenture bonds were issued. The stockholders number approximately 24,000, of whom about one-half are women.

The company, including its subsidiaries, owns five refineries for manufacturing refined sugar from raw cane sugar, obtained chiefly from Cuba, Porto Rico, Philippines and Louisiana. The refineries have a daily melting capacity of about 16,000,000 lb. It supplies more than one-fifth of the refined sugar consumed in the United States. It has two modern raw sugar factories at Cunagua and Jaronu in Cuba, with 500 sq.m. of land, 191 m. of railroad and the capacity to produce 600,000,000 lb. of raw sugar each year.

The Brooklyn Cooperage Company, a subsidiary, is one of the largest manufacturers of barrels in the world. (A. B. Wm.)

AMERICAN TELEPHONE AND TELEGRAPH COMPANY, THE. The first telephone company was formed in 1876 when the inventor, Alexander Graham Bell, assigned to the Bell Patent Association his first two telephone patents. On July 9, 1877, this first association was succeeded by the Bell Telephone Company, first as a trusteeship and later as an incorporation. This company in turn was succeeded, in 1879, by the National Bell Telephone Company, which represented the Bell interests until the American Bell Telephone Company was organized on March 20, 1880, and that in turn became the parent Bell company until Dec. 1, 1899, when the directors voted to transfer all the assets of the company, both in stock and in property, to the already existing American Telephone and Telegraph Company.

After this transfer, accomplished by an exchange of stock, the American Telephone and Telegraph Company became the central or parent company of the Bell system, which now furnishes telephone service in every State in the United States of America. This company owns more than 93% of the common stock of the regional operating companies, called the Associated companies, owns and operates directly long-distance lines interconnecting these regional companies and maintains a central organization for scientific research, standardization of methods and materials, patents and aid in financing. Some of these services are rendered by separate companies controlled by the American Telephone and Telegraph Company, such as the Bell Telephone laboratories, a research organization, and the Bell Telephone Securities Company, which informs and aids the purchaser of securities of the Bell system. The American Telephone and Telegraph Company also provides for telephone equipment through the Western Electric Company, which it controls through stock ownership.

The American Telephone and Telegraph Company's charter,

granted in 1885, stated that the purpose of the company was to build and operate telephone lines for long-distance communication connecting the regional operating companies, including "the constructing, buying, maintaining and operating of lines of electrical communication within the State of New York, and from points within the State of New York to points anywhere in the United States, in Canada and Mexico, and by cable and other appropriate means anywhere through the rest of the world."

The outstanding stock of the American Telephone and Telegraph Company, including instalment payments on stock not yet issued, was in Dec. 1927 \$1,142,289,200, par value. It was owned by 423,580 stockholders, of whom not one owned as much as 1% of the stock. The average holding was 26 shares. The total of all Bell system stocks, including instalments, was \$1,351,939,840, par value, owned by more than 525,000 stockholders. The total assets of the Bell system amounted to \$3,457,467,311, of which \$3,013,985,120 represented telephone plant.

The Associated Bell companies own and operate 13,726,000 telephones in the United States. There are, in addition, 4,639,000 telephones, owned by nearly 9,000 independent telephone companies to which the Bell system gives telephone connection over its lines under contract. This makes a total of more than 18,365,000 telephones served by the Bell system. This service is rendered over a network of more than 63,500,000 m. of wire, of which 56,823,000 m. are Bell owned. During the year 1927 the Bell system made a daily average of 55,195,000 telephone connections throughout the United States network.

In the Bell system, all told, there are more than 353,000 employees, drawing a total monthly payroll of over \$45,000,000.

By the steady improvement of telephone service the Bell system is increasing the range and improving the efficiency of American business and social life, while the extension of the service by trans-oceanic telephony, which began with the opening of telephone service between New York and London on Jan. 7, 1927, will connect the American telephone system with the systems of a large part of Europe.

During the five years ending in 1927 construction expenditure for additions, betterments and replacements amounted to \$1,800,000,000. During the next five years it was expected that further expansion of the telephone business, as well as further improvements in the service, would require the expenditure for construction of approximately \$2,000,000,000. (W. S. G.)

AMERICAN TOBACCO COMPANY, THE, one of the world's largest manufacturers of tobacco, cigarettes and other tobacco products. So far as its name is concerned it goes back to 1890, and so far as its corporate organization is concerned goes back to Oct. 1904 when, under the laws of New Jersey, the old American Tobacco Company, the Consolidated Tobacco Company and the Continental Tobacco Company, were merged. The general offices of the company are in New York city; its manufacturing is done in Brooklyn, N.Y., Richmond, Va., Reidsville, N.C., Durham, N.C., and, through a subsidiary called Nashville Tobacco Works of which it owns all the stock, in Nashville, Tenn. It has warehouses for the gathering and storage of leaf tobacco in Virginia, North Carolina, South Carolina, Kentucky, West Virginia and Tennessee. It owns a substantial majority of the preferred and common stocks of the American Cigar Company, which is engaged in the manufacture and sale of cigars.

The growth of the cigarette business in America, as compared with other tobacco products, has been very marked, and it is estimated that the American Tobacco Company has approximately one-third of the cigarette business. It is difficult to form an estimate as to the other branches of the business, but in variety of output the American Tobacco Company exceeds any of its competitors.

The outstanding capitalization consists of \$52,699,700 of preferred stock, issued at par, \$40,242,400 of common stock of the par value of \$50 a share, which has voting rights with the preferred stock, and \$57,401,800 of common stock B which receives the same rate of dividend and has the same rights in liquidation as the common stock, but has no voting power. The total surplus at the end of 1927 was \$39,421,241.27.

AMERICAN WAR OF 1812: see WAR OF 1812.

AMERICAN WOOLEN COMPANY, THE, one of the world's largest manufacturers of cloth, was incorporated in 1899. It acquired eight companies manufacturing woollen goods and began operations early in the same year. Through stock ownership the company controls and operates the National and Providence Worsted Mills, Providence, R.I.; Woollen and Worsted Mills, Inc., American Woollen Company of New York, American Woollen Company of Kentucky, Shawshen Mills and Webster Mills of Massachusetts. Altogether, the company and its subsidiaries have owned and operated some 60 mills situated in New England, New York and Kentucky. Toward the close of 1925, 55 of these plants were in operation. Until 1923 the management carried on a policy of expansion, the practice being to continue each new mill's identity until it cleared all obligations and then consolidate it with the parent concern. In 1925-26 the wool market suffered a severe decline; in the latter year the woollen and worsted industries of the country operated at about 60% capacity, and in 1927 the company closed several of its less important mills. At the end of 1926 the company's net working capital was about \$60,000,000; current assets, \$75,954,000, a ratio to liabilities of nearly 5 to 1; authorized capital stock, \$40,000,000 common and \$50,000,000 cumulative preferred. The executive offices of the company are in Boston, Massachusetts. (A. G. Pr.)

AMERICA'S CUP, an international yacht-racing trophy first won by the schooner "America" of the New York Yacht club in 1851. In 1850 an English merchant suggested to friends in the United States that one of the fast New York pilot boats be sent to England in the ensuing year to take part in a yacht race to be held during the time of the Great Exhibition at London. In response to this invitation, George Steers, of New York, designed and built for Commodore J. C. Stevens, of the New York Yacht club, the wooden-keel schooner-yacht "America," about 100ft. long and of 170 tons displacement. Crossing the Atlantic in July, 1851, this vessel took part on Aug. 22 in a race open to the yachts of all nations. In sailing the course, which was around the Isle of Wight, the "America" defeated the entire fleet of 14 vessels of the Royal Yacht squadron, thereby winning a silver cup valued at £100. In 1857 the owner of the "America" gave this cup to the New York Yacht club, to be held thereafter as an international yacht-racing trophy. From 1870, when the American schooner "Magic" defeated the British schooner "Cambria," to 1920, when the American yacht "Resolute" defeated Sir Thomas Lipton's Shamrock IV, 13 attempts, all unsuccessful, have been made by the British to recapture the America's Cup.

See Ahmed John Kenealy, *Yacht Races for the America's Cup, 1851-1893* (1893); W. S. Quigley, *The America's Cup* (1903); Herbert Lawrence, *The America's Cup Races* (1914); and Alfred Johnson, "Harvard Men and the America's Cup," *Harvard Graduates' Magazine*, vol. xxxv, p. 53-66 (1926).

AMERICUS, a city of Georgia, U.S.A., about 71 m. S.S.W. of Macon, on the Dixie highway, the Central of Georgia railway, and the Seaboard Air Line; the county seat of Sumter county. The population in 1920 was 9,010, and in 1930 it was 8,760. Americus is the trading centre of one of the richest agricultural regions of the South. Cotton is still an important crop, yielding about 30% of the agricultural income of the county, but diversification is increasing, and other crops (especially corn, oats, hay, peaches, pecans, melons and vegetables) are becoming relatively more important. Some farmers produce their entire supply of feed and food, except coffee, sugar and salt. There is a creamery in the city, and several factories. Americus was settled in 1832 and was chartered as a city in 1855.

AMERIND or AMERINDIAN, a word coined by Major J. W. Powell, director of the bureau of American Ethnology, to designate the aboriginal inhabitants of the American continent. The term "American Indian" being too cumbersome for general use, was frequently abbreviated to "Indian," thereby leading to confusion with the inhabitants of the East Indies. See *Handbook of American Indians North of Mexico* (1907) s.v. Amerind.

AMERIND FOLKLORE offers an exceptional field to the student, since its psychological factors are racially homogeneous and practically untouched by intrusive influences. Its cultural

complexes exhibit subtle intergradings all the way from simple hunting societies to town-building agricultural co-operative communities. The continuity of aboriginal cultures in Mexico with those of the United States, and the easily discoverable environmental influences, afford a unique opportunity for the study of diffusion by contact. Much has been lost by neglect, but there is compensatory gain in the employment of native Amerind scholars in collection and interpretation.

The basis of Amerind exoteric lore is the tribal origin and migration myth, which can be found in the form of simple hero cycles, more or less ritualized lays, or, as in the case of the New Mexican Pueblos, in epic form comparable in literary value to anything produced at similar cultural levels in Europe. Other exoteric material concerns itself with the explanation of natural phenomena and with social and economic practices. One of the most interesting groups of such rites and legends deals with the origin of wealth as "capital," with the invention of "interest" and the distribution of economic surplus.

Amerind myth in general refers chiefly to cultural rather than military exploits, and deals with heroes who seek prestige through social benefits conferred and the attainment of magical power. The esoteric myths relate to the methods by which such power is attained, its use in curing the sick, ensuring the food supply and the increase and security of the tribe. The happy ending of any Amerind tale is the certainty of having attained this "medicine," although in tales not primarily magical, all the usual primitive story elements can be found: lovers who die for love, tests for proving love, the devoted male friends, the animal helper, the magic talisman or fetish, the dull boy who becomes chief or shaman, and the beginnings of a Cinderella myth. Among magical happenings which have no esoteric significance are the animal wife, the star or moon maiden, deific twin brethren, other-world adventures, dwarfs, ogres and such supernaturals as underwater people, wind and thunder people. Ghosts play an important part in both exoteric and esoteric myth. Communication with them is a constant resort, and there are societies of personators of the ancestral spirits. Virgin birth, sacrificial death and resurrection occur in connection with vegetation rites, along with animal impersonators and masked metamorphic powers of nature. Rites and ceremonials achieve a high level of aesthetic presentation, approaching early Greek dance-drama and sacerdotal comedy. Music, poetry, colour design, dance and dramatic dialogue are not inferior to the sacred lore of other tribes at similar cultural levels.

The Amerind's concept of his universe is animistic, the *wakonda* or animating spirit being thought of as resident in some degree in everything, but concentrating in important natural objects, such as the sun, the sea, the buffalo. Personalization of these centres of spiritual energy is still rather a figure of speech than a belief among Amerinds, and a general concept of a Great Spirit, Father All Father, Universe Man, is found in the more advanced tribes.

(M. A.)

For examples of Amerind Folklore, see the works of Frank Hamilton Cushing and Alice Cunningham Fletcher. For Mexican Folklore, see Carl Lumholtz, *Unknown Mexico* (1903).

AMERSFOORT, town in the province of Utrecht, Holland, on the navigable Eem, and a junction station 14m. by rail N.E. by E. of Utrecht. Pop. (1900) 19,089, (1927) 35,959. It is situated among sandy heaths and woods. The Koppelpoort, an old gateway, ends an avenue bordering the canal. The large plain church of St. George dates from the 13th century. There is a Jansenist church, with seminary attached, a town hall and a court of primary jurisdiction. Its chemical and tobacco industries received a great impetus during Holland's neutrality (1914-18).

AMERSHAM, market town of south Buckinghamshire, England, placed in the narrow valley of the Misbourne stream, giving access to Wendover and Aylesbury via the Chiltern hills. Population of rural district (1931) 29,250. At the time of the Domesday survey Amersham was divided into six holdings. The manor was held by Geoffrey de Mandeville. Henry VIII. granted it to Sir John Russell, one of whose descendants, the earl of Bedford, conveyed it to the Drake family in 1638. Amersham was formerly a borough by prescription, but lost its privileges in 1832. The

church of St. Mary is almost entirely Perpendicular, and has a beautiful south porch and brasses of the 15th, 16th and 17th centuries. The town has flour mills and breweries; and straw-plaiting and lace making survived until the end of last century. In modern times Amersham has developed as a residential centre, being served by the Met. and G.C. Joint Railways.

AMERY, LEOPOLD CHARLES MAURICE STENNETT (1873–), British politician, was born at Gorakhpur, North West Provinces, India, Nov. 22, 1873, and was educated at Harrow and Balliol college, Oxford. He was elected a fellow of All Souls college in 1897, and, after travelling for a year in the Near East, in 1899 joined the staff of *The Times*, London, and acted as chief correspondent to that paper during the first year of the South African War (1899–1900), remaining associated with it till 1909; during this period he edited and wrote the greater part of *The Times History of the South African War*. He began his political career in 1903, as a strong advocate of imperial preference and tariff reform and, having contested in the Unionist interest seats at Wolverhampton and Bow and Bromley, was elected in 1911 M.P. for the Sparkbrook division of Birmingham. During these years he also travelled extensively in Canada, Australia, New Zealand, South Africa and other parts of the British empire. From 1914 to 1916 he served with the British army, first in France and later in the Near East, and from 1917 to 1918 was a secretary of the War cabinet on the personal staff of the secretary for war and of the Imperial War cabinet, and a member of the inter-allied military staff at Versailles. In Jan. 1919 he became under-secretary for the Colonies and in 1921 parliamentary and financial secretary to the Admiralty. From Oct. 1922 to Jan. 1924 he was first lord of the Admiralty in the Unionist cabinet. In Nov. 1924 he became secretary of state for the Colonies, and in July 1925 also secretary of state for dominion affairs. In this latter capacity he took part in the Imperial Conference of 1926 and made a tour round the British dominions in 1927–28.

He has published various works, including *The Problem of the Army* (1903); *Fundamental Fallacies of Free Trade* (1906); *The Great Question* (1909); *Union and Strength* (1912).

AMES, FISHER (1758–1808), American statesman, orator and political writer, was born at Dedham, Mass., on April 9, 1758. He graduated at Harvard college in 1774, and began the practice of the law at Dedham in 1781, but eventually abandoned that profession for the pursuit of politics. He was a prominent member of the Massachusetts convention which (Feb. 1788) ratified for that state the Federal Constitution, and in the same year in the lower house of the state legislature, he distinguished himself by his eloquence and readiness in debate. During the eight years of Washington's administration (1789–97) he was a prominent Federalist member of the national House of Representatives. On April 28, 1796, when the Republicans, hostile to the Jay Treaty, were on the point of holding up the appropriation necessary for its execution, Ames made what has been considered the greatest speech of his life and secured the passage of the appropriation. When Washington retired from the presidency, Congress voted him an address and chose Ames to deliver it. Ames was one of the group of New England ultra-Federalists known as the "Essex Junto," who opposed the French policy of President John Adams in 1798, and were conspicuous for their British sympathies. He died on July 4, 1808.

His writings and speeches, which display great fertility of imagination, were collected and published, with a memoir of the author, in 1809, by the Rev. Dr. J. T. Kirkland. A more complete edition was published by the statesman's son, Seth Ames, in 1854.

AMES, JAMES BARR (1846–1910), American educator and legal scholar, was born in Boston, Mass., on June 22, 1846. He graduated from Harvard university in 1868 and from its law school in 1872. Entering the faculty of Harvard as instructor in history, he was made associate professor of law in 1873 and professor of law in 1877. In 1895 he was appointed dean of Harvard law school, a post which he occupied with distinction until his death 15 years later. Because of his profound learning and rare power as a teacher he exercised marked influence both upon the development of law and upon legal instruction. He grasped the

relation of law and morals at a time when current legal thinking insisted upon contrasting them or upon absolutely divorcing them. In consequence, his ideas as to what ought to be the law have prevailed rather than those of his contemporaries who conceived that it was unnecessary to look outside of the positive legal materials. For the use of students he published valuable case books on the law of torts, equity jurisdiction, negotiable paper, suretyship, admiralty, pleading at common law and other divisions of law. His *Essays in Legal History* (1912), collected and published after his death, constitute an enduring contribution to historical jurisprudence. He died at Wilton, N.H., on Jan. 8, 1910.

See Charles W. Eliot, "James Barr Ames," *Harvard Law Review*, vol. xxiii, p. 321–324 (1910); and Joseph H. Beale, "James Barr Ames: His Life and Character," *ibid.*, p. 325–329.

AMES, JOSEPH (1689–1759), English author, was born at Yarmouth on Jan. 23, 1689. He wrote an account of printing in England from 1471 to 1600, *Typographical Antiquities* (1749). Ames disregarded printed lists and consulted the title-pages of the books themselves. An interleaved copy of the work with many notes in the author's hand is now in the British Museum. Editions of his works were published with added information by William Herbert (1785–90), and T. F. Dibdin (1810–19). Ames's occupation is variously given. It is uncertain whether he was a ship-chandler, a patten-maker, a plane-iron-maker, or an ironmonger; but he led a prosperous life at Wapping, and amassed valuable collections of antiquities. He died on Oct. 7, 1759. His other works are catalogues of English printers, of the collection of coins which belonged to the earl of Pembroke, of some 2,000 English portraits, and *Parentalia* (1750), a memoir of the Wrens, undertaken in conjunction with Sir Christopher Wren's grandson, Stephen Wren. Part of his correspondence in bibliography is included in Nichols's *Literary Anecdotes and Illustrations*.

AMES, JOSEPH SWEETMAN (1864–), American physicist, was born in Manchester, Vt., on July 3, 1864. He received his education at Johns Hopkins university from which he graduated in 1886 and received the degree of doctor of philosophy in 1890. He was assistant and associate in physics there in 1888–93 and associate professor from 1893 to 1899 when he was made professor of physics. In 1901 he was appointed director of the physical laboratories. In 1930 he became president of Johns Hopkins university.

His published works include *Theory of Physics* (1897), *Manual of Experiments in Physics* (1898), *Free Expansion of Gases* (1898), *Prismatic and Diffraction Spectra* (1898), *Elements of Physics* (1900), *Induction of Electric Currents* (1900), *Text-book of General Physics* (1904) and *The Constitution of Matter* (1913).

AMES, OAKES (1804–1873), American manufacturer, capitalist and politician, was born in Easton, Mass., on Jan. 10 1804. As a manufacturer of shovels, with his father and his brother Oliver (1807–77), he amassed a large fortune. From 1863 to 1873 he was a Republican member of the national House of Representatives. As a member of the committee on railroads he became interested in the project to build a trans-continental railway, connecting the eastern States with California. In 1865 he took charge of the work, and to him more than to any other one man the credit for the construction of the Union Pacific railway was due. The execution was effected largely through a construction company, the Crédit Mobilier Company of America. In disposing of the stock of this company, Ames, in 1867–71, sold shares to members of Congress at a price much below what they eventually proved to be worth. This gave rise in 1872–73 to a congressional scandal. After an investigation by a committee of the House, which recommended the expulsion of Ames, a resolution was passed on Feb. 28 1873, "that the House absolutely condemns the conduct of Oakes Ames . . . in seeking to secure congressional attention to the affairs of a corporation in which he was interested, and whose interest directly depended upon the legislation of Congress, by inducing members of Congress to invest in the stocks of said corporation." Many have since attributed this resolution to partisanship, and the influence of popular clamour. In 1883 the legislature of Massachusetts passed a resolution vindicating Ames. He died at North Easton, Mass., on May 8 1873.

See CRÉDIT MOBILIER OF AMERICA and the references there given. For a defence of Oakes Ames, see *Oakes Ames, A Memorial Volume* (Cambridge, Mass., 1884).

AMES, WILLIAM (1576–1633), English Puritan divine and controversialist, known as AMESIUS, was born at Ipswich, Suffolk, and died at Rotterdam. Ames was educated at Christ's College, Cambridge, and became a fellow of his college. He raised a great stir in 1609 by a sermon denouncing the "heathenish debauchery" attending the feast of St. Thomas. He was obliged eventually to leave England and spent the rest of his life in Holland, where he engaged in numerous theological controversies. He was for a short time chaplain to Sir Horatio Vere in Holland, then professor of theology at Franeker, Friesland (1622–33), and had just removed to Rotterdam when he died.

The tracts which he wrote against Grevinchovius he collected in *Coronis ad Collationem hagiensem*, which was prepared in view of the Synod of Dort 1618–19. His works include *Medulla theologiae*, a manual of Calvinistic doctrine for his students; *De conscientia eius iure et casibus*; *Fresh suit against Ceremonies*, posthumously published, which is said to have made Richard Baxter a nonconformist; and Latin commentaries on the Psalms and St. Peter's epistle.

See John Quick's ms. *Icones Sacrae Anglicanae*; *Life* by Nethenus, prefixed to collected edition of Latin works (Amsterdam, 1658); Winwood's *Memorials*, vol. iii. pp. 346–47; Neal's *Puritans*, i. 532; Fuller's *Cambridge (Christ's College)*; Hanbury's *Hist. Memorials*, i. 533; *Collections of the Massachusetts Historical Society*, vol. vi. (4th series, 1863), pp. 576–577.

AMES, WINTHROP (1871–), American theatrical producer, was born in North Easton, Mass., on Nov. 25, 1871. He graduated at Harvard in 1895, and spent the following year in special study at the university. For eight years he edited and published art and architectural works in Boston. Then followed a year abroad where he studied the continental drama, and in 1905 he became manager, in association with Loren F. Deland, of the Castle theatre, Boston, where for three years they conducted a very notable stock company. In 1909, he became director of the New theatre (now the Century) in New York city, where he made the first attempt in recent years to establish a repertory theatre. With the passing of the New theatre, he began, in 1912, independent production and management, erecting two theatres, the Little and the Booth. He contributed a wide variety of productions, among them *Snow White*, the first play given in New York city especially for children. He also revived the Gilbert and Sullivan operas.

AMES, a city of Story county, Iowa, U.S.A., in the centre of the state, 35 m. N. of Des Moines; on two lines of the Chicago and North Western, and on the Fort Dodge, Des Moines and Southern (electric) railway. The population, nearly all native white, increased from 2,422 in 1900 to 6,570 in 1920 and 10,261 in 1930 (Federal census). The town was laid out in 1864 and incorporated in 1869. It was named after Oakes Ames, one of the owners of the railway. It is the headquarters of the State Highway Commission, which employs about 1,000 men over the state. A commission-manager form of government was adopted in 1920.

Ames is the seat of the Iowa State College of Agriculture and Mechanic Arts, established in 1858, as a "state agricultural college and model farm," and broadened in scope in 1862 to meet the conditions of the Congressional "land-grant" act of that year. In 1927 the college property was valued at \$8,750,869. The central campus of 125 ac. is a beautiful park. An inner plaza of 20 ac., containing a campanile with a chime of ten bells cast in Loughborough, England, is surrounded by stately buildings of white Bedford stone. Around these is an outer ring of shops and laboratories. Abutting on the central campus are farms for teaching and experiment in agronomy, animal husbandry, bee culture, dairy husbandry, horticulture, poultry raising, veterinary science, and other branches, comprising in all nearly 2,000 acres. There are 70 buildings for college purposes. The meats laboratory includes an amphitheatre with 500 seats; greenhouses contain 33,000 sq.ft. under glass; the automobile laboratory is 80 by 207 ft.; the new library (1925) has a capacity for 250,000 volumes; the main Home Economics building (1927; 400 ft. long) is supplemented

by the Nursery School near by, where the work in child care and training is conducted, and by three well planned houses for the courses in home management. The engineering division of the college is as large as the division of agriculture. The administrative and teaching staff numbers more than 500, and the annual enrolment of students is more than 5,000, adding more than 50% to the resident population of the city.

AMESBURY, a market town, Wiltshire, England, lying in the rich and well-wooded valley of the Avon, amid the chalk downs of Salisbury Plain, 8 m. N. of Salisbury; population of rural district (1931) 16,883. The neighbourhood is very rich in remains of prehistoric man, among which Stonehenge (*q.v.*), 1½ m. W., is the greatest surviving megalithic structure in the British Isles. On a hill overlooking the village is a large earthwork, "the Ram-parts," which perhaps marks a preceding settlement. At Amesbury (Ambresberia, Aumbresbery) a witenagemot was held in 932, while (*c.* 980) Ethelfrida, queen dowager of Edgar, erected here a nunnery in expiation of the murder of her stepson. At the time of Domesday Amesbury was a royal manor. From the 12th century the nunnery was attached to the abbey of Fontevrault, and was enriched by royal charters and private gifts. The grant of a weekly market and fair dates from 1317. The church of St. Mary is largely Early English, with some richly decorated windows. Amesbury abbey, built by Inigo Jones for the dukes of Queensberry, stands close to the village.

Pipeclay abounds in the neighbourhood, and in the 17th century Amesbury was famous for its pipes. Its interests are now largely agricultural, frequent sheep fairs being held. The town profits from the permanent army camps in the vicinity (particularly from Larkhill) and from the tourist traffic visiting Stonehenge and other objects of interest on the plain. Amesbury is served by a branch railway, running to the camp at Bulford, joining the S.R. between Andover and Salisbury.

AMESBURY, a town of Essex county, in north-east Massachusetts, U.S.A., on the Merrimac river, between the city of Newburyport and the New Hampshire border, 43 m. N. of Boston. It is served by the Boston and Maine railroad, and is connected by electric line with Haverhill and Newburyport and summer resorts on the coast. The town covers a land area of about 13 sq. miles. The surface is hilly. The population in 1930 was 11,899. The principal manufactures are automobile bodies and accessories, hats, bent glass, abrasives, castings and shoes; the total factory output in 1927 was valued at \$19,772,024.

Amesbury was settled in 1642, as a part of Salisbury, and in 1654 became practically independent, although not legally a township until 1666. It was named (1667) after the English town in Wiltshire. Quakers settled here as early as 1701. Josiah Bartlett (1729–95) a signer of the Declaration of Independence, was born here. Shipbuilding was an important industry in the 18th and especially in the first quarter of the 19th century. A nail factory, one of the earliest in the country, was built in 1796. The manufacture of iron began about 1710; of hats in 1769; of carriages in 1800; and of cotton goods in 1812. Amesbury was the home of John G. Whittier from 1836 to 1892, and many of his poems describe the surrounding country and the life of the community.

See Joseph Merrill, *History of Amesbury* (Haverhill, 1880); S. T. Pickard, *Whittier-Land: a Handbook of North Essex* (Boston, New York, 1904).

AMETHYST, a violet or purple variety of quartz used as an ornamental stone. The name is generally said to be derived from the Gr. *α*, "not" and *μεθύσκεν*, "to intoxicate," expressing the old belief that the stone protected its owner from strong drink. It was held that wine drunk out of a cup of amethyst would not intoxicate. The colour of amethyst is usually attributed to the presence of manganese, but as it is capable of being much altered and even discharged by heat it has been referred by some authorities to an organic source. On exposure to heat, amethyst generally becomes yellow, and much of the cairngorm or yellow quartz of jewellery is said to be merely "burnt amethyst."

The amethyst was used as a gem-stone by the ancient Egyptians, and was largely employed in antiquity for intaglios. It is now used for episcopal rings. It is a very widely distributed mineral, but

fine, clear specimens fit for cutting as ornamental stones are confined to comparatively few localities. Such crystals occur either in cavities in mineral-veins and in granitic rocks, or as a lining in agate geodes. Many of the hollow agates of Brazil and Uruguay contain a crop of amethyst-crystals in the interior. Much fine amethyst comes from Russia, especially from near Mursinka in the Ekaterinburg district.

AMETROPIA. The normal refractive condition of the eye is known as emmetropia. Any departure from this condition is called ametropia. Like a camera, the eye is provided with a lens and a light-sensitive membrane, the retina. The cornea and the transparent substances which fill the eyeball aid the refractive power of the lens. In an ideal eye at rest, parallel rays come to a clear focus on the retina. Although only about 2% of properly examined eyes exactly meet this standard, the majority of normal eyes closely approach it. When, however, due to defects in the refractive mechanism, parallel rays do not come to a clear focus on the retina of a resting eye, the condition is called ametropia. Such defects may be abnormalities in length of the eyeball or irregularities in the curvature of the cornea or lens, and the resulting varieties of ametropia are called myopia, hyperopia and astigmatism. (See ASTIGMATISM.)

AMHARA, the central province of Abyssinia. The chief town, Gondar (*q.v.*), by which name the province is also known, was the residence of the negus negust, or emperor, of Abyssinia from the middle ages up to 1854.

AMHARIC. The most important language spoken in Abyssinia (*q.v.*) is Amharic, which belongs to the Semitic family (*q.v.*), but has been greatly modified by Hamitic influences. The order of the words is that usual in Hamitic speech, the verb coming last and subordinate words preceding those with which they are associated. Laryngeal consonants are absent and the system of writing, which dates from the 2nd century A.D., is remarkable for the great number of forms required, since each of the 26 consonants has seven vowel forms, while a special sign is added to mark the softened pronunciation in vogue. Very considerable phonetic modifications have taken place, resulting often in a total change of form. As regards syntax, the governed noun is placed after the genitive, while the attributive relative clause is placed before its substantive. Few traces remain of the feminine forms or of the ancient plural of the noun. Not more than half of the vocabulary—after allowing for phonetic modifications—can be found to tally with that of other Semitic languages. (See C. Armbruster, *Initia Amharica*.)

AMHERST, JEFFREY AMHERST, BARON (1717-97), British field-marshal, served in Germany and the Low Countries as aide-de-camp to Gen. (Lord) Ligonier, and was present at Dettingen, Fontenoy and Roucoux. He then served on Cumberland's staff, and took part with the duke in the later campaigns of the Austrian Succession war, in the battle of Val, and the North German campaign of 1757, including the battle of Hastenbeck. In 1758 William Pitt gave Amherst command of an expedition to attack the French in North America.

The first victory of the expedition, the capture of Louisbourg (July 26 1758), was followed by other successes, and Amherst was given the chief command of all the forces in the theatre of war. In the campaign of 1759 Amherst's own share was the capture of Ticonderoga and Crown Point, while Ft. Niagara fell to another column, and Quebec was taken by Wolfe. In 1760 a concentric march on Montreal was carried out with complete success. Amherst was immediately appointed governor-general of British North America. His conduct of the operations against the Indians under Pontiac was, however, far from being as successful as his generalship against regular troops; and he returned to England in 1763.

He was created a peer in 1776, was promoted to the rank of general in 1778, and aided in suppressing the Gordon Riots of 1780. For the rest of his active life, with a short interval in 1782-83, he was commander-in-chief. In 1796 Lord Amherst, who had retired from the Horse Guards in 1795, was made field-marshal; and he died Aug. 31 1797 at "Montreal," his residence in Kent. Amherst college (*q.v.*) was named in his honour.

AMHERST, WILLIAM PITT AMHERST, EARL (1773-1857), governor-general of India, was the nephew of Jeffrey, Baron Amherst, and succeeded to his title in 1797. Upon his return from an abortive mission to China in 1816, his ship, the "Alceste," after a cruise along the coast of Korea and to the Luchu Islands, was wrecked on a sunken rock in Gaspar Strait.

The ship in which he returned to England in 1817 touched at St. Helena, and he had several interviews with the Emperor Napoleon (see Ellis's *Proceedings of the Late Embassy to China*, 1817; McLeod's *Narrative of a Voyage in H.M.S. "Alceste,"* 1817). Lord Amherst held the office of governor-general of India from Aug. 1823 to Feb. 1828. The principal event of his government was the first Burmese war of 1824, resulting in the cession of Arakan and Tenasserim to Great Britain. He was created Earl Amherst of Arakan in 1826. Upon his return to England, he lived in retirement till his death in March 1857.

See A. Thackeray and R. Evans, *Lord Amherst* ("Rulers of India" series), 1894.

AMHERST, a village and district in the Tenasserim division of Lower Burma. The village is about 30m. S. of Moulmein. It was founded by the British in 1826 on the restoration of the town of Martaban to the Burmese, and named in compliment to the governor-general of India of that day; but in 1827 the headquarters were transferred to Moulmein. Amherst is now merely a fishing village and a bathing-place for Moulmein. For a description of Amherst district see BURMA.

AMHERST, county town, Cumberland county, port of entry in Nova Scotia, Canada, at the head of Chignecto bay and on the Canadian National railway, 138m. from Halifax. Pop. (1931) 7,450. It is in a rich agricultural and mining district, contains numerous factories, and has an especially large trade in lumber and ship-building. It distributes goods, and exports railway carriages, engines, boilers, stoves, etc.

AMHERST, a town of Hampshire county, Mass., U.S.A., in the central part of the State, with a population in 1930 of 5,888 (Federal census). The village of Amherst, about 100m. W. of Boston, is situated on a plateau within a rampart of hills on the east side of the Connecticut river; and is served by the Boston and Maine and the Central Vermont railways. It is a quiet, academic village, with shady streets and attractive homes.

Amherst college (*q.v.*) stands on a hilltop which commands a broad outlook. The Massachusetts agricultural college (incorporated 1863; opened 1867) has a campus of 700 ac. about a mile north of the village centre, and a demonstration farm of 755 ac., 6m. farther north. The enrolment in the college in 1926-27 was 570 in the courses leading to the degree of bachelor of science, and 406 in the several shorter courses which are offered to meet the needs of men and women who cannot spend four years in study.

The town seems to have been settled in 1731. It was originally part of Hadley, was incorporated as a "district" in 1759, and as a town in 1775. It was named after Gen. Jeffrey Amherst (1717-97). Noah Webster lived in the village (1812-22) while working on his *Dictionary*. Emily Dickinson (*q.v.*) and Helen M. Fiske (Helen Hunt Jackson, see JACKSON, HELEN MARIA) were born there.

See William Seymour Tyler, *A History of Amherst College* (1896), and Carpenter and Morehouse, *The History of the Town of Amherst* (1896).

AMHERST COLLEGE, one of the best known of the so-called small New England colleges, is situated in a beautiful amphitheatre of hills in the town of Amherst (*q.v.*), Massachusetts. It was founded in 1821 but did not receive its charter until 1825. Like most early colleges of New England, it was established with the chief aim of preparing students for the ministry. Although soon after its founding the college began to widen the scope of its activities, it has preserved to the present day the idea of a liberal as opposed to a vocational training. Consistent with this purpose it has never added graduate or professional schools, adhering strictly to a course leading to the degree of A.B. with an ever real, though diminishing, emphasis upon the ancient classics.

The college grew rapidly for a score of years, but then experi-

enced a period of reaction which nearly cost the institution its life. There was a revival under the presidency of the eminent geologist, Edward Hitchcock (1845-54) and another reaction at the time of the Civil War. Since then its history has been one of quiet, but steady growth.

In 1927 it numbered 750 students and a faculty of 70 teachers. The material resources of the college amounted to \$3,000,000

BY COURTESY OF AMHERST COLLEGE

CHAPEL ROW, AMHERST COLLEGE, SHOWING THE ORIGINAL BUILDINGS

in buildings and equipment, and to \$6,600,000 in invested funds. Its buildings consisted of four dormitories, five halls devoted to administration and instruction, two large laboratories, one of which is divided between physics and chemistry (a new chemistry laboratory being in process of construction), and the other between biology and geology, a library, chapel, church, a gymnasium equipped with a natatorium and squash courts, a large indoor athletic field and skating rink, a music building and an observatory. The library, thoroughly modern in its appointments, contained approximately 150,000 books. The observatory is equipped with two domes, one housing a telescope with an 18in. Clark objective, and the other with a 7in. telescope (Clark objective) for student use. The geological and biological building contains the famous Hitchcock ichnological collection, the Adams shells, a part of the Audubon collection of birds, an extensive mineral collection including a rare assortment of meteorites, and fossil groups arranged to illustrate the theory of evolution. About 100ac. of land are devoted to athletic sports, the larger portion being used for intramural sports upon which the college lays an ever increasing emphasis.

For its size (6,000 graduates in the first hundred years), the college has had an exceptional number of graduates of distinction, among others being Henry Ward Beecher and Calvin Coolidge. It has been eminent in foreign missionary work, especially in the field of education. The Syrian Protestant college (now the American university) of Beirut, Syria, was founded by Daniel Bliss of the class of 1852; the Doshisha, the first institution of higher learning in Japan, by Joseph Neesima of the class of 1870; and Robert college, in Constantinople, owed a very large part of its early success to President George Washburn of the class of 1855.

AMHURST, NICHOLAS (1697-1742), English political writer, was born at Marden, Kent, Oct. 16 1697, and died at Twickenham, April 12 1742. He was educated at Merchant Taylors' School and St. John's College, Oxford. At Oxford he wrote many satirical poems on university life, and in 1719 was expelled. Some of his satirical papers were published in 1726, as *Terrae Filius: or the secret history of the University of Oxford*. In London he became a pamphleteer against Walpole's Government, editing *The Craftsman*, which was the organ of Lord Bolingbroke and William Pulteney. Amhurst was in prison for a short time in 1737 for suspected libel. When his political friends overthrew Walpole in 1742 they appear to have forgotten Amhurst.

AMIAK: see NILOTES.

AMIANTHUS, a name applied to the finer kinds of asbestos (*q.v.*), in consequence, it is said of the mineral being unaffected by fire (Gr. *ἀμιαντος*, undefiled). Some of the finest amianthus, with long silky flexible fibres, occurs in the district of the Tarentaise in Savoy. According to Dr. J. W. Evans, the ancient amianthus, derived mostly from Karystos in Euboea and from Cyprus, was probably a fibrous serpentine, or chrysotile (now called locally *παμπρόπετρα*, or cotton-stone).

See *Mineralogical Mag.*, vol. xiv. no. 65 (1906), art. by J. W. Evans.

AMICABLE NUMBERS (also known as *amiable numbers* or, less commonly, as *agreeable numbers*), two integers each of which is equal to the sum of the aliquot parts (*q.v.*) of the other. For example, 220 and 284 are amicable numbers, for the aliquot parts of 220 are 1, 2, 4, 5, 10, 11, 20, 22, 44, 55 and 110, the sum of which numbers is 284. Similarly, the sum of the aliquot parts of 284 (that is, of 1, 2, 4, 71 and 142) is 220. These two numbers are mentioned by the Greek arithmetician, Iamblichus (*c.* 325). Mathematicians have discovered 63 other pairs.

AMICE (Lat. *amictus*, from *amicire*, to wrap round), sometimes called *humeral* (from *humerus*, shoulder), a liturgical vestment of the Western Church. It is a rectangular linen cloth, with a small cross sewn or embroidered in the middle, which is wrapped round the neck, shoulders and breast. It is first laid on the head, then allowed to fall on the shoulders, and finally folded round the chest and tied with the strings attached for that purpose. It is worn under the alb, except at Milan and Lyons, where it is put on over it. The vestment was at first a perfectly plain white cloth, but from the 10th century onwards it was often richly embroidered, and the custom arose of decorating the upper border with an "apparel" forming a sort of stiff collar which appeared above the chasuble or dalmatic.

The Latin word *amictus* was applied to any wrap-like garment, and, according to Father Braun, the liturgical amice originated in the ordinary neck-cloth worn by all classes of Romans. The first record of its liturgical use is in the 1st Roman Ordo (8th century), when it was worn only with the dalmatic and was known as the *anabologium* (*anagolaium*, *anagolagium*, Gr. *ἀναβόλαιον*), a name it continued to bear at Rome till the 11th century. In the 9th century it spread to other countries: it is mentioned in an inventory of vestments given by Abbot Angilbert (d. 814) to the monastery at Centula (St. Riquier) and in the *de clericorum institutione* of Hrabanus Maurus (*c.* 820). The amice was worn first simply as a shoulder-cloth, but towards the end of the 9th century the custom grew up of putting it on over the head and of wearing it as a hood, either while the other vestments were being put on or, according to various local uses, until the celebrant reached the altar. This ceased at Rome in the 15th century, when the apparel disappeared; but two relics of it survive—(1) in the vesting directions of the Missal and the priest's prayer, "Place on my head the helmet of salvation," etc., (2) in the ordination of subdeacons, when the bishop lays the vestment on the ordinand's head with the words "Take the amice, which symbolizes discipline over speech."

The amice was rejected with the other "Mass vestments" in England at the Reformation. Its use has, however, been revived in many Anglican churches. (See **VESTMENTS**.) A vestment akin to the amice is worn in the Armenian and some other oriental churches, but it is unknown to the Orthodox Eastern Church.

See Joseph Braun, S.J., *Die liturgische Gewandung*, pp. 21-56 (Freiburg im Breisgau, 1907), and bibliography to the article **VESTMENTS**.

AMICI, GIOVANNI BATTISTA (1786-1863), Italian astronomer and microscopist, was born March 25 1786, at Modena and died at Florence, April 10 1863. His name is best known for the improvements he effected in the mirrors of reflecting telescopes and especially in the development and construction of the microscope.

AMICIS, EDMONDO DE (1846-1908), Italian writer, was born at Oneglia, in Liguria, Oct. 21 1846. He was educated for the army, and fought at the battle of Custoza in 1866. In 1867 he became director of the *Italia Militare*, Florence. In the following year he published *La Vita Militare*, a book of

sketches of military life. After his retirement from the army in 1870 de Amicis travelled in Europe and Africa, and published a number of travel books which were long popular. The most important of these are his descriptions of London (1874), Spain (1873), Holland (1874), Constantinople (1877) and Morocco (1875). He died suddenly of heart disease at Bordighera on March 12, 1908.

Among his other wellknown works are: *Il Romanzo d'un Maestro*, and the widely read *Il Cuore* (translated into English as *An Italian Schoolboy's Journal*). Later works are *La Carozza di tutti*, *Memorie, Speranze e glorie*, *Ricordi d'infanzia è di scuola*, *L'Idioma gentile*, and a volume of short stories, *Nel Regno dell' Amore*.

AMICUS CURIAE, a term used primarily in law, signifying a person (usually a member of the Bar) who, having special knowledge but not being engaged in the action, intervenes during its hearing to give information for the assistance of the court, either upon some fact relevant to the issue or upon a point of law, such as the effect of a local custom, the precedent of some decided case, etc.

AMIDES (*Acid-Amides*), chemical compounds which may be considered as derived from ammonia by replacement of its hydrogen with acyl residues, which are the characteristic groups of organic acids, derivable from these by removal of the acidic hydroxyl group or groups; the substances produced are known as primary, secondary or tertiary amides, according to the number of hydrogen atoms replaced. Of these compounds, the primary amides of the type $R \cdot CO \cdot NH_2$ are the most important, the group $\cdot CO \cdot NH_2$ being called the amido group. They may be prepared by the dry distillation of the ammonium salts of the acids (A. W. Hofmann), by the partial hydrolysis of the nitriles, by the action of ammonia or ammonium carbonate on acid chlorides or anhydrides, or by heating the esters (*q.v.*) with ammonia. They are solid crystalline compounds (formamide excepted); the lower members of the series are soluble in water, the solubility, however, decreasing as the carbon content of the molecules increases. They are easily hydrolysed, breaking up into organic acids and ammonia or when boiled with acids or alkalis. They form compounds with hydrogen chloride when this gas is passed into their ethereal solution; these compounds, however, are very unstable, being readily decomposed by water. On the other hand, they show faintly acid properties, since the hydrogen of the amido group can be replaced by metals to give such compounds as mercury acetamide $(CH_3CONH)_2Hg$. Nitrous acid decomposes them, with elimination of nitrogen and the formation of the corresponding acid:

When distilled with phosphoric anhydride they yield nitriles. By the action of bromine and alcoholic potash on the amides, they are converted into amines containing one carbon atom less than the original amide, a reaction which possesses great theoretical importance (A. W. Hofmann), and is also of industrial interest in the Badische synthesis of indigo (*q.v.*), for in accordance with Hofmann's reaction phthalimide is converted by alkali hypochlorite into anthranilic acid:

Formamide, $H \cdot CONH_2$, is a liquid readily soluble in water, boiling at about $195^\circ C$ with partial decomposition. Acetamide, $CH_3 \cdot CONH_2$, a white deliquescent crystalline solid, which melts at $82-83^\circ C$ and boils at $222^\circ C$, is usually prepared by distilling ammonium acetate. Benzamide, $C_6H_5 \cdot CONH_2$, crystallizing in leaflets which melt at $130^\circ C$, is prepared by the action of ammonium carbonate on benzoyl chloride. It yields a silver salt which with ethyl iodide forms benzimido-ethyl ether, a behaviour which points to the silver salt as being derived from the tautomeric imidobenzoic acid:

AMIDINES, the name given to compounds of general formula $R \cdot C(:NH) \cdot NH_2$, which may be considered as derived from the acid-amides, $R \cdot CO \cdot NH_2$ (*see AMIDES*) by replacement of oxygen by the divalent imino ($=NH$) group. They may be prepared by the action of ammonia or amines on imide chlorides or on thiamides; by the action of ammonium chloride or

hydrochlorides of amines on nitriles; by condensing amines and amides in presence of phosphorus trichloride; by the action of hydrochloric acid on acid-amides; and by the action of ammonia or amines on imino-ethers. They are colourless crystalline bases, which are unstable; they readily take up the elements of water (when boiled with acids or alkalis), yielding amides and ammonia. On dry distillation they yield nitriles and ammonia. With β -ketonic esters, $HO(CH_2)_3C \cdot CH \cdot CO_2R$, they yield oxyppyrimidines.

Formamidine, $HC(:NH)NH_2$, is only known in the form of its salts, the crystalline hydrochloride being obtained by the action of ammonia on the hydrochloride of formimido-ethyl ether.

Acetamidine, $CH_3C(:NH) \cdot NH_2$, is alkaline in reaction, and readily splits up into acetic acid and ammonia when warmed with acids. Its hydrochloride crystallizes from alcohol in colourless deliquescent prisms.

Benzamidine, $C_6H_5 \cdot C(:NH)NH_2$, forms colourless crystals which melt at $75-80^\circ C$.

AMIEL, HENRI FREDERIC (1821-1881), Swiss philosopher and critic, was born at Geneva Sept. 27, 1821. He studied philosophy at Berlin 1844-48. In 1849 he was appointed professor of aesthetics at the academy of Geneva, and in 1854 became professor of moral philosophy. These appointments, conferred by the democratic party, deprived him of the support of the aristocratic party which comprised nearly all the culture of the city. This isolation inspired the one book by which Amiel lives, the *Journal Intime*, which, published (2 vols. 1882-84) after his death, obtained a European reputation. It was translated into English by Mrs. Humphry Ward, and attracted many readers, partly because of the high praise given to it by Matthew Arnold, and partly because it interpreted many lonely souls to themselves. He died in Geneva, on May 11, 1881.

BIBLIOGRAPHY.—*See Life of Amiel* by Mlle. Berthe Vadier (Paris, 1885); Paul Bourget, *Nouveaux essais* (Paris, 1885); E. Scherer, introd. to the *Journal* and in *Études sur la litt. contemp.* (vol. viii.).

AMIENS, north France, capital of the department of Somme, on the left bank of the Somme, 81m. N. of Paris on the Northern railway to Calais. Pop. (1926) 82,215. Though involved in the World War and severely bombarded, the city retains its pre-war aspect. The old town occupies the low-lying area between the arms of the rivers Somme and Avre. The site of the ancient ramparts is occupied by boulevards; and suburbs, themselves bounded by another line of boulevards, have arisen beyond these limits, while the city also extends to the right bank of the Somme. The busy quarter lies between the river and the railway. The older quarter is situated directly on the Somme; its narrow and irregular streets intersected by the eleven arms of the river and skirted on the north by the canal derived therefrom.

Amiens occupies the site of the ancient *Samarobriua* capital of the Ambiani, from which it probably derives its name. At the beginning of the 4th century Christianity was preached there by St. Firmin, its first bishop. Its territory formed the mediaeval countship of Amienois, and early in the 12th century the citizens profiting by rivalry of count and bishop gained a charter of enfranchisement. The fief became a dependency of the French crown in 1185. In 1435, by the treaty of Arras it fell to the dukes of Burgundy, until 1477. Surprised by the Spaniards in 1597, the city was recaptured from them after a long siege by Henry IV. Till 1790 it was the capital of the Government of Picardy (*q.v.*). The famous treaty between Great Britain, France, Spain and Holland which took its name from Amiens was signed here in March 1802. In the Franco-German War (*q.v.*) Amiens, after an important action, fell into the hands of the Prussians on Nov. 28, 1870. In the World War the city was taken by the Germans on Aug. 30, 1914; but after the battle of the Marne the front was established some 20m. eastwards, where it remained till 1918. Amiens then became the first concentration point for British troops disembarking at Boulogne in 1914, and the first air-craft park was established here. It remained of high importance on the lines of communication and in March 1918 the Germans made a great effort to break through between the British and French armies at the Amiens salient. They advanced to with-

in eight miles of the town, which was evacuated by civilians and bombarded daily by heavy guns. The cathedral was struck nine times, and the roof pierced. Other buildings were damaged, and much havoc done in the Rue de Beauvais. Reconstruction, however, proceeded apace after the war. Amiens has the park or Promenade de la Hotoie to the west and several fine squares, notably the Place Longueville and the Place St. Denis with the statue of the famous 17th century scholar Charles Ducange.

The cathedral of Notre Dame (*see* ARCHITECTURE: *Romanesque and Gothic Architecture in France*; and CATHEDRAL) is one of the finest Gothic churches in France. Erected on the plans of Robert de Luzarches, chiefly between 1220 and 1288, it consists of a nave, nearly 140ft. in height, with aisles and lateral chapels, a transept with aisles, and a choir (with deambulatory) ending in an apse surrounded by chapels. The total length is 469ft., the breadth 216ft. The façade, which is flanked by two square towers, has three decorated portals, the central portal having a remarkable statue of Christ of the 13th century; they are surmounted by two galleries, the upper one containing 22 statues of the kings of Judah in its arcades, and by a fine rose-window. A slender spire rises above the crossing. The southern portal is remarkable for a figure of the Virgin and other statuary. The interior contains beautifully carved stalls and a flamboyant choir-screen, and is remarkable for the height of the nave and the boldness of the columns supporting the vaulting. Of the other churches of Amiens, St. Germain (15th century) has good stained glass. The *hôtel de ville*, begun 1550, a belfry of the 14th and 18th centuries and several old mansions are of interest. The learned associations of Amiens include the *Société des Antiquaires de Picardie*, by whom the museum was built in 1854-64, and the early prehistoric collections illustrate the classic area of the Somme.

The city is the seat of a bishop, a prefect, a court of appeal and a court of assizes, and headquarters of the II. Army Corps. There are also tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce. The textile industries, celebrated since the middle ages, include velvet, cotton, wool, silk, hemp and flax-spinning, hosiery and a variety of mixed fabrics. Though seriously affected by the World War the wool and textile industries have regained their pre-war conditions. Manufactures of machinery and chemicals, and printing, dyeing, and iron-founding are also carried on. Market gardens, known as *hortillonnages*, intersected by small canals derived from the Somme and Avre, cover a considerable area north-east of Amiens; and the city trades in vegetables, grain, sugar, wool, oil-seeds and in the duck-pasties and macaroons for which it is renowned. A very important fair for all species of merchandise is held annually.

AMIENS, BATTLE OF (1918). This is the name for the offensive of the British 4th and French 1st Army under Sir Douglas Haig's orders, an offensive which, launched by surprise on Aug. 8, 1918, and coming close after the Allied counterstroke on the Marne (*see* WORLD WAR and MARNE, SECOND BATTLE OF THE), inaugurated the unbroken tide of advance which culminated in the Armistice, on Nov. 11, 1918. After the German spring offensive had been finally stopped in front of Amiens, this sector had an interval of comparative quiet, except for frequent small raids by the Australians holding it, while the struggle developed on other parts of the front.

Towards the end of June, the 4th Army commander, Gen. Rawlinson, decided that an operation on rather a larger scale than the Australians had so far carried out had every chance of meeting with success. On July 4, six Australian battalions, working in close co-operation with some 60 tanks, together with four companies of the American 33rd division, which was attached to the 4th Army for training, attacked on a front of nearly three and a-half miles, and with consummate ease and only small losses captured the ridge running from Villers-Bretonneux down to the Somme at Hamel. This operation gave greater depth and valuable positions for observation to the British line, while at the same time it denied to the enemy important observation over much of the Somme valley. It also showed that the German infantry was no longer

the determined foe that it had been in 1916 and 1917, and that the enemy's defences were not formidable. The real significance of the operation was its evidence that on the 4th Army front a well organized attack, supported by tanks well trained beforehand to co-operate with infantry, would have every prospect of breaking through the enemy's defences, given the element of surprise.

On July 17 Rawlinson submitted proposals to Haig for an attack by the 4th Army on a front of approximately 16m. from Moreuil to Morlancourt. The plan was at once approved by Haig, who, in response to a request from Gen. Foch that the British should take the offensive on the Lys front with a view to recovering the important position on Kemmel hill, recommended that the venue for the British offensive should be changed to the Amiens front. To this proposal Foch assented with the modification that the French 1st Army (Debeney) should attack on the southern portion of the front between Moreuil and the River Luce (about three and a half miles) shoulder to shoulder with the British 4th Army, both armies operating under the direct orders of the British commander-in-chief.

On July 28 Foch issued his orders. "The object of the operation," he said, "is to disengage Amiens and the Amiens-Paris railway, as well as to beat and push back the enemy between the Somme and the Avre. The offensive, covered on the north by the Somme, is to push forward as far as possible in the direction of Roye." The Amiens-Roye road was fixed as the dividing line between French and British, and Aug. 10 was to be the day of attack. This date was subsequently advanced to Aug. 8.

Preparations for Surprise Attack.—On July 26 orders were received that the preparations, which Rawlinson had already begun in anticipation of sanction being given to his proposed operation, were to be pressed forward with all speed. The essence of the whole plan was secrecy. Unless the existing conditions both as regards the state of the hostile defences and the absence of reserves could be maintained success could not be guaranteed, and in consequence it was not until July 31 that divisional commanders even were told the true story of the operations, a false but adequate reason having been given for the preparations.

On Aug. 1 the strength of the 4th Army was seven divisions, one cavalry division, three tank battalions (about 110 tanks), 11 squadrons R.A.F. and 1,000 guns and howitzers. By zero hour on Aug. 8, this force had been increased to 13 divisions, three cavalry divisions, 12 tank battalions (about 456 tanks), 17 squadrons R.A.F., and over 2,000 guns and howitzers, of which 672 were "heavies." In addition, one division, retained in the hands of the commander-in-chief, was brought into the area, while two others arrived on the day of the battle. The cavalry, about 96 whippet tanks, and part of the artillery were moved by road, the remainder being brought up in some 290 special trains, 230 for personnel and guns and 60 for ammunition and *matériel*.

As the Canadian Corps, at the time in reserve near Arras, had not been involved in the desperate fighting earlier in the year, it was realized that wherever it was identified in the line by the enemy an early offensive would certainly be expected. The first problem, therefore, was to camouflage its move and to keep its presence secret up to the last possible moment. With this object a few Canadian units were moved into the line near Kemmel, whilst the remainder moved down to the Amiens front, though it was not allowed to take over its part of the front line until just before zero hour on Aug. 8. The task also of introducing and registering a very large number of guns without detection was no easy matter. All movements of artillery units and the formation of ammunition dumps had to be done at night. A strictly limited number of guns only were allowed to fire daily, nothing above the normal number of rounds being permitted.

General Plan of Attack.—The British front of attack was divided between the Canadian Corps (Currie, four divisions) from the Amiens-Roye road to the Amiens-Chaulnes railway, 7,500yds.; the Australian Corps (Monash, five divisions) thence to the Somme, 7,500yds.; and the 3rd Corps (Butler, four divisions) thence to the River Ancre, 5,000yds.; while to each corps a proportion of tanks was allotted. The task of the 3rd Corps was to form a defensive flank north of the Somme, whilst the French 1st

Army would carry out a similar task on the right of the Canadians. Three successive objectives were assigned at distances respectively of two to two and a-half, three to five, and six to eight miles from the original starting line. With the ample provision of tanks it was possible to repeat and improve upon the Cambrai experiment (*see* CAMBRAI, BATTLE OF) of Nov. 1917, and thus to gain the full value of surprise; a preliminary bombardment was omitted, the artillery, infantry and tank action commencing simultaneously at zero hour, up to which moment there was no divergence from the ordinary daily routine of trench warfare. With the French, however, the situation was different, as tanks were not available to assist them, and Debeney decided to bombard the enemy's defences for 40 minutes prior to the infantry advance. The zero hour, 4.20 A.M., of the 4th Army advance synchronised with the opening of the French bombardment.

The hostile forces believed to be available to oppose the British were six divisions in first line with eight in reserve of the German 2nd Army (Marwitz), while in front of the attacking corps of the French 1st Army were the two left divisions of the German 2nd Army and one division of the German 18th Army (Hutier). By the morning of Aug. 8 all preparations for the battle were complete, and the Allied forces, all unsuspected by the enemy, were about to enter upon the first stage of their march to the Rhine.

The British Attack, Aug. 8.—At 4.20 A.M. (approximately one hour before sunrise) Rawlinson's 4th Army, under cover of a powerful barrage, debouched to the assault. Thick ground mist veiled the advance from the eyes of the Germans, who were completely surprised and overwhelmed with little resistance along nearly the whole front. The Canadian Corps attacked with three divisions in line, the 3rd, 1st and 2nd in order from the right. The Canadian 3rd Division, making light of the difficult task of debouching from a narrow bridgehead on the south bank of the River Luce, captured Hangard and Demuin, and by noon had carried its front forward to the second objective, between Mézières and Cayeux. The 3rd Cavalry Division then went through, followed by the Canadian 4th Division, but, after taking Beaucourt, was held up by machine-gun fire. The infantry on coming up succeeded in pushing forward, though they were unable that day to capture Le Quesnel, the final objective.

The Canadian 1st Division in the centre reached the first objective by 6.20 A.M.; but the Canadian 2nd Division on its left only attained it an hour and a half later, having met with strong opposition at Marcelcave. At 8.20 A.M. the advance was resumed, the German machine-gunners putting up considerable resistance against the Canadian 2nd Division. The 1st Cavalry Division now sent forward two brigades, one of which passed through the Canadian 2nd Division and drove far into hostile territory, attaining the final objective in conjunction with the infantry, which followed up, clearing the ground in rear of the cavalry. By the end of the day's fighting the Canadian Corps had, with the exception already noted on the extreme right, carried out its appointed task, and captured over 5,000 prisoners and 161 guns.

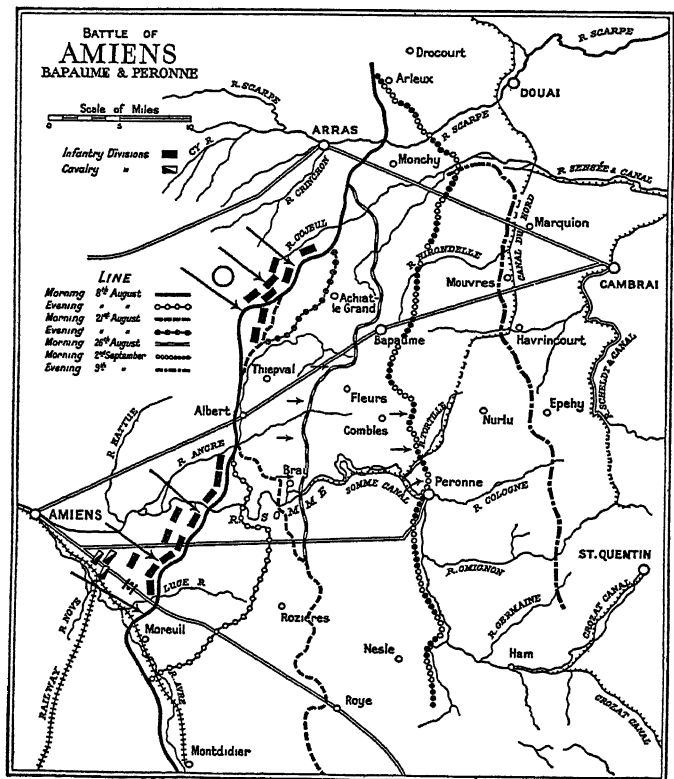

Progress in the Centre.—The Australian Corps in the centre of the British attack had their 2nd and 3rd Divisions in the front line with the 5th and 4th in support, the 1st Division being in reserve. The leading line, aided most effectively by the tanks, reached the first objective with little opposition. The 5th and 4th Divisions then continued the advance, pushing on beyond Bayonvillers and Morcourt, and occupied the second objective by about 10.30 A.M., when a brigade of the 1st Cavalry Division passed through towards Harbonnières and armoured cars raced forward down the Brie road, penetrating far into the enemy's back areas. Behind them, the Australians, throwing back their left to face the enemy on the north bank of the Somme, pushed forward their centre and right to the final objective just west of Vauvillers and Proyart, where they found the cavalry held up. During the day the Australians took nearly 8,000 prisoners and 173 guns.

North of the Somme the 3rd Corps had not met with the same measure of success. The plan had been disarranged by a local German attack near Morlancourt on Aug. 6, which forced back a

part of the Allied line some 800 yards. In addition the terrain was not so suitable for tank manoeuvres as south of the river. The attack opened with the 58th, 18th and 12th Divisions from right to left. After the first objective had been gained, the further advance broke down against the resistance of the enemy holding the Chipilly spur, while further north the enemy counter-attacked and drove back the advanced attacking troops. Nevertheless the 3rd Corps captured during the day nearly 2,400 prisoners and 40 guns.

The results of this most successful day's battle were the complete defeat and rout of 11 German divisions, a gain of ground to an average depth of six to seven miles on a front of eight miles, the capture of over 16,000 prisoners, 373 guns, several thousand machine-guns and quantities of ammunition and stores. Most important of all, the battle destroyed the last hope of German victory. "It was," says Ludendorff, "the black day of the German army in the war . . . To continue would be a gamble. The war would have to be ended."

The French Attack, Aug. 8.—At 4.20 A.M., simultaneous with the British assault, the French bombardment of the enemy's position on the commanding ground in the angle between the rivers Avre and Luce opened, and at 5.05 A.M. the French infantry in this sector debouched to the attack. For this operation Debeney allotted three divisions of the 31st Corps, of which one division was given the task of capturing Moreuil. Despite a stubborn defence, the enemy was gradually driven back and Moreuil wood

THE BATTLE OF AMIENS IN THE WORLD WAR, AUG.—SEPT. 1918
The successive stages of the great British advance initiated by the battle of Amiens, Aug. 8, 1918, brought the British to the outworks of the Hindenburg Line which they then attacked, breaking through at the end of September. The morale of the German Army was broken, and the way paved for the final victory three months later

taken. This feature was of great importance, as its capture secured the flank of the British advance. At 8.20 A.M. the next corps to the south, the 9th Corps, crossed the Avre, south of Moreuil, and extended the front of attack, which by the end of the day's fighting reached the general line Plessier-Fresnoy (excl.). Although the French attack did not quite reach its final objective for the day, its main task of securing the British flank was carried out, while some 3,000 prisoners and many guns were captured. The other two corps of the French 1st Army did not take an offensive rôle until next day. The result also enabled Gen. Fayolle, com-

manding the French reserve group of armies, to carry out his plan of extending the battle front farther to the south on Aug. 9.

Continuation of British Advance, Aug. 9-11.—It was decided by Rawlinson that the 4th Army should on Aug. 9 continue its advance to the line Roye-Chaulnes-Bray-Dernancourt. The main attack was entrusted to the Canadian Corps, which was to push south-east to the line Roye-Hallu, whilst the Australian corps was to secure its left between the latter place and Méricourt, and the 3rd Corps to advance to Etinehem and form a defensive flank north of the Somme.

Early in the morning the Canadians captured the village of Le Quesnel, thus completing the capture of all the objectives allotted to the main British attack for the 8th. During the day, assisted by cavalry, they advanced the line an average of five miles and halted for the night on a general line east of Rouvroy and Méharicourt. To the north the Australians reached Lihons hill and captured Framerville after stubborn fighting. The 3rd Corps, north of the Somme, cleared the Chipilly spur and occupied Morlancourt. During the day six German divisions reinforced the front from neighbouring armies. On Aug. 10 and 11 the advance continued against ever-stiffening resistance and hostile counter-attacks, eventually reaching the general line Le Quesnoy-Lihons-Raincourt, whilst north of the river the Etinehem spur was completely cleared.

It was now clear that to push the offensive farther would lead to disproportionate loss with little corresponding gain. The enemy had reformed his front, shattered on the 8th, by fresh troops from other portions of the line, and had settled down on the edge of the area devastated in the Somme battles of 1916, where a maze of old trenches, wire and shell holes rendered defence easy and rapid advance impracticable. Rawlinson had engaged all his 13 divisions, units were tired and in need of a breathing-space. He therefore decided to allow his troops a few days' rest while preparing for a renewal of the attack on Aug. 15. Units in the line were relieved and tired infantry and cavalry withdrawn into reserve.

French Operations, Aug. 9-11.—On Aug. 9 Debeney made an encircling attack, south-east and north-east with his 10th and 35th Corps, his objective being Montdidier. The former was checked, and thus the garrison of the town managed to slip out, but the town was occupied and the rearguard captured on the morning of Aug. 10. In the meantime the 31st Corps to the north reached the line Pierrepont-Arvillers. By the night of the 11th it gained the western outskirts of Roye. On Aug. 10 Fayolle brought in the French 3rd Army (Humbert) on the right. Attacking on the front Courcelles-Gournay in the direction of Lassigny, it made an advance of an average depth of three to four miles. Next day the front was extended still farther southwards, but, owing to the enemy's resistance becoming stronger, progress was thenceforward slow.

British Operations, Aug. 12-21.—Owing to the difficulty of reorganizing the front of attack and of bringing up the guns, the attack arranged for Aug. 15 did not materialize, and up to the 21st only local actions took place on the 4th Army front. British attacks alternated with hostile counter-attacks, the line after hard fighting reaching Damery-Lihons-Proyart-Dernancourt. On Aug. 17 Haig decided to transfer temporarily the centre of gravity of the British offensive to the 3rd and 1st Army areas. The Canadian Corps was taken out of the line and the French 1st Army took over the British front as far north as Lihons. During the period Aug. 8-21 the 4th Army had forced back the Germans to a depth of 12m., had defeated or engaged with its own 13 divisions no less than 27 of the enemy's, had taken over 23,000 prisoners and 400 guns and had killed and wounded more than an equivalent number, at a cost to itself of some 27,000 casualties.

French Operations, Aug. 12-21.—During this period the French 1st Army, which remained under Haig's command until the 16th, also came to a halt, but the French 3rd Army, whose advance was assisted by the French 10th Army's attack east of the Oise, after a hard and determined defence succeeded in occupying Lassigny on Aug. 21. In the 12 days' fighting Humbert's army of seven divisions had driven eight hostile divisions from their strong vantage-ground and had taken 5,000 prisoners and 100 guns.

General Results of the Battle.—The course and results of the fortnight's fighting may be summed up as follows: The three Allied armies (British 4th, French 1st and 3rd), with 32 divisions, had attacked and defeated the German 2nd and 18th Armies of 42 divisions. The Allies had advanced to a depth of 6-13m. on a front of 47m. taking 40,000 prisoners and 600 guns. Most important of all, the Allied lateral communications between Paris and the north had been cleared, and a wide breach had been made in the German front, susceptible, as events were to show, of being rapidly widened to either flank by further Allied attacks. A shattering blow had been dealt to the *morale* of the German Army and their high command, from the effects of which neither was destined to recover. The battle of Amiens was the first page in the story of the Allied victory of 1918.

THE BATTLE OF BAPAUME-PÉRONNE

This operation is dealt with here as it formed the immediate sequel to the battle of Amiens, in the scheme of the British offensive leading up to the assault of the Hindenburg Line. At the time the front of Byng's 3rd Army, which was the northern neighbour of Rawlinson's Army, was held as follows: 5th Corps (Shute, with three divisions) from the left of the 4th Army just north of Albert to Beaucourt, 4th Corps (Harper, with five divisions) thence as far as opposite Ablainzeville, 6th Corps (Haldane, with four divisions) thence to the army boundary south of Arras. Preparations were at once put in hand, the operations being timed to begin on Aug. 21, by which date the rapid advance of the 4th Army had been checked on the western edge of the old Somme battlefields of 1916.

Attack by 3rd Army.—On Aug. 21 a preliminary operation was carried out by the 4th and 6th Corps together with the left division of the 5th Corps, in order to get within striking distance of the enemy's main defensive position along the Arras-Albert railway. This attack, which was entirely successful and resulted in the capture of some 2,000 prisoners, enabled Byng to spend the 22nd in bringing up his guns preparatory to the main attack on the 23rd, on which date a general advance on the whole army front, together with that portion of the 4th Army which was north of the Somme, was timed to take place.

On the 23rd Byng attacked on a front of 16m. from just north of Albert to the Cojeul. Though stubborn resistance was encountered considerable progress was made, the objective being reached all along the line. The 4th Corps, in the centre, pushed forward to Bihucourt and Loupart wood, while the 6th Corps captured Ervillers and established itself east of the Arras-Bapaume road in the vicinity of Boyelles. On the right the 5th Corps, in conjunction with the 3rd Corps (4th Army), pushed out its right and established itself on the hills overlooking the town of Albert just west of La Boisselle. During the day 5,000 prisoners and a number of guns were taken.

The advance was continued on the 24th and 25th, by the evening of which the 4th Corps had pushed forward as far as the line Favreuil-Mory, thus threatening the enemy's line of retreat from Bapaume. To the south the 5th Corps, after capturing the Thiepval stronghold on the 24th, attained a general line west of Contalmaison and Courcellette. On the left the 6th Corps occupied St. Léger and Henin-sur-Cojeul but was held up in front of Croisilles.

Fourth Army Operations.—The operations of the 3rd Army were closely supported by the 4th Army troops north of the Somme. On the 22nd the 3rd Corps and left Australian Division attacked on a front of 7,000yd., reaching all their objectives to a depth of from 2,000 to 3,000 yards. In the afternoon a strong counter-attack developed against the 3rd Corps right division, and much of the ground won earlier in the day was lost. During the next three days the advanced continued in conjunction with the 3rd Army, and on the evening of the 25th the front had reached a general line along the high ground west of Suzanne-Mametz. South of the Somme the Australian Corps on the 23rd advanced up to the edge of the old Somme battlefield, capturing 3,000 prisoners and 23 guns. As a result of the critical situation caused by these operations, the German Higher Command ordered

Von Boehm, commanding the group of armies between the Ancre and the Aisne, to fall back to the general line Quéant-east of Bapaume-Péronne-Ham. This movement was carried out on the 26th and 27th.

On the 26th the 5th Corps made a rapid advance, whilst the 4th Corps continued to swing round to the north-east of Bapaume, occupying Beugnâtre. On the evening of the 25th, the 17th Corps (Ferguson) relieved the 6th and undertook the difficult task of dispossessing the enemy of his strong position in the vicinity of Croisilles. During the next week a stubborn defence was shown all along the front, which by the evening of Sept. 2 had reached the enemy's position on the line Morval-Haplincourt-Noreuil. During the 13 days' fighting the 14 divisions of the 3rd Army had engaged 23 hostile divisions, had taken from them 11,000 prisoners and many guns and had driven them back a depth of 8-13m. on a front of 20m., besides inflicting heavy losses in killed and wounded.

On the 4th Army front north of the Somme, the 3rd Corps, together with the 3rd Australian Division, continued the advance in touch with the 3rd Army. South of the Somme the advance had been rapid, and on the evening of the 29th the river had been reached between Cizaucourt and Biaches, whence the line continued northwards to Combles. In view of the small prospect of success afforded by an attempt to force the strongly-held river line south of Péronne, Rawlinson decided that the next operation must be a strong advance by the centre and left towards Nurlu in order to turn the river line. Before that could be done, however, the key to it, the dominating height of Mont St. Quentin, which commanded all the country to the north and west, including all the river passages by which it could be approached, had to be captured.

Capture of Mont St. Quentin.—Although the operations which resulted in its capture by the Australians extended over only a few miles of front, they were of such importance to the general advance and so brilliantly executed that a description will be given in rather greater detail. On the 30th a bridge-head on the north bank of the river near Cléry was seized, and by 4 A.M. on the 31st the 5th Brigade (2nd Australian Division) had crossed over and by 7 A.M. had captured Mont St. Quentin village, the right being held up in front of Anvil wood. Shortly afterwards a strong counter-attack developed and drove the British line back to the road on the south-west side of the village. As a result of the day's fighting the 5th Brigade of some 1,200 rifles had penetrated to a depth of 2,000yd., and, though reduced to only 600 rifles, had held out on a wide front of 4,000yd. against repeated and desperate counter-blow.

Next morning the 6th Brigade, which had crossed the river the evening before, passed through the 5th Brigade, and after a short bombardment stormed the village and wood and established itself on the height. Meanwhile the 14th Brigade (5th Australian Division) also passed through south of the 6th Brigade, and, brushing aside all opposition, entered and occupied Péronne, only a small portion of the suburbs on the north-east remaining in the enemy's hands. Next day the Australians occupied Allaines, and the 3rd Corps St. Pierre Vaast and Vaux woods. The line of the Somme had been turned, due, as a detailed account would show, to the brilliant initiative of every commander, from the army commander to the section leader, and to the magnificent fighting qualities of the Australian soldier. Between Aug. 22 and Sept. 2 the 4th Army of nine divisions had engaged 23 of the enemy's divisions and taken 23,000 prisoners and many guns.

Results of the Battle.—Byng's and Rawlinson's armies totaling together 23 divisions had defeated 46 German divisions. On a front of 28m. they had advanced to a depth of six to 13m., capturing 34,250 prisoners and 270 guns. The whole area of the Somme battlefields, which had cost the British five months of bitter fighting in 1916, had been reconquered in less than a fortnight; more than half the ground gained by the German spring advance had been recovered, the only good natural line of defence west of the Hindenburg system had been broken, and the shifting of the moral and material balance in favour of the British and against the Germans was not only heartening to the troops of the Allies but had become patent to the world.

AMIL MARDUK or EVIL MERODACH: see MARDUK.

AMINES, in chemistry, derivatives of ammonia (*q.v.*) in which one or more of the three hydrogen atoms are replaced by alkyl or aryl groups. The replacement of one hydrogen atom by one alkyl or aryl group gives rise to primary amines; of two hydrogen atoms by two groups to secondary amines; of three hydrogen atoms by three groups to tertiary amines. The tertiary amines possess the power of combining with one molecular proportion of an alkyl iodide to form quaternary ammonium salts. The structural relations of these compounds may be shown thus:

Aliphatic Amines.—These compounds possess properties very similar to those of ammonia, the lowest members of the series being combustible gases readily soluble in water. The next higher members of the series are liquids of low boiling point also readily soluble in water, the solubility and volatility, however, decreasing with the increasing carbon content of the molecule until the highest members of the series are odourless solids of high boiling point and are insoluble in water. They are all strong bases, readily forming salts with the mineral acids, and double salts with the chlorides of gold, platinum and mercury. They are ionized in aqueous solution to a much greater extent than ammonia, the quaternary ammonium bases being the most ionized.

Many methods have been devised for the preparation of primary amines, methylamine having been isolated in 1849 by A. Wurtz on boiling methyl isocyanate with caustic potash, $\text{CON}\cdot\text{CH}_3 + 2\text{KHO} = \text{CH}_3\text{NH}_2 + \text{K}_2\text{CO}_3$. The other methods are:—the reduction of nitriles with alcohol and sodium (A. Ladenburg, 1886); heating the esters of nitric acid with alcoholic ammonia at 100° C (O. Wallach, 1881); the action of reducing agents on nitro-paraffins; the action of zinc and hydrochloric acid on aldehyde-ammonias; the reduction of phenylhydrazones and oximes of aldehydes and ketones with sodium amalgam in the presence of alcohol and sodium acetate (J. Tafel, and H. Goldschmidt, 1886) the acidic hydrolysis of the isonitriles, $\text{R}\cdot\text{NC} + 2\text{H}_2\text{O} = \text{R}\cdot\text{HN}_2 + \text{H}_2\text{CO}_2$, heating the mustard oils with a mineral acid; the hydrolysis of the alkyl phthalimides (S. Gabriel, 1887); distillation of the amino-acids with baryta; the action of bromine and caustic potash on the acid-amides (A. W. Hofmann, 1885); and the hydrolysis of substituted urethanes (Th. Curtius, 1894).

The secondary amines are prepared, together with the primary and tertiary, by the action of ammonia on the alkyl iodides (see below), or by the hydrolysis of para-nitroso derivatives of tertiary aromatic amines, such as para-nitrosodimethylaniline, thus:

By the action of ammonia on the alkyl iodides a complex mixture of primary, secondary and tertiary amines, along with a quaternary ammonium salt, is obtained, the separation of which is difficult. The method worked out by A. W. Hofmann in 1850 for the ethylamines is as follows:—the mixture is distilled with caustic potash, when the primary, secondary and tertiary amines distil over, and the quaternary ammonium salt remains behind unaffected. The aqueous solution of the amines is now shaken with

diethyl oxalate, when the primary amine forms a crystalline dialkylloxamate and the secondary amine an insoluble liquid, which is an ethyl dialkylloxamate, the tertiary amine not reacting: $(\text{CO}_2\text{C}_2\text{H}_5)_2 + 2\text{NHR} = (\text{CO}\cdot\text{NHR})_2 + 2\text{C}_2\text{H}_5\text{OH}$; $(\text{CO}_2\text{C}_2\text{H}_5)_2 + \text{NHR}_2 = \text{C}_2\text{H}_5\text{O}_2\text{C}\cdot\text{CONR}_2 + \text{C}_2\text{H}_5\text{OH}$. The tertiary amine is then distilled off, the residual products separated by filtration and finally hydrolysed by a caustic alkali.

A more general method due to O. Hinsberg (1890) consists in treating the mixed bases with benzene sulphonic chloride (or *p*-toluene sulphonic chloride). The primary base gives an acidic derivative, $\text{C}_6\text{H}_5\cdot\text{SO}_2\cdot\text{NHR}$ soluble in aqueous alkali, the secondary base furnishes the compound, $\text{C}_6\text{H}_5\cdot\text{SO}_2\cdot\text{NR}_2$, insoluble in alkali, whereas the tertiary base does not react, the process is applicable to both aliphatic and aromatic amines.

The primary, secondary and tertiary amines may be readily distinguished by their behaviour with various reagents. Primary amines when heated with alcoholic potash and chloroform yield isonitriles, which are readily detected by their offensive smell. The secondary and tertiary amines do not give this reaction. With nitrous acid, the primary amines yield alcohols, the secondary amines yield nitrosamines and the tertiary amines do not react: $\text{R}\cdot\text{NH}_2 + \text{ONOH} = \text{R}\cdot\text{OH} + \text{N}_2 + \text{H}_2\text{O}$; $\text{R}_2\text{NH} + \text{ONOH} = \text{R}_2\text{N}\cdot\text{NO} + \text{H}_2\text{O}$. The condensation with benzene sulphonic chloride in the presence of alkali also furnishes a method of diagnosis (*see above*). Primary amines heated with carbon disulphide in alcoholic solution are converted into mustard oils, when the dithiocarbamate first produced is heated with a solution of mercuric chloride. Primary and secondary amines condense with *o*-xylylene dibromide giving two and one molecular proportions of hydrogen bromide, respectively. Tertiary aliphatic amines form additive compounds with this reagent (Scholtz 1898).

Methylamine, CH_3NH_2 , occurring in *Mercurialis perennis*, in bone-oil and herring brine, is also a decomposition product of many alkaloids. At ordinary temperatures it is a gas with a strong ammoniacal smell, burns readily and is exceedingly soluble in water. Dimethylamine $(\text{CH}_3)_2\text{NH}$, found in Peruvian guano, is a heavy vapour which liquefies at 7°C and has a strong fish-like smell. Trimethylamine $(\text{CH}_3)_3\text{N}$, is a vapour very similar to dimethylamine, but liquefies at $3.2\text{--}3.8^\circ\text{C}$. It is usually obtained from "vinasses," the residue obtained from the distillation of beet sugar alcohol. The three methylamines can be obtained from ammonia and form aldehyde solution and a suitable separation for each of the three has been devised by E. Werner (1917). Tetramethylammonium iodide, $\text{N}(\text{CH}_3)_4\text{I}$, the chief product obtained by the action of methyl iodide on ammonia (Hofmann), crystallizes in quadratic prisms and has a bitter taste. By warming its aqueous solution with an excess of silver oxide, it is converted into tetramethylammonium hydroxide $\text{N}(\text{CH}_3)_4\text{OH}$, which crystallizes in hygroscopic needles, and has a very alkaline reaction. This hydroxide forms many crystalline salts, absorbs carbon dioxide and precipitates many metallic hydroxides. On dry distillation it is decomposed into trimethylamine and methyl alcohol. If the nitrogen atom in a quaternary ammonium salt is in combination with four different groups, then the molecule is asymmetric, and the salt can be resolved into optically active enantiomorphous isomerides (W. J. Pope, 1901 [*see STEREO-CHEMISTRY*]).

Diamines.—The diamines contain two amino-groups and are of importance because two of them are identical with the ptomaines produced by the putrefactive action of bacteria on albumen and other related substances. Ethylenediamine, $\text{C}_2\text{H}_4(\text{NH}_2)_2$, may be prepared by heating ethylene dibromide with alcoholic ammonia to 100°C (F. S. Cloez, 1853); or by the action of tin and hydrochloric acid on cyanogen (T. Fairley, 1864). It is an alkaline liquid, which when anhydrous boils at 116.5°C . Nitrous acid converts it into ethylene oxide. It combines directly with many metallic salts. (S. F. Jørgensen, 1889.) Trimethylenediamine, $\text{NH}_2(\text{CH}_2)_3\text{NH}_2$, prepared by the action of ammonia on trimethylene bromide (E. Fischer, 1884) is a liquid which boils at $135\text{--}136^\circ\text{C}$. Tetramethylenediamine (putrescine), $\text{NH}_2(\text{CH}_2)_4\text{NH}_2$, is prepared by reducing ethylene dicyanide (succinonitrile) with sodium in absolute alcoholic solution (A. Ladenburg, 1886).

It melts at 27°C and is easily soluble in water. Pentamethylenediamine (cadaverine), $\text{NH}_2(\text{CH}_2)_5\text{NH}_2$, is prepared by reducing trimethylene cyanide in ether solution by zinc and hydrochloric acid (A. Ladenburg, 1883). Cadaverine is a syrup at ordinary temperatures and boils at $178\text{--}179^\circ\text{C}$. It is readily soluble in water and alcohol, but only slightly soluble in ether.

Aromatic Amines.—The aromatic amines in some respects resemble the aliphatic amines, since they form salts with acids, and double salts with platinum chloride, and also distil without decomposition. On the other hand, they are much weaker bases than the aliphatic amines, their salts undergoing hydrolytic dissociation in aqueous solution. The primary aromatic amines may be prepared by the reduction of the nitro-hydrocarbons, the reducing agents used being either alcoholic ammonium sulphide (N. Zinin), zinc and hydrochloric acid (A. W. Hofmann), an alcoholic solution of stannous chloride containing hydrochloric acid (R. Anschütz, 1886), tin and hydrochloric acid, or on the manufacturing scale iron and water acidified by hydrochloric acid. They may also be obtained by the reduction of nitroso compounds and of azo- and hydrazo-compounds and of hydrazones, by distilling the amino-acids with lime, by heating phenols with ammonio-zinc chloride (V. Merz, 1880), and by heating the secondary and tertiary bases with concentrated hydrochloric acid to about 180°C . At about $300\text{--}400^\circ\text{C}$ the alkyl chloride formed in this reaction attacks the benzene nucleus and replaces hydrogen by an alkyl group or groups, forming primary amines homologous with the original amine; thus methylaniline hydrochloride is converted into para- and ortho-toluidine hydrochloride, and phenyltrimethylammonium iodide is converted into mesidine hydriodide.

The primary aromatic amines are colourless liquids or crystalline solids which are sparingly soluble in water, but readily soluble in the common organic solvents. When heated with alkyl or aryl iodides they are converted into secondary and tertiary amines. When heated with concentrated sulphuric acid they become sulphonated. They form condensation products with aldehydes, benzaldehyde and aniline giving rise to benzylideneaniline, $\text{C}_6\text{H}_5\text{N}:\text{CH}\cdot\text{C}_6\text{H}_5$, and when heated with organic acids forming anilides. They give the isonitrile reaction (*see above*) when warmed with chloroform and a caustic alkali, and form alkyl thioureas when heated with an alcoholic solution of carbon bisulphide. When warmed with a solution of nitrous acid, they are converted into phenols; if, however, nitrous acid be added to an ice-cold solution of a primary amine in excess of mineral acid, a diazonium salt is formed (*see ANILINE, AZO-COMPOUNDS AND DIAZO-COMPOUNDS*).

The secondary amines may be of two types—namely, the purely aromatic amines, and the mixed secondary amines, which contain an aromatic residue and an alkyl group. The purely aromatic amines are obtained by heating the primary amines with their hydrochlorides, and, in some cases, by heating a phenol with a primary aromatic amine and a catalyst (anhydrous zinc chloride or 1% of iodine). The mixed secondary amines are prepared by the action of alkyl iodides on the primary amines, or by heating salts of the primary amine with alcohols under pressure. (*See ANILINE.*) The mixed secondary amines have basic properties, but the purely aromatic secondary amines are only very feeble bases. Both classes readily exchange the imide hydrogen for acid radicals and give nitrosamines with nitrous acid.

The tertiary amines may also be of two types, the purely aromatic and the mixed type. The mixed tertiary amines are produced by the action of alkyl halides on the primary amines. The simplest aromatic tertiary amine, triphenylamine, is prepared by the action of brombenzene on sodium diphenylamine (C. Heydrich, 1885).

Benzylamine, $\text{C}_6\text{H}_5\cdot\text{CH}_2\cdot\text{NH}_2$, may be prepared by reducing benzonitrile in alcoholic solution with zinc and acetic acid (O. Mendius, 1862), or by metallic sodium (E. Bamberger, 1887). It can also be obtained together with di- and tri-benzylamines by the action of ammonia on benzyl chloride (S. Cannizzaro, 1865). It is a liquid which boils at 183°C , has a strongly alkaline reaction, and is miscible in all proportions with water, alcohol and ether. Diphenylamine, $(\text{C}_6\text{H}_5)_2\text{NH}$, the simplest representative of the true aromatic secondary amines is prepared by heating aniline and

aniline hydrochloride for some hours to 210–240° C (Ch. Girard and G. de Laire, 1866). It crystallizes in white plates, which melt at 45° C and boil at 302° C.

Aromatic Diamines.—The simplest aromatic diamines are prepared by reducing the three nitranilines. Ortho-phenylenediamine, $C_6H_4(NH_2)_2$, crystallizes from water in plates, which melt at 102–103° C and boil at 256–258° C. The ortho-diamines are characterized by the large number of condensation products they form (see IMINAZOLES, QUINOXALINES, etc.). Meta-phenylenediamine crystallizes in rhombic plates which melt at 63° C and boil at 287° C. It is easily soluble in water and alcohol. Para-phenylenediamine may be prepared as above, and also by the reduction of aminoazobenzene. It crystallizes in tables which melt at 140° C and boil at 267° C. When heated with 10% hydrochloric acid to 180° C the three diamines yield the corresponding dihydroxybenzenes (J. Meyer, 1897). The three classes of aromatic diamines may be distinguished by their behaviour towards nitrous acid. The ortho-compounds condense to azimino benzenes, the meta-compounds yield azo-dyestuffs and the para-compounds yield bis-diazo compounds of the type $XN_2 \cdot C_6H_4 \cdot N_2X$. (See DIAZO-COMPOUNDS.)

REFERENCE.—T. E. Thorpe, *Dictionary of Applied Chemistry* (1921). "Amines," p. 185. (G. T. M.)

AMINOSIS, the abnormal presence of amino-acids in the organism. Proteins are made up of long chains of amino-acids. In the process of metabolism the proteins are split up into their constituent amino-acids. Some of these acids are used in the synthesis of new body proteins, but the majority are further reduced by oxidation and deamination, to carbon dioxide and water. The amine radical (NH_2) is synthesized into urea and excreted as such. In certain abnormalities of metabolism, this change does not take place and the body loses the power of converting the amino-acids into their normal end products. In these circumstances we find amino-acids in the urine. There are several types in this group. The most important form is when homogenistic acid is found in the urine. This substance, in the presence of oxygen and alkali, gives the urine a dark brown colour.

AMIOT, JEAN JOSEPH MARIE (1718–1793), French Jesuit missionary, was born at Toulon in Feb. 1718. He entered the Society of Jesus in 1737 and was sent in 1750 as a missionary to China. He soon won the confidence of the Emperor Kien-lung, and spent the remainder of his life at Peking, where he died Oct. 9 1793. Amiot provided a key to the thought and life of the Far East, by his *Dictionnaire tartare-manichou-français* (Paris, 1789). His other writings are to be found chiefly in the *Mémoires concernant l'histoire, les sciences et les arts de Chinois* (Paris, 1776–91). The *Vie de Confucius*, the 12th vol. of that collection, is complete and accurate.

BIBLIOGRAPHY.—For full bibliography see De Backer and C. Sommervogel, *Bibliothèque de la Cie. de Jésus*, i. 294–303; for his works on Chinese music see F. J. Fétis, *Biog. univers. des musiciens* (Brussels, 1837–44).

AMIR or AMEER, a title common in the Mohammedan east (from an Arabic word meaning "commander," from the root *amr*, "commanding"). The form *emir* is also employed in English. The word originally signified a naval or military commander, but very early came to be applied to any high office-bearer, lord or chief. The caliph had the style of *Amir ul Omara*, "lord of lords." *Amir ul Muminim*, or "commander of the faithful," the title of the sultans of Turkey, was first assumed by Abu Bekr, and was taken by most of the various dynasties which claimed the caliphate.

The use of the word is akin to that of the English "lord," sometimes connoting office, as in *Amir ulahghal* (minister of finance) under the Almohades (cf. "lord of the treasury"), sometimes mere dignity, as in the case of the title of honour borne by all descendants of the Prophet. Sometimes it connotes the meaning of "sovereign lord," in which sense it was assumed by the rulers of Afghanistan and Bukhara, the title implying a lesser dignity than that of sultan. The word (confused not unnaturally with the particle usually attached to it) is the origin of the English "admiral."

AMIR 'ALI, SEYYID (1849–1928), Indian jurist and Muslim leader, was born April 6, 1849, of an Arab family, tracing descent from the Prophet, which migrated from Persia and settled at Mohan in Oudh in the middle of the 18th century. At Hugli college, Calcutta, he graduated in 1867. He came to London and was called to the bar of the Inner Temple in 1873. He had already published *A Critical Examination of the Life and Teachings of Mahomed*, the first of a series of books of Islamic modernist interpretation and apologetics, which have given him a recognized place in English literature. He was for some years a lecturer on Mohammedan law at the Presidency College, Calcutta, and afterwards President of the faculty of law at the university there. He was also chief presidency magistrate of Calcutta and in 1890 was appointed a judge of the Bengal High Court, being the first Mohammedan to reach the bench in India. He was made a C.I.E. in 1887. In 1904 he retired and settled in England. He was the first Indian to be sworn (Nov. 1909) of the Privy Council and to serve on its judicial committee. But his chief ambition in life was the advancement of the Indian Muslims, both morally and materially, along practical and constitutional lines and his activities paved the way for the Morley-Minto and subsequent reforms. He died at his home at Rudgwick, Sussex, on Aug. 3, 1928.

AMIS ET AMILES, the title of an old French romance. In its earlier and simpler form it is the story of two friends, one of whom, Amis, was smitten with leprosy because he had committed perjury to save his friend. A vision informed him that he could only be cured by bathing in the blood of Amiles' children. When Amiles learnt this he killed the children, who were, however, miraculously restored to life after the cure of Amis. The tale was probably of Oriental origin, and was eventually attached to the Carolingian cycle as a 12th-century *chanson de geste*, written in decasyllabic assonanced verse, each stanza being terminated by a short line. Amis has married Lubias and become count of Blaives (Blaye), while Amiles has become seneschal at the court of Charlemagne, and is seduced by the emperor's daughter, Bellisant. The lovers are betrayed, and Amiles, fearing to fight in a false cause, goes in search of Amis, who personates him in the ordeal by combat. He thus saves his friend, but in so doing perjures himself. Then follows the leprosy of Amis, and, after a lapse of years, his discovery of Amiles and cure. The legend of Amis and Amiles occurs in many forms with slight variations.

See L. Gautier, *Bibl. des chansons de geste* (1897); also the essay by W. Pater in *The Renaissance* (1893). The tale is published in good modern translations.

AMITERNUM, an ancient town of the Sabines, about 5m. N. of Aquila, in the broad Aternus valley from which, says Varro, it took its name. Stormed by the Romans in 293 B.C. it suffered in the wars of the Republic, but its fertility made it prosperous under the empire. It lay at the point of junction of four roads—the Via Caecilia, the Via Claudia Nova and two branches of the Via Salaria. There are considerable remains of an aqueduct, an amphitheatre and a theatre, all of the imperial period, while in the hill on which the village of S. Vittorino is built are some Christian catacombs. Sallust was born at Amiternum.

AMITOSIS, a term used in biology to denote the processes of cell division when the nucleus does not pass through the complicated series of changes normally associated with that phenomenon (see MIOSIS). Amitosis occurs in some of the lower forms of life and also in malignant growths (cancers) in the higher forms. (See CYTOLOGY.)

AMLWCH (ām'lōōch), market town of Anglesey, north Wales, situated on slightly rising ground on the north-east coast of the island, 15 m. N.W. of Beaumaris. Rather more than three miles distant on the coast are the remains of a Romano-British earthwork, while near at hand a mediaeval settlement is represented by the Llanllaiianau monastery. Amlwch seems to have been one of the fishing villages that grew up on the coast in association with these older sites.

In the 18th century the town came into prominence as the port for the rich copper mines of Parys mountain about two miles south of the town. There are traditions of the mines being worked intermittently from Roman days, but they reached their maximum

activity between 1768 and 1870, and they are now derelict. The population in 1841 was 6,217 and in 1931 was 2,561. Industries at one time included slate-quarrying, still carried on to a limited extent, shipbuilding, iron and brass foundries, alum, vitriol, manure and tobacco works. Amlwch is the terminus of the branch line from Gaerwen to Amlwch, formerly the Anglesey Central Railway, and now run by the L.M.S.R.

AMMAN, JOHANN CONRAD (1669-c. 1730), Swiss physician, was born at Schaffhausen and practised at Amsterdam. He was one of the earliest writers on the instruction of the deaf and dumb and first called attention to his method in his *Surdus loquens* (Amsterdam, 1692), which was often reprinted and was reproduced by John Wallis in the *Philosophical Transactions* (1698).

AMMAN, JOST (1539-91), Swiss artist, celebrated chiefly for his engravings on wood, was born at Zürich. Of his personal history little is known beyond the fact that he removed in 1560 to Nuremberg, where he continued to reside until his death in March 1591. A large number of his original drawings are contained in the Berlin collection of engravings. The genuineness of not a few of the specimens to be seen elsewhere is at least questionable. A series of copperplate engravings by Amman of the kings of France, with short biographies, appeared at Frankfurt in 1576. He also executed many of the woodcut illustrations for the Bible published at Frankfurt by Sigismund Feierabend. Another serial work, the *Panoplia omnium liberalium mechanicarum et sedentiarum artium genera continens*, containing 115 plates, is of great value. Amman's drawing is correct and spirited, and his delineation of details is minute and accurate.

AMMAN, a city of Palestine (see PHILADELPHIA).

AMMANATI, BARTOLOMEO (1511-92), Florentine architect and sculptor. He designed many buildings in Rome, Lucca and Florence, an addition to the Pitti Palace being one of his most celebrated works. He also built the beautiful bridge over the Arno, known as Ponte della Trinita. The three arches are elliptic, and, though very light and elegant, have resisted the fury of the river, which has swept away several other bridges at different times. Another important work was the fountain for the Piazza della Signoria. In 1550 Ammanati married the poet Laura Battiferri.

AMMANFORD, urban district, Carmarthenshire, Wales. Pop. (1931) 7,160. Situated near the junction of the river Amman with the Loughor 17 miles E. of Carmarthen town. This region has associations with Welsh folk-lore, particularly the hunting of Twrch Trwth (Mabinogion), and with the Physicians of Myddfai (a village in East Carmarthenshire). In the 18th and 19th centuries considerable quantities of local carboniferous limestone were burnt and carried long distances by road to West Wales for marling purposes. Ammanford grew with the export trade in coal, and its importance increased especially after 1885 as the use of anthracite spread. After 1900 rapid strides were made and Ammanford doubled its population in ten years—(1901) 3,500; (1911) 6,074. With the growing demand for anthracite in place of steam coal in modern industry (1918-28) and the amalgamation of almost all the anthracite collieries in South Wales into a large unit with world-wide influence and markets, Ammanford and district have escaped to some extent the universal depression in the coal industry since 1918. The population is still increasing and new pits were sunk in 1928.

Ammanford has a station on the Pantyffynon-Garnant branch of the G.W.R., and is also served by Pantyffynon and Tirdail on the Llanelly and Llandilo branch line over parts of which the G.W.R. and L.M.S.R. have running powers. Ammanford was made an urban district in 1903 and since 1918 is included in the East Carmarthenshire (Llanelly) parliamentary area.

AMMENDORF, a town lying on the river Elster between Halle and Merseburg, Prussian Saxony. Pop. (1925) 12,185. It is a centre for lignite and briquette industries, also producing machines, chemicals, paper and cardboard.

AMMETER: see INSTRUMENTS, ELECTRICAL.

AMMIANUS MARCELLINUS, Roman historian, was born about A.D. 325-330 at Antioch; the date of his death

is unknown but he must have lived till 391, as he mentions Aurelius Victor as the city prefect for that year. He was a Greek of noble birth. He entered the army at an early age and was sent to serve under Ursicinus, governor of Nisibis and *magister militae*. He returned to Italy with Ursicinus, when he was recalled by Constantius II. and accompanied him on the expedition against Silvanus the Frank. With Ursicinus he went twice to the East and barely escaped with his life from Amida or Amid (mod. Diarbekr), when it was taken by the Persian king Shapur (Sapor) II. When Ursicinus lost his office and the favour of Constantius, Ammianus seems to have shared his downfall; but under Julian, Constantius's successor, he regained his position. He accompanied Julian in his campaigns against the Alamanni and the Persians; after the death of Julian he took part in the retreat of Jovian as far as Antioch, where he was living in 371. Eventually he settled in Rome, where, at an advanced age, he wrote (in Latin) a history of the Roman empire from the accession of Nerva to the death of Valens (96-378), thus forming a continuation of the work of Tacitus. This history (*Rerum Gestarum Libri XXXI.*) was originally in 31 books; of these the first 13 are lost, the 18 which remain cover the period from 353 to 378. It is a clear, comprehensive and impartial account of events by a contemporary of soldierly honesty, independent judgment and wide reading. His style is generally harsh, often pompous and extremely obscure, occasionally even journalistic in tone, but the author's foreign origin and his military life and training partially explain this. Further, the work being intended for public recitation, some rhetorical embellishment was necessary, even at the cost of simplicity. Though a professional soldier Ammianus gives excellent pictures of social and economic problems, and in his attitude to the non-Roman peoples of the empire he is far more broad-minded than Livy and Tacitus. In his description of the empire—the exhaustion produced by excessive taxation, the financial ruin of the middle classes, the progressive decline in the morale of the army—we find the explanation of its fall before the Goths 20 years after his death.

The work was discovered by Poggio, who copied the original ms. *Ediit princeps* (bks. 14-26) by Sabinus, 1474; completed by Accursius, 1533; with variorum notes, by Wagner-Erfurdt, 1808. Later editions of text, V. E. Gardthausen, 1874-75; C. U. Clark, 1910-15. English translations by P. Holland, 1609; C. D. Yonge, 1862. See F. Liesenberg, *Der Sprache des Ammianus Marcellinus* (1888-90); Max Büdinger, *Ammianus Marcellinus und die Eigenart seines Geschichtswerkes* (1895); S. Dill, *Roman Society in the Last Century of the Western Empire* (1898); T. R. Glover, *Life and Letters in the Fourth Century* (1901); A. M. Harmon, "The Clausula in Ammianus Marcellinus," *Conn. Acad. Arts and Sci., Trans.*, vol. xvi, pp. 119-245 (New Haven, 1910); W. Ennslein, *Zur Geschichtsschreibung und Weltanschauung des Ammianus Marcellinus* (1923).

AMMINES, in chemistry, compounds resulting from the addition of ammonia, NH₃, to metallic salts or other binary chemical compounds. (See CHEMISTRY: *Inorganic*; CO-ORDINATION, *VALENCY*.) The ammine formed from copper sulphate is the essential constituent in Schweitzer's reagent which is used as a solvent for cellulose in the preparation of one kind of artificial silk.

See A. Werner, *New Ideas on Inorganic Chemistry* (1911); M. M. J. Sutherland, *The Metal Ammines* (1928).

AMMIRATO, SCIPIONE (1531-1601), Italian historian, born at Lecce, in the kingdom of Naples, lived under the patronage of Duke Cosimo I., of Florence, who gave him a residence at the Medici Palace and the Villa Zopaja on the understanding that he should write his *Istorie Fiorentine* (1600), the work by which he is best known.

AMMON: see EGYPT: *Religion*.

AMMON, CHRISTOPH FRIEDRICH VON (1766-1850), German theological writer and preacher, was a very voluminous author. His principal theological work was the *Fortbildung des Christenthums zur Weltreligion* (Leipzig, 1833-40). *Entwurf einer reinbiblischen Theologie* appeared in 1792 (2nd ed. 1801); *Summa Theologiae Christianae* in 1803 (other eds., 1808, 1816, 1830); *Das Leben Jesu* in 1842, and *Die wahre und falsche Orthodoxie* in 1849.

See Herzog-Hauck *Realencyklopädie*; Otto Pfeleiderer *The Development of Theology in Germany since Kant*, pp. 89 seq.

AMMONIA and its salts have been known from very early times, sal-ammoniac being mentioned by Pliny. By the

action of alkalis on this, Basil Valentine obtained free ammonia in the 15th century; later, ammonia was obtained by distilling the hoofs and horns of oxen, and was therefore called "spirits of hartshorn." J. Priestley was the first to isolate gaseous ammonia (1774), which he called "alkaline air." In 1777 K. W. Scheele showed it to contain nitrogen, and shortly afterwards C. L. Berthollet ascertained its composition to be NH_3 .

Ammonia is found in small quantities as the carbonate in the atmosphere, being produced from the putrefaction of nitrogenous animal and vegetable matter; ammonium salts are also found in small quantities in rain-water, whilst the chloride and sulphate are found in volcanic districts. Fertile soils, sea-water, and plant and animal liquids (such as urine) also contain ammonium salts.

Ammonia is obtained by the dry distillation of animal and vegetable products, and also by the decomposition of its salts (usually the chloride or sulphate) by alkaline hydroxides or slaked lime: $2\text{NH}_4\text{Cl} + \text{Ca}(\text{OH})_2 = 2\text{NH}_3 + \text{CaCl}_2 + 2\text{H}_2\text{O}$. It may be obtained by the action of water on, e.g., magnesium nitride. Large quantities of ammonia and its salts (usually the sulphate) are obtained from the ammoniacal liquor of the gas works. Such ammonia is, however, difficult to purify from the pyridine which it contains, and the purest ammonia is now obtained synthetically.

The reversible reaction $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$ evolves heat when it produces ammonia, and therefore it becomes less favourable the higher the temperature; but as it also takes place with a decrease in volume, it is favoured by an increase of pressure. In practice a compromise is effected, for, although at 450°C . it would only be possible to effect combination of 0.24% of the gases (if present in the theoretical proportion) under atmospheric pressure, and at 550°C . only 0.08%, yet at the lower temperature reaction is so slow as to be unprofitable in working. The higher temperature is therefore chosen, and under 200 atmospheres pressure (as used by Haber) the equilibrium concentration is 12% and under 1,000 atmospheres (as used by Claude) it is 40%. The nitrogen (often from liquid air) and hydrogen (often from purified "water gas") are dried, compressed, and circulated at 550°C . over a catalyst, the best being a very pure iron, obtained by reducing the oxide in a current of hydrogen at this temperature. The ammonia pro-

the liquid boils at -33.7°C ., and solidifies at -78°C . to a mass of white crystals. It is extremely soluble in water, one volume at 0°C . and normal pressure absorbing 1,300 volumes of ammonia, and a saturated solution at 15°C . contains 36%. It forms two hydrates with water, $\text{NH}_3 \cdot \text{H}_2\text{O}$ and $2\text{NH}_3 \cdot \text{H}_2\text{O}$, both of which melt at -79°C ., i.e., only one degree below the melting point of pure ammonia. All the ammonia contained in an aqueous solution of the gas may be expelled by boiling. It does not support combustion and it does not burn readily unless mixed with oxygen, in which case it burns with a pale greenish flame. Ammonia gas has the power of combining with many substances, particularly with metallic halides; thus, with calcium chloride it forms the compound $\text{CaCl}_2 \cdot 8\text{NH}_3$, and consequently calcium chloride cannot be used for drying the gas. With silver chloride it forms two compounds— $\text{AgCl}_3 \cdot \text{NH}_3$ at temperatures below 15°C ., and $2\text{AgCl}_3 \cdot \text{NH}_3$ above 20°C . When heated, these substances liberate ammonia and the silver chloride remains; by this method M. Faraday was able to liquefy ammonia for the first time (1823). Ammonia is decomposed into its elements at a red heat or by the passage of electric sparks. Chlorine takes fire when passed into strong ammonia solutions, nitrogen and hydrochloric acid (or ammonium chloride) being formed, and unless the ammonia is present in excess the highly explosive nitrogen chloride NCl_3 is also produced. With iodine it reacts to form nitrogen iodide, which was originally supposed to contain nitrogen and iodine only; later, however, it was found to contain hydrogen also. F. D. Chattaway showed it to be $\text{N}_2\text{H}_4\text{I}_2$, and O. Silberrad further showed its constitution to be $\text{NH}_3 \cdot \text{NI}_3$. The hydrogen in ammonia is capable of replacement by metals, thus magnesium burns in the gas with formation of the nitride, Mg_3N_2 , and when the gas is passed over heated sodium or potassium, sodamide, NaNH_2 , or potassamide, KNH_2 , is formed.

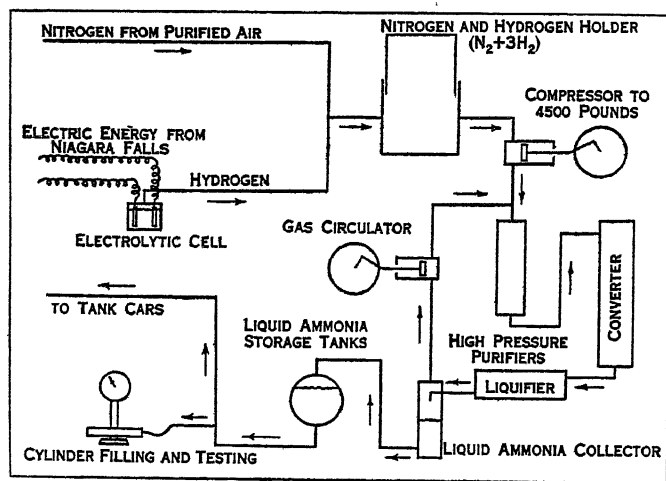

Liquid ammonia is used for the artificial preparation of ice. It shows a slight but definite electrical conductivity, though it is not certain what ions are responsible for this, and salts dissolved in it are fairly strongly dissociated into ions, but not nearly so extensively as in aqueous solutions. Moreover, certain metals dissolve in it to give very deep blue solutions which may possibly contain, e.g., NaNH_2 , $\text{Ba}(\text{NH}_2)_2$, etc. The works of E. C. Franklin (*Amer. Chem. J.*, 1899 *et seq.*), C. A. Kraus (e.g., *J. Amer. Chem. Soc.* 1922, 44, p. 1949, 1925, 42, p. 749) and C. Frenzel should be consulted for fuller details as to solutions in liquid ammonia.

One of the most characteristic properties of ammonia is its power of combining directly with acids to form salts; thus with hydrochloric acid it gives ammonium chloride (sal-ammoniac), and with nitric acid ammonium nitrate, etc. It is of great interest, however, that ammonia and hydrochloric acid will not react if they are both perfectly dry (H. B. Baker; see DRYNESS, CHEMICAL); moreover, perfectly dry ammonium chloride does not exhibit the reverse phenomenon of dissociation into its components, which is so characteristic of ammonium salts.

The aqueous solution of ammonia is very basic in its reactions, but it is not very definite as to whether this is due to an ammonium hydroxide, NH_4OH , to free ammonia as such, or to ammonia allied in some way with water, for there is doubtless an equilibrium involved:

According to A. Hantzsch and T. S. Moore, the apparent "strength" of ammonia as a base is very low, for only about 1% of the total ammonia is present in the form of ions in decinormal (i.e., 0.1%) aqueous solution, but as these may be derived from a relatively small proportion of NH_4OH , it is possible that the latter molecule is fairly strongly ionized. When boiled, solutions of ammonium salts tend to lose ammonia, and if the acid is "weak" both it and the ammonia may be boiled away completely, but as most of the ammonia may be present in a form other than NH_4OH , this again is no evidence that the latter is a weak base, especially as the above equilibria would tend to replace the volatile NH_3 at the expense of the NH_4OH . From a consideration of the ease of dissociation of the double sulphates $\text{CuSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ (where $\text{M} = \text{NH}_4, \text{K}, \text{Rb}$ or Cs), R. M. Caven places

DIAGRAM SHOWING HOW NITROGEN FROM THE AIR AND HYDROGEN FROM AN ELECTROLYTIC CELL ARE CONVERTED INTO AMMONIA

duced is either passed through a refrigerator and collected as a liquid, or absorbed in water.

Another industrial process of some importance in the production of ammonia is that whereby calcium cyanamide, CaCN_2 , is heated under 3 atmospheres pressure with water in order to liberate traces of acetylene, and then under 11 atmospheres at 180°C . with a current of superheated steam, the resulting ammonia being blown over and collected. For fuller details of these processes see NITROGEN, FIXATION OF.

Ammonia is a colourless gas possessing a characteristic pungent smell and a strongly alkaline reaction; it is lighter than air, its specific gravity being 0.589 (air=1). It is easily liquefied and

ammonium hydroxide as a base between rubidium and caesium hydroxides in strength.

Numerous attempts have been made to isolate the radical NH_4 , but the most that has been achieved is to obtain evidence as to its existence in an amalgam or in solution. The addition of sodium amalgam to a cold concentrated solution of ammonium chloride gives a spongy mass which resembles the amalgams of the alkali metals in some respects but not in others; it readily decomposes into ammonia and hydrogen. H. H. Schlubach and F. Ballouf added very cold ammonium chloride to a solution of potassium in liquid ammonia at -70°C , and, as only one-third of the theoretical amount of hydrogen was evolved and solubility would not account for more than a trace of the rest, it is assumed that the free ammonium, NH_4 , remains in solution; the remainder of the hydrogen is given off at -40°C .

The precise constitution of the ammonium radical or ion has been a matter of much speculation, but W. H. Mills and E. H. Warren have now shown that the nitrogen atom is situated at the centre of a regular tetrahedron with the hydrogen atoms at the four corners, and this has been confirmed by Mills, J. D. Parkin and W. J. D. Ward (*see* STEREOCHEMISTRY for further details). The ammonium ion and the methane molecule therefore have similar structures, as might be anticipated on the electronic

theory, for, if they are written as (1) and (2) respectively (where, in each case, the crosses represent electrons originally belonging to the N and C atoms, and the dots those belonging to the H atoms), it is seen that the nitrogen atom shares 8 electrons equally with hydrogen atoms and has lost one of its five electrons, thereby becoming positively charged, whereas the carbon atom has a half share in its own four electrons and in four others, thereby remaining neutral.

Ammonia finds a wide application in organic chemistry as a synthetic reagent; it reacts with alkyl iodides to form amines (*q.v.*), with esters to form amides (*q.v.*), and with halogen fatty acids to form amino-acids; it combines with isocyanic esters to give alkyl-ureas, and with the mustard oils to give alkyl-thioureas. Aldehydes also combine directly with ammonia.

The alkyl-amines, which may be regarded as derived from ammonia by successive replacement of hydrogen atoms by alkyl groups, are not very strong bases, but the trialkyl-amines react with alkyl iodides to give tetra-alkyl-ammonium iodides, $\text{NR}_3 + \text{RI} = \text{NR}_4\text{I}$, which resemble the alkali-metal iodides, and this resemblance between alkali metals and the tetra-alkyl-ammonium group is still more pronounced in the corresponding hydroxides (obtained by the action of moist silver oxide on the iodide of the base), for these are strongly caustic bases which absorb carbon dioxide and generally resemble potassium hydroxide. The relative stability of the quaternary ammonium grouping is further illustrated by the fact that the corresponding amalgams are much more stable than that of ammonia. H. N. McCoy and W. C. Moore obtained a tetramethylammonium amalgam which did not decompose below 10°C . Moreover, Schlubach and Ballouf, using a method analogous to that described in the case of the ammonium radical, found evidence for the existence of a tetraethylammonium which was stable in liquid ammonia at the ordinary temperature if kept in an atmosphere of nitrogen. When all four alkyl groups of a quaternary ammonium salt are different, the compound can be resolved into optical isomerides, and W. J. Pope and S. J. Peachey resolved benzylphenylallylmethylammonium salts into dextro- and laevo-rotatory forms (*see* STEREOCHEMISTRY).

Salts.—Ammonium fluoride, NH_4F , may be obtained by neutralizing ammonia with hydrofluoric acid; it has a sharp saline taste, and the crystals are very soluble in water; it decomposes silicates on being heated with them. It is a powerful preservative.

Ammonium chloride, NH_4Cl . (*See* SAL-AMMONIAC.)

Ammonium bromide, NH_4Br , can be prepared by the direct action of bromine on ammonia. It crystallizes in colourless prisms which have a saline taste and are very soluble in water. Like the chloride, it sublimes on heating. It is sometimes used medicinally instead of potassium bromide.

Ammonium iodide, NH_4I , can be prepared by the action of hydriodic acid on ammonia. It is soluble in alcohol and exceedingly so in water. It turns yellow on keeping, unless kept in sealed tubes away from light. With iodine it gives the tri-iodide, NH_4I_3 ; if chlorine is passed into its solution in which iodine is suspended, the comparatively stable dichloroiodide, $\text{NH}_4\text{Cl}_2\text{I}$, is obtained.

Ammonium chlorate, NH_4ClO_3 , decomposes at about 100°C . into nitrogen, oxygen and chlorine. The perchlorate, NH_4ClO_4 , obtained from an alkaline perchlorate and an ammonium salt, has been used in high-explosive shell, but is rather too sensitive to shock.

Ammonium carbonates. The commercial salt is known as sal volatile or salt of hartshorn; it is obtained by heating the chloride or sulphate with chalk and condensing the vapours. When resublimed, it forms hard fibrous masses of composition $\text{NH}_4\text{HCO}_3 + \text{NH}_2\text{COONH}_4$ (*i.e.*, bicarbonate and carbamate in molecular proportion), or, more probably, $(\text{NH}_4)_2\text{CO}_3 + 2\text{NH}_4\text{HCO}_3 + \text{H}_2\text{O}$, which is a sesquicarbonate; it possesses a strongly ammoniacal smell. The normal carbonate, $(\text{NH}_4)_2\text{CO}_3$, is obtained by saturating a concentrated solution of the foregoing with ammonia; it can be obtained in a crystalline condition, but readily loses ammonia on exposure and reverts to the sesquicarbonate.

The bicarbonate, NH_4HCO_3 , is obtained by saturating a solution of the commercial carbonate with carbon dioxide; it is sparingly soluble in water and readily loses carbon dioxide.

Ammonium thiocyanate (or sulphocyanide), NH_4NCS , can be obtained from carbon disulphide and ammonia; it isomerises to thiourea, which is used in the rubber industry; it is also of use in quantitative analysis (*see* CHEMISTRY: ANALYSIS).

Ammonium nitrate, NH_4NO_3 , prepared from the acid and ammonia, exists in four different crystalline forms which are, respectively, stable over the temperature ranges: below -16° , -16° to 32° , 32° to 84° , and 84° to 169.6° (the melting point). Its dissolution in water produces a considerable lowering of temperature which is utilized in freezing mixtures. On being gently heated it is decomposed into water and nitrous oxide: $\text{NH}_4\text{NO}_3 = \text{N}_2\text{O} + 2\text{H}_2\text{O}$.

Ammonium nitrite, NH_4NO_2 , is formed in the oxidation of ammonia by ozone or hydrogen peroxide; it is best obtained by double decomposition of sodium nitrite and ammonium chloride, the resulting sodium chloride being much less soluble; if silver nitrite is used the product is purer. The solution can be concentrated to give crystals which can be sublimed in a vacuum at 80°C , but they readily decompose to give water and nitrogen: $\text{NH}_4\text{NO}_2 = \text{N}_2 + 2\text{H}_2\text{O}$.

Ammonium phosphates. The normal phosphate, $(\text{NH}_4)_3\text{PO}_4$, can be obtained by adding excess of ammonia to the acid phosphate, $(\text{NH}_4)_2\text{HPO}_4$, or to a concentrated solution of the acid; its solution readily loses ammonia. The diammonium hydrogen phosphate, $(\text{NH}_4)_2\text{HPO}_4$, is obtained by evaporating the foregoing solutions; on heating, the crystals melt and decompose, leaving a residue of metaphosphoric acid, HPO_3 . The dihydrogen phosphate, $(\text{NH}_4)_2\text{H}_2\text{PO}_4$, crystallises from solutions which are distinctly acidic with phosphoric acid.

Ammonium sodium hydrogen phosphate, $(\text{NH}_4)\text{NaHPO}_4$, is known as microcosmic salt (*q.v.*).

Ammonium sulphate, $(\text{NH}_4)_2\text{SO}_4$, is prepared from the ammoniacal liquor of gas-works (*see* GAS: MANUFACTURE) and purified by recrystallization. The aqueous solution tends to lose ammonia on boiling. Its chief use is as an artificial manure, and much of that being sold for this purpose is made from synthetic ammonia.

Ammonium persulphate, $(\text{NH}_4)_2\text{S}_2\text{O}_8$, is prepared by the electrolytic oxidation of a cold, saturated solution of the sulphate, in the presence of dilute sulphuric acid, a high anodic current density being used; it is more conveniently obtained by double decomposition from ammonium chloride and sodium persulphate. It is

difficult to prepare in a state of high purity, and is very soluble in cold water (58 grams in 100 grams of water at 0° C.).

Ammonium sulphide, $(\text{NH}_4)_2\text{S}$, is obtained as micaceous crystals by passing sulphuretted hydrogen and a slight excess of ammonia through a well-cooled vessel. Excess of the sulphuretted hydrogen gives rise to the hydrosulphide, NH_4HS . Both are very soluble white solids. The former is usually sold as a concentrated aqueous solution, which finds a considerable use in analysis. The sulphide solution dissolves sulphur to give a series of ill-defined polysulphides.

According to A. E. H. Tutton, many of the ammonium salts display a close resemblance to the corresponding salts of rubidium and caesium in their crystallographic characteristics, the similarity being especially striking in the case of the former metal.

Ammonia readily combines with many metallic salts (as with calcium and silver chlorides, above) to give ammines (*q.v.*), which are often of great theoretical interest. See also MERCURY for the "infusible" and "fusible white precipitates" of pharmacy.

Compounds are known which may be regarded as derived from ammonia by the replacement of hydrogen atoms by the sulpho-group; thus, potassium ammon-trisulphonate, $\text{N}(\text{SO}_3\text{K})_3$, $2\text{H}_2\text{O}$, is obtained as a crystalline precipitate by the addition of excess of potassium sulphite (or metabisulphite) to a solution of potassium nitrite: $\text{KNO}_2 + 3\text{K}_2\text{SO}_3 + 2\text{H}_2\text{O} = \text{N}(\text{SO}_3\text{K})_3 + 4\text{KOH}$. It can be recrystallized from alkaline solution, and on boiling with water is converted successively into the disulphonate, $\text{NH}(\text{SO}_3\text{K})_2$, and monosulphonate, $\text{NH}_2\text{SO}_3\text{K}$, the latter being the salt of the stable aminosulphonic acid. The chief interest of the disulphonate lies in the fact that its hydrogen atom is acidic, for the corresponding ammonium salt, $\text{NH}(\text{SO}_3\text{NH}_4)_2$, gives a triammonium salt $\text{NH}_4\text{N}(\text{SO}_3\text{NH}_4)_2$, and both of these are formed by direct union of sulphur trioxide and ammonia. For further details of such compounds, the works of E. Divers and of F. Raschig should be consulted, especially the latter's *Schwefel- und Stickstoffstudien*, 1924.

Hydrazine. If a solution of sodium hypochlorite is added to a fairly concentrated solution of ammonia containing 0.2% of glue, hydrazine, NH_2NH_2 , or chloroamine, NH_2Cl , is produced according to the conditions; the latter is fairly stable and may be distilled in a vacuum.

Detection and Estimation.—Solutions of ammonia and ammonium salts, even if very dilute, give a distinct yellow or yellowish-brown coloration with Nessler's solution, owing to the formation of a complex iodide, $\text{NH}_4\text{I}_2\text{H}_2\text{O}$, which is obtained as a precipitate from stronger solutions; this is also the basis of a colorimetric method for estimating minute traces of ammonia in drinking-water. Larger quantities of ammonia or its salts can be detected by the evolution of the characteristic smell of the free ammonia on heating with caustic alkalis or lime. The quantitative estimation may be effected by (1) distillation of salts or ammoniacal liquors with sodium or potassium hydroxide and absorption of the liberated ammonia in an excess of standard sulphuric acid, the excess being titrated by alkali; (2) by absorption of ammonia in hydrochloric acid and precipitation as the chloroplatinate, $(\text{NH}_4)_2\text{PtCl}_6$; or (3) by the addition of neutral formaldehyde to a neutral solution of an ammonium salt, whereby hexamethylenetetramine is formed and the acid originally in combination with the ammonia is set free and may be titrated: $4\text{NH}_4\text{Cl} + 6\text{CH}_2\text{O} = (\text{CH}_2)_6\text{N}_4 + 4\text{HCl} + 6\text{H}_2\text{O}$. (A. D. M.)

(See REFRIGERATION AND ICE MANUFACTURE.)

AMMONIACUM or **GUM AMMONIAC**, a gum-resin exuded from the stem of a perennial herb (*Dorema ammoniacum*), family Umbelliferae. The plant grows to the height of 8 or 9 ft., and its whole stem is pervaded with a milky juice, which oozes out on an incision being made at any part. This juice quickly hardens into round tear-like bodies, forming the "tear ammoniacum" of commerce. "Lump ammoniacum," the other form in which the substance is met with, consists of aggregations of "tears," frequently incorporating fragments of the plant itself, as well as other foreign bodies.

AMMONITE, a group of extinct Mollusca, belonging to the class Cephalopoda (*q.v.*), which also includes the octopus and

cuttle-fish. They possessed an external shell, coiled in a flat spiral and divided into chambers very similar to that of the modern nautilus (*q.v.*). Many reached a great size, the largest, *Pachydiscus seppenradensis*, from the Cretaceous of Westphalia, having a shell 6 ft. 8 in. in diameter. The Ammonites began in the Carboniferous period and became extinct at the end of the Cretaceous.

AMMONITES, a people of ancient Transjordan, believed to be allied to Israel, but still more closely to Moab. Their home was to the north and north-east of Moab, and their chief city, Rabbath-Ammon (later Philadelphia, the modern Ammān) stood on the banks of a tributary of the Jabbok. Like the Moabites, the Ammonites seem to have combined the pastoral life with a limited amount of agriculture. Their religion was similar to that of their neighbours, but was notorious for the extent to which human sacrifice was offered to their god Milcom or Melek.

It is, of course, impossible to discuss the actual history of Ammon, but the tribe is occasionally mentioned in the annals of other peoples, especially those of Israel. Belonging to the same general Hebrew stock, they had dispossessed the aborigines, whom they called Zamzumim, and settled down before the time of the Exodus, in a district bounded to the north by the river Jabbok. Expelled by Sihon from the northern parts of their territory and driven eastwards, they had been left unmolested by the Israelites in their passage to Palestine, but, nevertheless, had remained hostile to them. They were in alliance with David, but on the death of Nahash made an effort to escape from association with Israel. The country was overrun, Rabbath was captured, and the people reduced to servitude.

We hear but little of Ammon during the period of the Hebrew kingdoms, but Shalmaneser III. speaks of a small contingent (1,000 men) in the allied army which met him at Karkar (see АНАВ), and a century later Tiglath-pileser III. and his successors received tribute from Ammon. They do not seem to have been concerned in the great revolt of 701, and Sennacherib was content to receive tribute from them. In 587 they supported Zedekiah at the beginning of his rebellion against Nebuchadnezzar, but, apparently, submitted; and Ammonite troops were amongst those that sacked Jerusalem. From this time onwards implacable enmity seems to have existed between Israel and Ammon. It was at the instance of a king of Ammon that Gedaliah was murdered, and the partial depopulation of Judah saw numbers of them entering the country. In his attempt to restore the purity of the Judæan community, Nehemiah found that a certain Tobiah, an Ammonite, was one of his bitterest opponents, and this tribe offered a strenuous resistance to the aggrandizing policy of the Maccabean princes. They still formed a large community in the days of Justin Martyr. (T. H. R.)

AMMONTUM exists only in combination as a monovalent basic radicle, NH_4 . (See AMMONIA.)

AMMONTUS HERMIAE (5th century A.D.) Greek philosopher, the son of Hermeias. He taught at Alexandria and had among his scholars Asclepius, John Philoponus, Damascius, and Simplicius. His commentaries on Plato and Ptolemy are lost. Of his commentaries on Aristotle we have—(1) one on the *Isagoge* of Porphyry (Venice, 1,500 fol.); (2) one on the *Categorias* (Venice, 1,503 fol.), the authenticity of which is doubted by Brandis; (3) one on the *De Interpretatione* (Venice, 1,503 fol.). They are printed in Brandis's scholia to Aristotle, forming the fourth volume of the Berlin *Aristotle*; they are also edited (1891–99) in A. Busse's *Commentaria in Aristot. Graeca*. The special section on Fate was published separately by J. C. Orelli, *Alex. Aphrod., Ammonii, et aliorum de Fato quae supersunt* (Zürich, 1824). A life of Aristotle, ascribed to Ammonius, but with more accuracy to John Philoponus, is often prefixed to editions of Aristotle. It has been printed separately, with Latin translation and scholia, at Leyden, 1621, and Helmstadt, 1666, and at Paris, 1850. Other commentaries on the *Topics* and the first six books of the *Metaphysics* still exist in manuscript.

For a list of his works see J. A. Fabricius, *Bibliotheca Graeca*, v. 704–707; C. A. Brandis, *Über d. Reihenfolge d. Bücher d. Aristot. Org.*, 283 f.; K. Prantl, *Gesch. d. Logik*, i. 642.

AMMONIUS SACCAS (c. 160–242), the founder of Neoplatonism, was originally an Alexandrian porter, and, according to Porphyry as quoted by Eusebius, a Christian. His self-instruction in philosophy was thorough enough to attract disciples of such calibre as Longinus, the grammarian, Origen, and Plotinus. Since he designedly left no writings, practically nothing is known about his doctrines. From casual remarks of Nemisius and Hierocles, he is said to have taught the incorporeity of the soul and to have attempted a reconciliation of Plato and Aristotle. It is impossible to determine to what extent he influenced Plotinus.

AMMUNITION, a military term which includes projectiles used with ordnance, rifles and similar weapons, together with the requisite propellents, fuses, cartridges and means of ignition.

I. AMMUNITION FOR ORDNANCE

HISTORICAL

Berthold Schwartz, a German monk, is credited with the invention of cannon in Europe in 1313. The first projectiles used with these primitive weapons were bolts, darts, stone shot and "langridge." The darts, made of iron and feathered with brass, were wrapped in leather to prevent windage. "Langridge" consisted of bits of iron, nails, flints, and similar material, which were ordinarily contained in a sack or container and may be considered the forerunner of grape and case shot. The propellant charge was gunpowder, fired by red hot bars or spikes. Round shot of metal were known in early times but did not entirely supersede stone shot until the 17th century, for economical and practical reasons.

The use of shell was advocated at a very early date, but the absence of fuses made their successful employment dangerous and difficult. The original shell were known as "grenades" when spherical, and "bombs" when oblong, the word shell itself being of later introduction. In 1376 shell were used at Jadra by the Venetians, and later, in 1421, shell were employed at the siege of St. Boniface in Corsica. These shell were fitted with a primitive fuse consisting of "sheet iron tubing with priming." At about this time also, the method of ignition by red hot iron was superseded by priming the vent with loose powder. The shell of this period consisted of two hemispheres of stone or bronze joined with hoops and hinged. Shot still remained the paramount projectile for guns. About the middle of the 15th century case shot were used at the siege of Constantinople, and the first incendiary shell was invented by Valturio in 1460.

Improvements were slow in these early times but the use of metal, particularly cast iron, was gradually extended as the guns improved in design. In the 16th century "hail shot" were used, which were similar to case shot with the addition of a bursting charge, and they also had a primitive match fuse which was ignited by the propellant charge. A German projectile of this type was invented by Zimmerman in 1573 in which the bursting charge filled half the container. In 1543 shell filled with "wild-fire" were known in England, and the use of shell in Europe was on the increase. In 1579 Stephen Batory, king of Poland, suggested the employment of red hot shot, but little use was made of the device. The idea persisted, however, and was fully exploited at the siege of Gibraltar in 1779–1783.

In 1596 Sebastian Hälle suggested the idea of the modern time fuse and modern percussion fuses; but the chemistry of the day could not provide the requisite chemicals, and the fuse of the time remained the simple iron tube filled with composition. During the 17th century attempts were made to improve fuses, and in 1650 a primitive fuse was tried, based on the principle of a flint lock. It was not successful, and the gunner still awaited a satisfactory "percussion powder." In 1672 a gunner in the service of Van Galen, prince bishop of Munster, invented the carcass. It contained incendiary matter and had a primitive fuse.

This projectile developed into a spherical projectile with vents. Its use persisted until the 19th century, when it disappeared with muzzle loading ordnance. In 1681 bombs were fired at sea by the French at the bombardment of Algiers. During this period smoke shell made their appearance, being paper projectiles which replaced earlier smoke balls.

General improvement in ammunition occurred in the 18th century, and in 1784 Shrapnel invented the projectile which bears his name. It differed in principle from previous similar projectiles in that its charge was in reality an opening charge and was not intended to impart velocity to the contained bullets. The use of shell was becoming more general and was being extended to guns as well as mortars. The standard material was cast iron, but bronze, lead, brass and glass were also tried.

The 19th century witnessed enormous improvements in war material generally. In 1800 Howard isolated mercury fulminate, and shortly afterwards Forsyth patented a percussion mixture and Hawkins invented a percussion cap. The consequent development of fuses was rapid. Percussion fuses were introduced about 1842 and improved means of ignition led to practicable time fuses of modern principle in 1864 and time and percussion fuses in 1867. The evolution of these types led logically to the modern fuse. In 1855 the introduction of Martin's shell, which was filled with molten iron, made red hot shot obsolete. Quilted grape and Caffin's grape were both in use but died out with muzzle-loading ordnance.

The introduction of rifled ordnance involved considerable changes in ammunition, and elongated projectiles were introduced and were provided with means of rotation, such as lead coats, studs and gas checks, leading finally to the modern projectile with driving bands. The shell began gradually to oust the shot. In 1865 steel shot were introduced for use against iron-clads, but owing to expense they were superseded by Palliser chilled iron shot in 1867. In 1887 forged steel armour-piercing shot were introduced and lingered on in various services until quite modern times, but all shot of this type have been largely superseded by armour piercing shell. The development of shell was rapid, and between 1880–1890 steel became the paramount material. The development of common high explosive and armour-piercing shell now becomes a matter of modern history. Segment shell and ring shell were born and died. To sum up, the 19th century saw the gradual decline of shot and case shot and the rise of the modern shell.

TECHNICAL

A round of ammunition for a gun comprises four main constituents: (a) the projectile, with its filling, (b) the cartridge, (c) the means of ignition and (d) the fuse.

The fuse is screwed into the projectile, normally at the nose, but sometimes in the base, and the means of ignition may be either an integral part of the cartridge or a separate component.

PROJECTILES

Types of Projectiles.—Projectiles for ordnance may be divided into two main classes, shot and shell. The only shot now found in modern armaments are proof shot, practice shot, paper shot and case shot. Proof shot are solid shot used for proving ordnance and charges. Practice shot are solid shot used for practice purposes. Paper shot are used to test gun mountings which cannot fire service projectiles in peace time, owing to their siting. They are made mainly of paper or pulp and their weight is calculated to exert the same stress on the mounting as a service round, but they break up in the bore when fired. Case shot generally consist of three or more long steel segments held in position inside a thin, tinned canister, the whole being filled with bullets. The top and bottom are formed of steel plates and in larger natures, the shot is stiffened by a central bolt. It is not much used in modern equipments.

The natures of shell now used are: common pointed or C.P. shell; high explosive or H.E. shell; shrapnel shell; armour-piercing or A.P. shell; and special shell, of kinds such as gas, smoke, star (illuminating) and incendiary. These various types of shell

are employed because different effects are desired on the target, but there are certain properties common to all shell. For example, they must not break up in the gun when it is fired; they should give long ranges and accurate shooting and they should be cheap and easy to manufacture. It can, therefore, be seen that the design of a shell is a compromise between conflicting qualities, but as a result of experience the following facts are generally true.

Weight.—Roughly, the weight, in pounds, of a shell suitable for a given gun is half the cube of the calibre in inches.

Length.—A shell should be at least 2 calibres but normally does not exceed $4\frac{1}{2}$ calibres in length. If a ballistic cap or hollow point is fitted the maximum length may be increased.

Shape.—The modern shell consists usually of a cylindrical body with a tapering head. An ogival head is generally considered the best shape for overcoming air resistance and ensuring accuracy but conical and other smooth shapes may be employed. Theoretically, with high velocity shell, the longer the head the greater is the range obtained, but in practice the length of head is limited by considerations of accuracy. With low velocity projectiles an increase of range may be obtained by stream lining or boat tailing the base, but the use of this device is restricted by practical considerations.

Material.—Modern shell are ordinarily all made of cast or forged steel.

Driving Bands.—To obtain rotation, a copper or alloy band is pressed into an undercut groove near the base of the shell. This centres the projectile and in conjunction with the rifling of the gun, gives the necessary rotation. With heavy shell two or three bands may be employed.

Caps.—To increase the penetration of pointed projectiles used against armour, solid caps of steel may be fitted over the points and fixed by soldering and indenting. These caps are employed with C.P. and A.P. shell.

C.P. Shell.—These shell are intended for the attack of light armour. They are prepared to take a base fuse and are filled with gunpowder or high explosive. Sometimes the points may be specially hardened and fitted with caps to give better penetration. (See fig. 1.)

H.E. Shell.—High explosive, as a filling for artillery shell, was first suggested by Turpin in 1886, who advocated the use of picric acid in a dense form. With slight modifications, it was adopted by the French as melinite, by the Germans as granatfüllung 88, by the British as lyddite, and by the Japanese as shimose. Modern British H.E. shell are normally of forged steel with solid bases, a special steel base plate being fitted in a recess in the base to give added strength. The walls may be comparatively thin, which gives good effect against material, or, alternatively, the walls may be thick enough to give good effect against personnel. The nose of the shell is prepared to take a fuse. In some countries solid bases are not considered essential in these shell. Explosives used as H.E. shell fillings are ordinarily picric acid, TNT (trinitro-toluene), and amatol, which is a mixture of TNT and ammonium nitrate. Other substances used are dinitro-benzene trini-

troanisol and guncotton, and, during the World War, many other fillings were tried. These explosives are generally inert and not easily detonated, and hence an exploder system is ordinarily found between the fuse and the filling itself. In some cases, where detonation gives little or no smoke, some smoke-producing mixture is included in filled shell to assist observation of fire. A typical modern British H.E. shell is illustrated in fig. 2. The steel body is stout, giving good fragmentation. The filling is amatol, with a proportion of TNT to facilitate detonation. The exploder system in this particular case is represented by a gaine and an exploder. Fig. 3 illustrates a modern German H.E. shell evolved during the war. The filling calls for little comment. There are several points of interest in comparison with earlier shell. The base is closed by an adapter, which is contrary to British practice. Three driving bands are employed and a decoppering ring is fitted. Two fuse holes are provided, which permit of either nose or base fusing, or even the use of two fuses at the same time. This shell also provides a good example of the ballistic cap or false ogive.

Shrapnel Shell.—The shrapnel shell was invented in 1784 by Lieut. Henry Shrapnel, R.A., and was originally called the "spherical case shot." The idea of the inventor was to keep the bursting or opening charge as small as possible so that the velocity of the shell would be imparted to the bullets. After considerable delay this projectile was adopted by the British Government, and was apparently first used in action against the French, at the battle of Rolicca in 1808. In 1852 the British army adopted the name "shrapnel" in honour of its inventor. With the development of ordnance the design of this shell has been modified, but the principle involved remains the same. The body of a modern shrapnel shell is made with thin

walls, and it is closed either by a fuse socket or by a separate head, the part in either case being merely lightly attached. A fuse is screwed into the socket or head. The other parts of the shell are shown in the illustration. The bullets are made of heavy metal, but their weights vary with the size of shell. (See fig. 4.)

The central tube may or may not be provided with powder pellets. The action of the shell is simple. When the fuse functions a flash passes down the centre tube and ignites the opening charge, which pushes out the bullets and head.

A.P. Shell.—These shell are intended to penetrate armour and then burst effectively. The solid head is especially hardened and the walls are tough. They are generally fitted with caps to give an increased penetration. Old pattern shell may be filled with powder, but modern projectiles (fig. 5) are filled with H.E.

Special Shell.—Gas shell were introduced by the Germans during the World War, and were developed by them into weapons of great offensive power. Ordinarily shell bodies of H.E. design were utilized and filled with a liquid or solid substance which volatilized on exposure to the air, giving a concentration of gas sufficiently strong to disable an unprotected man. The shell were usually opened by a small charge of explosive, the fuse employed being of the instantaneous type. In later patterns of shell the chemical ingredients were inclosed in a bottle which was buried in an ordinary H.E. filling. The shell functioned as an ordinary H.E. shell with the additional deleterious effect due to the chemical.

Smoke shell are really another product of the World War. In

FIG. 1.—DIAGRAM OF COMMON POINTED SHELL

FIG. 2.—DIAGRAM OF MODERN BRITISH HIGH EXPLOSIVE SHELL

FIG. 3.—DIAGRAM OF MODERN GERMAN HIGH EXPLOSIVE SHELL

design they resemble gas shell and are filled with composition intended to give smoke clouds for purposes of concealment. They are actuated by direct action fuses and contain small H.E. opening charges. Incendiary shell, also introduced by the Germans, contain incendiary substances and are used with either

FIG. 4.—DIAGRAM OF MODERN SHRAPNEL SHELL

opens and keeps the star floating in mid-air until it burns out.

Cartridges.—Cartridges for ordnance are divided into two main classes, called breechloading or B.L. and quickfiring or Q.F., and each class is subdivided into gun and howitzer cartridges.

The terms B.L. and Q.F. are essentially British, but in other countries the two classes are distinguished by different names.

Propellents.—The actual propelling charges are smokeless propellents of the nitrocellulose type, with or without an admixture of nitroglycerine. They are somewhat difficult to ignite, and hence an igniter of gunpowder is usually embodied in the cartridge. The propellant may be manufactured in various forms, e.g., sticks or cords, tubes, flakes, and disks, the form and size providing a means of controlling the burning. Well known modern propellents of various forms are Cordite, Röhrenpulver, N.C.T., Ballistite, Ringpulver and Flake.

B.L. Cartridges.—B.L. cartridges for guns consist of cylindrical bundles of propellant enclosed in silk bags with shalloon disks

FIG. 5.—DIAGRAM OF ARMOUR PIERCING SHELL, USED IN ATTACKING ARMoured CARS AND AIRCRAFT IMPENETRABLE TO THE NORMAL BULLET

containing gunpowder stitched on to one or both ends. With heavy charges, the cartridge may be made up in part-charges and loops provided for lifting. For howitzers, the cartridges are made up in portions which allow varying charges to be used, and consist of a mushroom shaped core with rings or bundles of propellant attached by tape. (See fig. 7.)

Q.F. Cartridges.—The essential feature of these cartridges is the brass case which carries the propellant. With small guns the cartridge case is usually attached to the shell, but in heavier calibres the cartridge is a separate component. The use of the brass case in certain circumstances leads to rapidity of fire and simplification of breech mechanisms and it gives safety against

accidental ignition. On the other hand, brass is expensive in itself and adds to the weight of the cartridge, entailing increase in transport. Unsuccessful attempts have been made to introduce other metals, such as steel or aluminium. (See fig. 8.)

Means of Ignition.—B.L. cartridges are ignited by means of tubes. A tube in its simplest form is a brass cylinder containing a charge of fine grain powder, which is ignited by friction, by

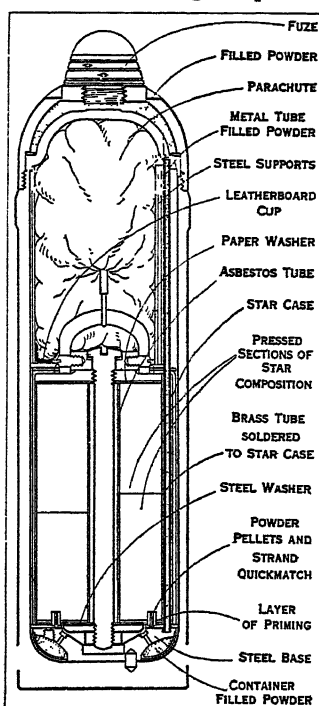

FIG. 6.—DIAGRAM OF SECTION OF A GERMAN 15 CM. STAR SHELL

fuses, combined (a) Combustion, (b) Mechanical or clockwork.

(1) (a) Direct action fuses function as a result of a direct blow on the nose, a hammer or needle being forced on to a detonator. A modern pattern of D.A. fuse is the British fuse No. 106 illustrated in fig. 11, from which its general construction will be understood. It is protected before loading by a safety cap, which is removed by hand. A split steel collar is interposed between the underside of the hammer head and the top face of the fuse body, and round this collar the safety tape is wound. On firing, the tape weight is gripped between the hammer head and body. When the shell leaves the bore the weight is released, flies off, unwinds, and carries the tape with it, tearing away the

FIG. 7.—DIAGRAM OF A BREECHLOADING GUN CARTRIDGE

split collar. The hammer is then supported only by a thin shearing wire. On impact, the hammer is driven in, shearing the copper wire, the detonator is fired, and in turn fires the magazine. A safety shutter is provided, which only opens after the shell leaves the bore of the gun. Another type of D.A. fuse, somewhat less sensitive than the ordinary type, is the direct action impact type (D.A.I.). Such fuses merely differ from ordinary D.A. type in that the suspension of the needle or hammer is very much stronger, and hence the fuse requires a stronger blow on the nose in order to make it function.

(b) Graze fuses or check action fuses function as a result of the forward movement of a graze pellet relatively to the main body of the fuse. When the shell receives a check in velocity a pellet carrying a detonator moves forward on to a fixed needle or alternatively a needle pellet moves on to a detonator. A typical nose graze fuse is illustrated in fig. 12. The illustration represents the German fuse Kz. f. Spgr. m. K., and shows its general construction. Before firing, the detonator pellet is kept away from the needle by five interlocking brass leaves held in position by a brass ferrule supported on a split brass sleeve. On firing, the ferrule sets back clear of the safety leaves and rebound is prevented by two lugs on the sleeve. When the shell leaves the bore, the brass leaves open out one by one under the influence of centrifugal force, leaving the fuse in a sensitive condition or "armed." Creep action of the detonator pellet during flight is prevented by the so-called creep spring. On graze, the pellet flies forward on to the needle and the detonator fires, the flash passing through a hole in the pellet to the exploder in the shell. A practice common in German design is to arrange a combination of direct and graze action effects in one fuze. In this type the detonator is housed in a movable pellet which functions in the usual way. The needle is formed on the inner end of a rod, the outer end of which projects from the top of the fuse. On impact, the detonator pellet moves forward on to the needle as in an ordinary graze fuse, but in addition to this action the needle is also forced on to the detonator by direct action.

(2) A time fuse is one which can be set to burst a shell at a certain predetermined time after firing. A time and percussion fuse, commonly known as a T and P fuse, embodies, in addition to the time mechanism, a graze percussion mechanism which will function independently should the shell strike any object in flight or on impact with a target. Time fuses are divided into two main classes, (a) burning or composition and (b) mechanical or clockwork. The modern composition fuse is exemplified by the British T and P No. 80. In this fuse the time is measured by the burning of a train of black powder which is compressed into annular grooves in adjustable rings. The firing of the gun initiates the burning of the rings and eventually the flash reaches the magazine and thence the opening charge of the shell. The movable ring type of time fuse is almost universal but a notable exception may be noted in French fuses of type No. 23-31, which is set by punching a hole at the appropriate point in a composition filled lead tube by a machine called a debouchoir. (See fig. 13.)

The use of burning composition in time fuses is by no means ideal, and for many years experiments have been carried out with a view to obtaining a clockwork or mechanical apparatus. Various patterns were tried but none was satisfactory until 1916, when the Germans brought into use a clockwork fuse Doppelzunder 16 (T and P fuse 1916 pattern) which may be considered as typical of this class. This fuse is illustrated in figs. 14 and 15, the illustrations being diagrammatic and the description which follows is of principle and arrangements only. The clock train is

FIG. 8.—A QUICKFIRING CARTRIDGE

driven, as in a watch, by a coiled spring in a barrel, but the escapement is original and peculiar. A straight steel spring takes the place of the hair-spring, which would be rendered useless by the effect of rotation and shock of discharge, and as the length of the straight spring is adjustable, the movement of the pallet, of the balance, and therefore that of the escapement wheel and the clock train, is controlled and regulated. A horizontal hand, the position of which depends on the setting of the fuse, has, on its under surface, a notch, into which fits the upturned end of the lever at the top of the striker. When the clock train is started the hand moves round with it, but is prevented from rising and releasing the lever by a ring attached to the conical housing of the fuse. This ring is provided with two slots into which the hand can fit; thus, when the clock is working, the rotation brings the hand into coincidence with the slots, and when forced up by the action of a small spring it releases the upturned end of the lever. The striker, previous to firing, has been held in the safe position by a collar on it, which rests on a shoulder of the centrifugal bolt, but when this bolt is moved away by the rotation of the shell the outer end of this shoulder still rests on a steel pin. When the upturned end of the lever is freed from the notch in the lower side of the hand, as previously described, it flies out and rotates the striker, so that the collar clears the steel pin and allows the striker to fall and fire the detonator. The setting of the fuse and the hand is accomplished by turning the housing with a suitable key, this housing being free to move before firing. On discharge it is very ingeniously clamped to the body of the fuse by means of steel pins in a ring in its under surface. This ring sets back and the pins are driven through the flange of the clock case, a groove being turned on its under side to thin the metal and thus to allow of easy penetration. The clock train, wound up like a watch, is started at the moment of firing by the setting back of a detent.

II. AMMUNITION FOR OTHER WEAPONS HISTORICAL

Small arm ammunition is used with rifles, machine-guns, revolvers and pistols. Its early history is closely allied to that of

ammunition for ordnance, but as early as 1586 a composite cartridge was used by musketeers, consisting of a bullet and powder charge wrapped in paper. The paper was torn or bitten, the powder poured into the barrel, and the bullet and paper rammed home. The means of ignition were devices such as matchlocks, wheel locks and flint locks, which ignited powder primers. The early bullet was a spherical leaden ball. Primitive cartridges were

FIG. 10.—DIAGRAM OF A PERCUSSION PRIMER

FIG. 9.—DIAGRAM OF A PERCUSSION TUBE

used by Gustavus Adolphus in 1625, and later are found in England with S.B. (smooth bore) muskets, their use persisting up to the time of the Crimea.

Rifled small arms were known in the 15th century and were used by the Danes in 1611, Bavarians 1640 and by the French in 1742. At about this last date the use of the rifle was becoming more general and the ammunition was similar to that of the S.B. musket. The excellent use of the rifle made by the American colonists in the War of Independence expedited its introduction into the British and Continental armies. The problems with this early ammunition were the prevention of windage and fouling and to make the ball take the rifling. By 1800 rifles were in general use and the development in ammunition was accelerated by the invention of "percussion powder" and "percussion caps." In 1826 Delvigne devised a system of distorting the

BY COURTESY OF THE UNITED STATES WAR DEPARTMENT

MANUFACTURING AND STORING HIGH EXPLOSIVE SHELLS

1. A hot shell casting being lifted out of the mould. Molten steel is poured from cupola to mould, the rough casting is then lifted out and transported by special mechanical equipment to finishing room
2. Finishing the shell. The shell after being cast is set up in specially equipped lathes and machined with great accuracy by high-speed tools
3. The loading counter, showing the finished shells ready to be loaded with high explosives, TNT. (trinitrotoluene), or chemicals
4. Caps being placed in position and explosives being poured into shells
5. The filled shells ready for shipment, in the shell store, a building for this purpose under special regulations
6. An ammunition dump. The shells are stored on battens and covered with tarpaulins, which are removed whenever conditions are favourable, to permit ventilation and to prevent "sweating." The shells are never exposed to the direct rays of the sun

bullet by ramming, to make it take the rifling, but this led to inaccuracy. In 1833 Poncharra improved the Delvigne system by introducing a "sabot" below the bullet. He also used greased paper for lubrication.

In 1835 Greener introduced an expanding oval bullet, fitted with a metallic tapered plug in its base. In 1837 the Brunswick bullet was introduced. It was spherical and had a belt to fit the

FIG. 11.—DIAGRAM OF A PERCUSSION DIRECT ACTION FUSE

Brunswick rifling. In 1848 the Minié rifle was devised, firing a bullet similar to the Greener, but it had an iron cup in the base instead of a plug. In the meantime a percussion lock for firearms was becoming universal, but the development of the cartridge was slow. The Minié system persisted for many years and other devices, such as Pritchett's bullet, were tried, all with the object of getting rotation. At about the same time as the invention of the Minié the Prussian needle gun (invented by Dreyse in 1838) was adopted by the Prussian army. It had an elongated oval bullet which fitted into a cup-shaped wad containing a percussion cap. The charge was in a paper cylinder, which was tied to the bullet over the cap. The obturation was bad, but the system was a great advance in rapidity of fire.

In 1855 the cup in bullets of the Minié type was replaced by a boxwood plug, and eventually the boxwood was itself superseded by a clay plug. In 1854 Whitworth invented the hexagonal bullet for use in his rifle. It was successful but was unsuitable for S.A. (small arm) requirements. Fouling and loading difficulties persisted. In 1865 Metford demonstrated the advantages of the hardened bullet, which made shallow grooves permissible and reduced fouling. In 1867 breech-loading rifles and brass cartridge cases were coming into general use, owing to the great success of the needle gun in 1866. In 1866 the brass cartridge case of the Boxer type was introduced. It was formed of rolled brass strip and attached to the bullet by a cemented paper joint. The lower end fitted into a brass cup fitted with a cap. Cannelures filled with beeswax provided lubrication. In about 1880 solid drawn cases were suggested and shortly afterwards introduced. In 1883 Rubin designed a composite bullet which was made of lead, with a copper jacket, and in 1887 cupro-nickel was introduced for jackets in certain armies. About this time the introduction of smokeless propellants of the modern type led to great developments in S.A.A. (small arm ammunition). In 1886 nitro-cellulose powder was invented by Vieille and adopted by the United States, France and other nations. In 1891 cordite was adopted by Great Britain. The further development of S.A.A. becomes a matter of modern technical history.

TECHNICAL

A round of small arm ammunition, commonly called a cartridge, consists of (a) a cartridge case, (b) percussion cap, (c) propellant charge and (d) a bullet. For all S.A.A. certain standards of accuracy and range are necessary, and erosion, wear, metallic fouling, and hang fires should be eliminated.

Parts of the Cartridge.—(a) The cartridge case is made of solid drawn brass and is shaped to suit the chamber of the weapon. The front of the case is soft, to allow for the necessary expansion for gas sealing purposes, whereas the rear end is hard to give the necessary strength for extraction. A flange or groove is

provided at the base to facilitate the extraction of the empty case. A small chamber is formed at the base to house the cap, and fire holes are provided for the ignition flash.

(b) The percussion cap is made of brass or copper and fits accurately into the recess in the base of the cartridge case. It is secured by pressing over the metal of the case. The cap is filled with suitable composition which is readily fired by percussion. Owing to a tendency to deterioration of the composition under warm and damp conditions, the modern practice is to overload the cap and protect it by varnishing or other means.

(c) The propellant charge may be either nitro-cellulose powder, which is the custom in the United States of America, or one containing a proportion of nitro-glycerine as in British cordite. It is claimed for nitro-cellulose that it gives the same velocities with lower maximum pressures, but it is more susceptible to dampness.

(d) A good bullet should be symmetrical in shape and mass. The modern rifle bullet consists of an envelope and core, the envelope being made of a fairly soft alloy and the core of lead. Cupro-nickel and soft steel have been used for envelopes generally, but in America an alloy of 90% copper has been tried with success. The shape of the rifle bullet is important in obtaining a long range and the necessary accuracy. For this reason modern rifle bullets are provided with sharp points struck with circles of radius equal to 8 times the calibre. Stream-lining or boat-tailing the bases of rifle bullets will also give increased range; but this practice has not been universally adopted, owing, probably, to difficulties of manufacture and possible inaccuracy of shooting. Machine-gun ammunition is similar to rifle ammunition and is ordinarily interchangeable.

Special Bullets.—A tracer bullet was introduced during the World War, for rifles and machine-guns. The base was stemmed with a burning composition, which was ignited by the propellant gases, and hence the bullet left a visible wake of smoke or flame. Armour piercing bullets have also been introduced to attack

FIG. 12.—DIAGRAM OF CONSTRUCTIONAL PARTS OF A PERCUSSION GRAZE FUSE

armoured cars, aircraft and similar targets which defeat the normal service bullet. They are jacketed with harder envelopes and have a core of specially treated steel, the space between the core and envelope being filled with a lead surround. These bullets can be fired from an ordinary service rifle and will penetrate about 0.25in. of armour. A further modification of this bullet of 0.5in. calibre can be fired from specially constructed weapons and will penetrate nearly 1.00in. of armour.

Pistol Ammunition.—In the British army the 0.455in. calibre revolver, with its heavy, unjacketed lead-antimony bullet,

has remained unchanged for 30 years. As a man-stopping projectile at point blank range it remains unbeaten, but its weight and poor accuracy at longer ranges limit its value. Most nations have adopted automatic pistols for their subsidiary weapon, and for these, jacketed bullets, either of copper or cupro-nickel, are employed. The various nations differ as to optimum calibre for pistol ammunition, but the tendency appears to be away from the light comparatively high-velocity bullet, such as the German

FIG. 13.—DIAGRAM OF THE CONSTRUCTIONAL PARTS OF A TIME AND PERCUSSION FUSE

o.300 Mauser, which was sighted up to 1,000yd., thus holding the pistol to its true rôle, namely, that of a man-stopping weapon at short range.

Aeroplane Bombs.—The aeroplane bomb was developed in the World War and became an important offensive weapon. The main difference between aeroplane bombs and gun projectiles is one of strength. The latter may have to attain a muzzle velocity of about 2,000ft. per sec. in the length of the piece, and this entails pressures running up to 20 tons to the square inch. The former is merely dropped, so that the stresses on it when falling are very little greater than those encountered in normal handling and transport, and it is only when penetration of concrete buildings or armoured decks is sought that anything more than a thin steel case is required to contain the H.E. filling. As regards shape, the terminal velocity of an aeroplane bomb is never above 1,100 ft. per sec., hence the stream-lining of the tail is just as important as the contouring of the head. Most bombs are therefore pear-shaped, with vanes attached to the cone of the tail to ensure that the bomb drops nose first.

Method of Detonation.—To initiate the detonation of the H.E. filling on impact with the target, fuses or similar devices are used. These are usually simple mechanisms depending for their arming on the unscrewing of vanes by the air stream whilst falling. In general a safety pin, which is only withdrawn from the fuse when the airman drops the bomb, is used as an additional safety precaution. The building up of the detonation wave is accomplished by a central exploder, which may run the whole length of the bomb or, as in gun shell, only a few inches into the H.E. filling. (C. W. F.)

THE UNITED STATES

A round of ammunition for a gun, in the United States, consists of a cannon primer, a propelling charge with its container, a projectile and a fuse.

ARTILLERY AMMUNITION

Types of Projectiles.—Two general types of projectiles are used for field, siege and coast artillery known as shell and shrapnel. Shell are made of steel and are filled with low explosives (black powder), high explosives (TNT) or chemicals. Low explosive shell produce fragments upon explosion; high explosive shell, blast effect and fragments; and chemical shell, gas or smoke cloud effect. Other types such as star or illuminating shell are

used for special purposes. Artillery shell are made in sizes from slightly over one inch in diameter, weighing about one pound to 16 inches in diameter, weighing over a ton. Shrapnel are filled with a number of balls and when the time fuse, with which a shrapnel is fitted, functions, the powder charge of the shrapnel is exploded. The balls are expelled forward in the form of a cone, with action similar to that of a shot gun. Shrapnel are usually used only in field and anti-aircraft guns.

Fuses.—Fuses are used in practically all service projectiles, to detonate, ignite or scatter the bursting charge of the projectile at the time and under the circumstances desired. Point fuses are usually used in high explosive and chemical shell to obtain quick action and burst the shell before it has penetrated the ground. Base fuses are in general used in projectiles for penetrating hard substances, such as armour plate, concrete, etc., where a point fuse would crush and fail on impact. Most fuses used in shell function upon impact, while fuses used in shrapnel and anti-aircraft shell are of the time type, which are designed to function at some pre-determined time after the projectile leaves the gun and during the flight of the projectile. The time fuse used in shrapnel intended for ground targets is designed also to function upon impact. The time interval in most time fuses is obtained by means of the burning of a powder train, the length of which is varied by the setting of the fuse. A mechanical time fuse is one in which the desired time interval is obtained through a mechanical device rather than the burning of powder.

High Explosives and Bursting Charges.—The principal high explosives used are trinitrotoluene (TNT), picric acid, ammonium picrate and amatol, a mixture of trinitrotoluene and ammonium nitrate. In the case of shrapnel, however, where balls are ejected from a case, this shattering effect is not desired, and a "low explosive," such as black powder, is therefore used. In this case the time required for the explosion to be completed is relatively large as compared to the time for detonating explosives, and the heated gases, being developed more slowly, do not exercise such a

FIG. 14.—DIAGRAM ILLUSTRATING ACTION OF MECHANICAL TIME FUSE
disruptive effect. In the case of "high explosives," such as T.N.T., detonation is initiated by means of some highly sensitive detonating agent such as mercury fulminate in the fuse. In the case of "low explosives," however, explosion is brought about by means of simple ignition.

Propelling Charges and Cases.—The propelling charge, usually of smokeless powder (nitrocellulose, cordite, etc.), in the case of the smaller calibres of ammunition, is contained in a brass case, known as a cartridge case, which has a primer in the base to ignite the smokeless powder, and is crimped to the base of the

projectile. This type of ammunition is known as "fixed ammunition," and is usually in calibres from 37mm. to 4.7 inches. In the case of "semi-fixed ammunition," the cartridge case is not crimped to the projectile. This type is used with howitzers where the powder charge is in the form of zoned bags within the cartridge case, and where it is necessary to adjust the weight of charge for different ranges. In the larger calibres of guns, where the projec-

FIG. 15.—TIME AND PERCUSSION MECHANICAL CLOCKWORK FUSE

tile is heavy, it would be impractical to use a complete round. The projectile, propelling charge and primer, therefore, are issued separately. In loading the gun, the projectile is first rammed to its seat and then the propelling charge is inserted. The propelling charge in "separate loading ammunition" consists of smokeless powder in one or more bags. Raw silk is used for these bags as this material is practically entirely consumed by the combustion of the smokeless powder, and leaves no smoldering fragments. In this way the danger of igniting the next propelling charge before the breech block of the gun is closed is avoided. In the case of guns, the propelling charge may be in one section or several, depending upon the weight of the complete charge. For example, since the weight of a charge for the 16-inch gun may be as much as 800lb., the charge is divided into four or six sections for ease of handling. In the case of the large calibre mortars, where various weights of charge are used to obtain various ranges, the total charge is zoned; i.e., divided into several bags.

Primers and Igniters.—The primer, used to ignite the propelling charge of smokeless powder, is a small brass case loaded with a charge of black powder, which, in the case of the smaller calibres, is sufficient to produce efficient ignition of the propelling charge. The primer has in its head a small percussion cap which is struck by the firing pin of the gun, thus igniting the black powder charge, which in turn ignites the propelling charge. In the case of the smaller calibres, where cartridge cases are used, the primer is assembled in the head of the cartridge case. With larger calibres, the primer is assembled in the breech mechanism of the gun. With larger calibres additional igniting powder (black powder) also is required. This is usually made up in the form of a bag attached to the rear of the propelling charge. In some of the largest calibres this additional igniter may extend through the core or centre of the propelling charge. The size of this igniter increases with the calibre of the gun. In the case of the 16in. gun an igniter of 6lb. may be used.

III. SMALL ARMS AMMUNITION

Ammunition for Small Arms.—In America military small arms ammunition for rifles consists of a cartridge composed of a bottle-necked, rimless cartridge case containing a non-corrosive primer, a charge of nitrocellulose smokeless powder, and a conical, sharp pointed bullet having a core of lead and a jacket composed of copper and zinc. For revolvers and pistols the bullet is not always jacketed, but may be composed of an alloy of lead, tin and antimony. For rifles, five cartridges are usually secured to-

gether at the head of the cases by means of a clip, thus permitting all five cartridges to be inserted in the magazine of the rifle in one motion. Small arms cartridges are usually packed in cardboard cartons of 20 to 50 rounds, or in cloth bandoliers of 60 rounds for convenient issue, and these cartons or bandoliers are in turn packed in wood boxes of 1,000 to 2,000 rounds for transportation purposes.

Primers.—The primer, inserted in a cup at the rear end of the cartridge case, serves to ignite the primer and contains the priming mixture. Formerly priming mixtures all contained a large percentage of potassium chlorate, but it has recently been found that this was almost the sole cause for the serious corrosion in the bores of small arms. The most recent development in primers in the United States has been the complete elimination of potassium chlorate from the priming mixture, thus making the ammunition non-corrosive.

Powders.—Formerly all reliable smokeless powders were of the nitroglycerine type. While such powders have been greatly improved, the greatest advancement has been in the development and perfection of nitrocellulose powders to the point where they can now be considered the equal of any nitroglycerine powders in reliability, while having very great advantages in the matter of lessened erosion. Improved nitrocellulose powders have more than doubled the life of the barrels of small arms.

Bullets.—Prior to 1906 bullets for small bore military rifles were cylindrical, with a rounded nose or point. The bullets for the .30 calibre U.S. rifles of the models of 1892 to 1903 weighed 220 grains, being composed of a lead core with a jacket of cupro-nickel. In 1906 the bullet was decreased in weight to 150 grains and the point was changed to a sharp form. The sharp point greatly lessened the air resistance, and the lighter weight permitted more powder to be used, thus greatly increasing the velocity (2,250 f.s. to 2,700 f.s.), and flattening the trajectory. In 1926 a still further improvement was made in this bullet, the weight being increased to 172 grains and the form changed to a boat-tailed or streamline shape. With the same initial velocity as previously, this change in weight and form increased the maximum range of the rifle and its cartridge from 3,300yd. to 5,600yd., and very greatly increased the range to which the sheaf of fire from machine-guns could be effectively controlled. At the same time the material of the bullet jacket was changed from cupro-nickel to a composition of copper 90 parts, zinc 10 parts, the change doing away entirely with the metal fouling of the bores of small arms which had always been troublesome with bullets jacketed with cupro-nickel.

Sporting Small Arms Ammunition.—Improvements in sporting cartridges for rifles have paralleled the military cartridges in details. Black powder cartridges and those with heavy bullets are now obsolete. Modern cartridges are of the ultra high velocity type, employing light bullets at muzzle velocities from 2,300 to 3,500ft. per second. The bullets are made to expand on impact by leaving a portion of the lead core exposed at the point or by a hollow point. The continent of North America does not contain any dangerous or thick-skinned game, and hence in the United States there has been little or no development of the extremely powerful sporting cartridge, such as is needed for the heavy game of Africa and southern Asia. Instead, developments have tended towards greatly increased accuracy and very flat trajectory. Most sporting rifle cartridges now employ bullets jacketed with an alloy of copper and zinc to avoid metallic fouling, and the non-corrosive primer has become quite general in its application.

In ammunition for shotguns a progressively burning, nitrocellulose powder has quite generally been adopted for the better grades of cartridges. This new powder has enabled the velocity to be increased several hundred feet per second, with little increase in the breech pressure, and with no bad effect on the patterns.

AEROPLANE BOMBS

Types of Bombs.—Bombs are of two main types, *explosive* and *chemical bombs*. The *explosive bombs* are further subdivided into *demolition* and *fragmentation bombs*. The *demolition* bombs

are intended for destruction of enemy works and depend primarily upon blast or shock effect for the destruction of these structures. The destructive effect is the result of the detonation of the high explosive content of the bombs, which is usually TNT. The explosive charge constitutes approximately 50% of the total weight of bombs. The largest size of demolition bomb ever manufactured is one weighing 4,000 pounds. Most of the bombs are streamline in shape. The present tendency in design is towards bombs which have a cylindrical body and a nose in the form of a modified ellipse either secured to or integral with the cylindrical portion. *Fragmentation* bombs are intended for use against personnel. They depend upon the fragmentation of the metal case at or above the surface of the ground to produce casualties. These bombs are much smaller than the demolition bombs, the largest weight of bomb being approximately 50 pounds. They are filled with about 15% of TNT. The main type of *chemical* bomb is the smoke bomb. These bombs are intended for use as obscuring agents. At present the formation of smoke screens is employed to mask known enemy observation posts, to conceal and protect the front flanks of attacking troops from enemy observation and to blind hostile machine-guns. Titanium tetrachloride and white phosphorus are the two chief chemicals used as smoke producing agents.

Bomb Fuses.—Demolition bombs are usually equipped with both nose and tail fuses, while fragmentation bombs and chemical bombs are equipped with nose fuses only. The fuses are of two types, the *arming vane type* and *arming pin type*. When assembled to the bomb, prior to the release of the bomb from the plane, the fuses are usually in an unarmed condition, that is, mechanical restraints prevent the fuses from firing the primer or detonator which initiates the detonation. In the case of the arming pin type of fuse these mechanical restraints are removed immediately upon release from the plane, while in the case of the arming vane type of fuse all the mechanical restraints are removed only after the arming vanes have made a definite number of revolutions due to the action of the air and the bomb has fallen a considerable distance from the aeroplane. Upon impact the firing pin of the fuse fires the primer or detonator which initiates the detonation. Where it is not desired that the bombs detonate, they are released so that the mechanical restraints within the fuses will not be removed. On impact the firing pin of the fuse is thus prevented from coming into contact with either the primer or detonator which in turn prevents detonation of the bomb. Fragmentation and chemical bombs are equipped with detonators which permit them to function instantaneously upon impact, while demolition bombs are equipped with detonators which permit of either instantaneous or delay functioning after impact.

AMMUNITION SHIPS: see FLEET AUXILIARY VESSELS.

AMNESIA, a term used in psychopathology for functional disturbances of memory (Gr. *ἀμνησία*, forgetfulness). An amnesia may be *general*, in which case all functions of memory are involved, or *partial*, in which case only certain groups of ideas, proper names, the meanings of words, special events and their associations, and the like, are screened from memory. (See HYPNOSIS.)

AMNESTY, an act of grace by which the supreme power in a State restores those who may have been guilty of any offence against it to the position of innocent persons. It includes more than pardon, inasmuch as it obliterates all legal remembrance of the offence. Amnesties, which may be granted by the Crown alone, or by act of parliament, were formerly usual on coronations and similar occasions, but are chiefly exercised towards associations of political criminals, and are sometimes granted absolutely, though more frequently there are certain specified exceptions. Thus, in the case of the earliest recorded amnesty, that of Thersybulus at Athens, the 30 tyrants and a few others were expressly excluded from its operation; and the amnesty proclaimed on the

restoration of Charles II. did not extend to those who had taken part in the execution of his father. Other celebrated amnesties are that proclaimed by Napoleon on March 13 1815, from which 13 eminent persons, including Talleyrand, were excepted; the Prussian amnesty of Aug. 10 1840; the general amnesty proclaimed by the emperor Francis Joseph of Austria in 1857; the general amnesty granted by President Johnson after the Civil War in 1868; and the French amnesty of 1905. The last act of amnesty passed in Great Britain was that of 1747, which proclaimed a pardon to those who had taken part in the second Jacobite rebellion.

An amnesty clause is usually inserted in peace treaties granting immunity from prosecution for acts committed contrary to laws and customs of war by members of the armed forces of the respective belligerents or by their subjects. Not infrequently, however, named persons or persons alleged to have committed war crimes, subjects of the defeated belligerent, are excepted from the amnesty clause and a stipulation for their surrender is expressly included in the treaty. Instances of such exceptions are the Treaty of Peace with the Boers in 1881, the Vereeniging Treaty of 1902, and the Peace Treaties between the Allies and Associated Powers and Germany and her allies after the World War. A belligerent may, however, punish his own subjects, unless the contrary is stipulated in the treaty of peace. For instance, Russia in 1878 stipulated that Turkey should grant an amnesty to such of her own subjects as had compromised themselves during the war. (H. H. L. B.)

AMNIOTA, a term sometimes used in zoology to denote collectively the reptiles, birds and mammals. The word refers to

the presence in all three groups of a membrane, the amnion, round the developing young and enclosing a fluid-filled space. (See VERTEBRATE EMBRYOLOGY.)

AMOEBAS, the name given to certain microscopic animals (see PROTOZOA) which creep along and engulf their prey by outthrust and retraction of *pseudopodia*, or lobose processes of the naked undivided protoplasmic mass of which their bodies are composed (see PSEUDOPodium). These animalcules are found in fresh water and in the sea, and many live on or in the bodies of other animals, both invertebrate and vertebrate; man himself may harbour six different species in his alimentary canal. The first account of an amoeba was that by Roesel, who in 1755 gave a graphic description of the flowing movements and consequent change of shape in the "proteus" as he called it. The same kind of movement is shown by certain cells of the metazoan body; for instance, by developing eggs of sponges and by the white corpuscles of the blood of many animals. The myxomycetes, some of the flagellates and certain of the sporozoa also have amoeboid stages in their life - history. Bütschli regarded amoeboid movement as a physical phenomenon due to alterations in the surface tension, and he showed that "artificial amoebae" consisting of drops of oil-soap emulsion, creep about actively for several days by pseudopodia. Verworn and others then demonstrated that the type of pseudopodium formed by an amoeba can be changed by increasing the alkalinity of the surrounding medium.

FROM F. V. HAYDEN "FRESHWATER RHIZOPODS," REPORT OF THE U.S. GEOLOGICAL SURVEY

AMOEBAS INHABITING FRESH WATER
This unsymmetrical shape is one of many that the amoeba can assume. It has no mouth but takes in and discharges food from any part of its body. The circle and dots on the lower right are food particles being ejected in this way. (The line along the left side represents 1/2 mm.)

Pelomyxa, which is a giant of the group, measures as much as 3mm. But the majority of amoebae are not visible to the naked eye, and the small forms that develop in the surface film on an organic infusion measure only about .001mm.

Where it comes in contact with the surrounding fluid, the protoplasm of an amoeba is usually clear and comparatively firm: this layer is the "ectoplasm." The interior "endoplasm" is more fluid and very often granular; the streaming movements that accompany pseudopodium formation can be followed by watching the circulation of these granules. There is no mouth or anus; food is taken in and the undigested remains cast out at any point on the surface. Amoebae living in ponds or in gently running streams feed on algae, diatoms, and other protozoa; the amoebae in organic infusions devour bacteria, and the same is true of the endoparasites, which are probably really harmless scavengers. *Entamoeba histolytica*, however, which is known to be the causal organism of a form of dysentery in man, devours red blood corpuscles. The amoebae and associated flagellates living in damp earth are believed to exert a considerable influence on the bacterial content and consequent fertility of the upper layers of the soil.

Each simple protoplasmic mass constituting an amoeba contains a nucleus, usually with a central karyosome and peripheral chromatin, and when the full-grown body divides by binary fission, which is the normal mode of multiplication, the nucleus divides also. This nuclear division involves a scrupulous distribution of the chromatin to the two daughter individuals; there is, in fact, a modified mitosis (*q.v.*). In certain cases it has been shown that repeated division of nucleus and cytoplasm within a "cyst" gives rise to a new brood. As yet, no sexual phase has been clearly demonstrated in any true amoeba. A constant feature of all fresh-water amoebae is the fluid-filled "contractile vacuole" (*q.v.*), which opens to the surface by a pore and is often regarded as conveying nitrogenous waste to the exterior; the absence of this structure in marine and endoparasitic species suggests that it may also be concerned with regulating osmotic pressure.

The delicate bodies of amoebae are liable to rapid desiccation when exposed to air. They can tide over these periods of danger by adopting a spherical form and surrounding themselves with a protective envelope or cyst. Such cysts may be dispersed by air-currents or through the agency of insects such as flies, and if they fall into a suitable environment, the envelope ruptures and the contained amoeba emerges.

Most known species of amoeba can now be cultivated in the laboratory, the bacteria-loving forms on special agar media; and recently certain of the parasitic forms, even those like *Entamoeba histolytica* from a warm-blooded host, have been successfully grown *in vitro*. (D. L. M.)

AMOK, RUNNING: see AMUCK, RUNNING.

AMON, the human-headed god of Thebes, was probably a local variety of the ancient god Min of Coptos. The temple of Karnak was his home; it was called "the Thrones of the Two Lands" (*Nesut-toui*). He had also a temple of later foundation in southern Epet (Luxor).

AMONTILLADO, one of the two chief types of sherry wine exported. It is sweet and full-bodied, and derives its name from the town of Montilla in southern Spain (see **SHERRY**).

AMONTONS, GUILLAUME (1663-1705), French physicist, was born in Paris Aug. 31 1663, and died there Oct. 11 1705.

In 1687 he presented to the Academy of Sciences an hygrometer of his own invention, and in 1695 he published his only book. *Remarques et expériences physiques sur la construction d'une nouvelle clepsydre, sur les baromètres, les thermomètres et les hygromètres*. In 1699 he published some investigations on friction, and in 1702 and 1703 two noteworthy papers on thermometry. (See **COLD**.)

AMORA: see TALMUD; GAON.

AMORETTI, little loves, cupids. The title of a sequence of sonnets (published 1595), written by Edmund Spenser (*q.v.*) and dedicated to Elizabeth, probably the daughter of James Boyle, whom he married in 1594. The verses record the course of his wooing and close with the beautiful ode or *Epithalamion* celebrating his wedding.

See Emile Legouis, *Spenser*, chap. iv. (1926).

AMORITES. The Amorites are known from the Bible (together with the Jebusites, Hivites, etc.), as a pre-Israelite people in Canaan, and also as the inhabitants of two trans-Jordan kingdoms (Num. xxi.). The later Israelites believed that this primitive race was one of giants (Amos ii. 9; Deut. iii. 11).

The non-biblical material has markedly increased our knowledge and has also complicated it. Egyptian illustrations of the New Kingdom show the Palestinian Amorites to have been a race much more like the northern Europeans than the Semites; long headed, with blue eyes, straight nose and thin lips. Even the royal name *Akvāruvash*, the reputed contemporary of the ancient king Nārām-Sin of Akkad (about 2530 B.C.), in the Hittite copy of an inscription of the latter, seems to be Aryan or Indo-European (*cf.* Forrer, *Die Boghaz-köi-Texte in Umschrift*, II. 1, no. 3, col. 1, line 12.) The mixture of races, however, which went on from the earliest times in Canaan and over a considerable area of the surrounding countries must be taken into account.

Another impression is gained from the Babylonian material of the earliest period, where "west" (as one of the quarters of the heavens) and "the land of the Amorites" (*Amurru*, ideogr. *Mar-tu*) were of identical meaning. The Amorites were inhabitants of a territory lying west of Babylonia, and the majority of them belonged (as forerunners of the Aramaeans) to the western Semitic race.

The motherland of these peoples was the region of the Middle Euphrates: Khana (near the modern Tell-Ishāra, south of the mouth of the Khabur), Mari (near the extensive ruin-mounds Werdi and El-Erzi), Shukhi (between the modern 'Ana and Hit), Subir-Subartu (the modern El-Jezireh, as far as the Tigris) and Naharina (the north-western part of El-Jezireh, near the old Harrān). According to the old king list a dynasty from Mari had actually reigned over Babylon about 2900 B.C., and the names and statues of old kings of the Sumerian period of the kingdom of Mari have been recovered. But the identification of this Mari with the old capital of the Amorites is still uncertain.

The Amorites were gradually driven out of their mother-territory by an invasion of the Kharri and Mittanni from the north. In Babylonia they settled at first in their own villages and townships (*e.g.*, in Sippar) as merchants and as mercenary soldiers; but they soon began to reach out after sovereignty. About 2057 B.C. (according to Thureau-Dangin about 2105 B.C.) Sumu-abum founded the Amorite kingdom of Babylon. Hammurabi, his fifth successor, through his victory over the king Rim-Sin of Larsa, united the whole of Babylonia under his sway (1925 B.C.). This period of the Amorite dynasty meant for Babylonia the richest flowering of her culture. None the less, after 300 years, the Amorite kingdom in Babylonia fell before an invasion of the Hittites (under King Murshilish I., 1758 B.C.).

Meanwhile the Amorites had settled in the west of Lebanon and in the mountainous parts of Canaan, and perhaps even ruled Egypt for a short time. It is, in fact, probable that the foreign domination of Egypt, the so-called Hyksos (*c.* 1800-1580 B.C.), is connected with the wanderings of this Amorite people. This period was that of the Amorites' greatest power; what they lost in Babylonia was won in Egypt, Canaan and Syria. But after the downfall of the Hyksos kingdom the Amorites were in their turn subjugated by the native Egyptian Pharaohs of the 18th dynasty,

FROM G. DOBELL, "THE AMOEBA LIVING IN MAN." BY PERMISSION OF JOHN BALE SONS & DANIELSSON, LTD.

A SPECIES OF AMOEBA THAT SOMETIMES INHABITS THE HUMAN SYSTEM AND IS RESPONSIBLE FOR A FORM OF DYSENTERY. THE THREE CIRCLES ARE BLOOD CORPUSCLES (The line below the figure represents 1/100 mm.)

especially by Thutmose III. Only in Lebanon were they able to maintain what seems to have been a small Amorite kingdom, first under Egyptian and then under Hittite overlordship. The capital of this kingdom was probably Kadesh in Orontes, the modern Tell Nebi Mendi which is situated in the plain south of Homs (Emesa). From the Tell el-Amarna and Boghaz-keui cuneiform inscriptions we can follow the history of this kingdom for some 200 years (1400-1200 B.C.); we know, for instance, that under the rulers Abd-ashirta, Aziru and their successors, it extended its sway for a time to the rich Phoenician seaports. The trans-Jordan kingdoms of the monarchs Sihon and Og (Num. xxi.) must have been the final offshoots of the great Amorite kingdom.

The importance and influence of the Amorites were overrated by the late Professor A. T. Clay of Philadelphia; though his is the merit of having drawn attention to their importance. On the other hand, Bauer's careful researches have led him to an underestimation. According to him, *Amurru*, meaning the land to the west, or "the west," is a geographical term; the mercenary soldiers who dominated Babylon under the "dynasty of Amurru" were from a hill country of that name, lying, however, to the north-east; and the Amorite kingdom in the Lebanon and Orontes districts should be wholly separated from both of these. Thus the geographical and historical relations remain unintelligible.

There is a rich but scattered abundance of material on the language of the Amorites in the proper names and in the name-lists from the time of the first Babylonian dynasty, in the foreign words and proper names to be found in Egyptian texts, and, above all, in the foreign words and glosses of the El-Amarna letters. From this it is seen that the language represents an earlier stage of the Hebrew language (*q.v.*).

Lang.*, 41 (1925), pp. 282 sqq., concerning *Mari*. For the language see Böhl, *Die Sprache der Amarnabriefe* (1909); M. Burchardt, *Die altkanaanäischen Fremdwörter und Eigennamen im Aegyptischen* (1910); Chiera, *Lists of Personal Names*, Univ. of Penn., Univ. Mus., Babyl. Sect., vol. xi., nos. 2 and 3 (1916, 1919). (F. M. T. B.)

AMOROSO (Ital.), a musical term signifying that the passage so marked is to be played in an amorous style, that is, with warmth and tenderness; *con amore* has the same meaning.

AMORPHISM is a term derived from *a*, privative, and *μορφή*, form, and is used in chemistry and mineralogy to denote the absence of regular or crystalline structure in a body; the adjective "amorphous," formless or of irregular shape, is used technically in the foregoing sciences and also in biology, etc.

AMORTISEMENT: see AMORTIZATION.

AMORTIZATION, the paying off of a debt or obligation, or the extinguishment of an asset by means of a series of partial payments or charges, prorated to extend over the period during which the obligation or asset will exist. Such amortization payments are usually in annual or semi-annual amounts, each of which is sufficient to cover the interest, if any, and also to provide for a certain reduction of the principal.

The amortization principle is used in finance for the purpose of obliterating the premium or discount on bonds which are bought or sold above or below their par value. As bonds approach their maturity date, at which time they will be paid off at par, their carrying value approaches their par value, actually reaching it at the time of redemption. If such bonds have been bought or sold at a premium or at a discount then such premium or discount must be amortized by the time of maturity in order to bring these two values to a point of coincidence in the accounts. If a bond is bought above par, at a premium, and repaid at par, the owner loses an amount equal to the premium; if it is bought below par, at a discount, and redeemed at par, the owner gains an amount equal to the discount. If the bond is sold above par, at a premium, and redeemed at par, the issuer gains an amount equal to the premium; if it is sold below par, at a discount, and redeemed at par, the issuer loses an amount equal to the discount.

This premium or discount which is gained or lost as the case may be, should be amortized over the life of the bond by periodic charges or credits.

The amortization of bond discount by the issuers will work out as follows. A thousand dollar 5% bond is sold at 80% of its face value. This increases the company's liabilities by \$1,000 and increases its assets by the amount of cash realized, \$800. The difference of \$200 is the bond discount and is entered under this name as an asset. This is, of course, only a balancing item or practically a dummy asset, and if the company is to make its real assets equal to its increased liabilities it must add to its property an amount equal to \$200. The most usual way is to lay aside from earnings annually a predetermined sum either fixed (approximate method) or varying (scientific method), which over the life of the bond will amount to the discount of \$200. Amortization of premiums may be accomplished in a similar manner.

AMORY, THOMAS (c. 1691-1788), British author, published *Memoirs; containing the lives of several Ladies of Great Britain; a History of Antiquities, etc.* (1755) and *Life of John Bunce Esq.* (1756 and 1766). Both books are an extraordinary mixture of fiction, autobiography, scenic description and theological discussion. Of the two *John Bunce* is by far the more readable. "The hero," says George Saintsbury, "becomes less nebulous; in fact he is, at least, of the world of Dickens, when he sits down, in the highest state of contentment, and, in fact, of positive carol, to a pound of steak, a quart of peas, another (or several others) of strong ale and divers cuts of fine bread." "The soul of Rabelais," says Hazlitt, "passed into John (*sic*) Amory."

See an edition of the *Life of John Bunce* by E. A. Baker (1904); also W. Hazlitt, "On John Bunce," in vol. i. of the 1902 ed. of Hazlitt's *Works*; and G. Saintsbury, "Growth of the Modern Novel," in the *Cambridge History of English Literature*, vol. xi.

AMOS. I. The Book.—Like others of the Prophetic books of the Old Testament, the Book of Amos is a compilation which probably reached its present form long after the time of the prophet whose words it enshrines. We can trace the usual three types of source: (a) oracular matter, comprising most of this book; (b) reminiscences either written or dictated by the prophet himself, usually in prose (vii. 1-8, viii. 1-3, ix. 1-4)—these are accounts of the prophet's intercourse with his God while in the familiar condition of "ecstasy"; and (c) narrative by a third person describing an event in the life of the prophet (vii. 10-17). The passages under heading (a) consist of short, sometimes fragmentary, sections, each embodying an individual and separate message; some of them seem to be snatches from hymns of praise, which may or may not be the work of Amos himself (*e.g.*, v. 7, 8-9), and the final compiler seems to have appended to his collection a hopeful section by a later hand (ix. 8b-15), which was intended to tone down the uniform gloom of the prophet's predictions. Possibly the prophet himself was responsible for the arrangement of the oracles on the nations (i. 3-ii. 7a); if not, then the compiler of this section shows a rhetorical and dramatic power not unlike that of the prophet himself.

II. The Man.—Amos, whose activity is to be dated about 760 B.C. (viii. 9 suggests that Amos had experienced the eclipse of 763), was a native of Tekoa, in southern Judah. He belonged therefore, to a social order which still remained largely pastoral, and, though he knew the agricultural and commercial life of central Palestine and its cities, he approached it as an outsider. He himself lived the life of the semi-nomad, accustomed to the wide spaces of the southern hills, where the appearance of two travelers together was a rarity to be explained only on the ground that they had planned to journey together. He knew the habits of the lion, the bear, the birds, the snakes, and of those who hunted them or feared them. Though clearly an "ecstatic" (Heb. *nābî*), he indignantly repudiated the suggestion that he belonged to the professional party of "prophets" whose interference in politics had produced a revolution 100 years before his time. But he had the

clearness of insight which comes from lonely communion with nature, and he had, too, the intense conviction that it was the word of his God that he had to deliver.

III. His Message.—Since the days of David, Israel had been growing steadily out of the old nomad social and economic order into that of a commercial and agricultural state. Such a transition is always attended with risks, and these had become most obvious in the century preceding Amos. The old system of small proprietors, prevalent up to the middle of the 9th century, had given way to large estates worked by serf or slave labour. The result was a national emasculation, and the means by which the change was produced involved not only a failure to appreciate the demands of humanity, but also commercial immorality and shameless judicial corruption. Popular religion, to some extent inherited from the Canaanites, gave no help; on the contrary it condemned the would-be reformer (vii. 10 *seq.*), and its methods and ritual proved to be diametrically opposite to the real interests of morality. On the one hand, Amos found extravagant luxury, jingoism and oppression; on the other a proletariat from whom all virility had been crushed. Such a state could not hope to survive.

Unlike the Rechabites, who stood for a return to the simpler conditions of the nomad stage, Amos had no social programme to offer. Instead, he called men back to the God of their fathers, and insisted that the nation could find safety only in moral and spiritual reform. He presented men with a God who was essentially Law, acting not by casual whim but on invariable principle. To him the God of Israel was the Lord of creation, of history and of universal morality, and His supreme demand was for *justice*. That alone could save the people from their impending fate, for that alone would admit in practice the rights of human personality. The supreme contribution of Amos to the world's religious thinking was that he insisted that God is *good*.

Among English works on Amos the most advanced is Harper's *Commentary (Internat. Crit. Comm.)*, to which should be added Driver's *Joel and Amos* and Sir G. A. Smith's *Twelve Prophets*. More recent work of a popular type is to be found in J. E. McFadyen's *Cry for Justice* and the chapter on this book in *Prophecy and the Prophets in the Old Testament* by T. H. Robinson, who has also published a translation in colloquial English. (T. H. R.)

AMOSITE, a variety of asbestos characteristic of a definite geological horizon in the Lydenburg and Pietersburg districts of the north-eastern Transvaal; it possesses well developed fibrous structure and the colours range through greys and whites to yellowish greys. The material is a silicate of iron containing also magnesia and lime or soda. The deposits contain a high percentage of long fibres; spinning stock 4–7 in. in length is common and lengths up to 11 in. have been observed. The name is derived from the synthetic word *Amosa*, made by combining the initial letters of the name of one of the principal producing companies, Asbestos Mines of South Africa; the term was suggested as a distinctive trade name by A. L. Hall (Geol. Survey, Union of South Africa) in recognition of the distinctive characteristics of the fibre.

AMOY (24° 27' N. 118° 4' E.), a treaty port in the province of Fukien on the highly indented south-eastern coast of China. It lies at the head of a wide bay, studded with islands, into which flows the Kiulung river, whose basin occupies the south-east of the province. The harbour lies in the lee, *i.e.*, to the west, of Amoy island and is one of the finest on the coast. Its natural hinterland comprises only South-east Fukien and its trade with the interior is becoming more and more confined within these limits. In the past it has had a much larger significance, for it lay on that part of the Chinese coast first reached by traders approaching China by sea from the Indian Ocean. Both the English and Dutch first traded with China through Amoy which in the 18th century monopolized the Chinese junk trade to the "Straits" and Java. It still retains close connections with Malaya whose Chinese population is drawn largely from Fukien and emigrates mainly through Amoy. This relationship with Malaya is illustrated by the foundation of Amoy university by K. K. Tan, a Fukienese, by means of wealth acquired in Malaya. Moreover, Amoy has had trading relations with Formosa, once part of Fukien, but since the cession of Formosa to Japan these have become less intimate. Its tea export, once its staple trade, drawn

originally from Fukien itself and later from Formosa, has dwindled away. Although its total trade has risen in value from Hk.Tls. 10,058,401 in 1867 to Hk.Tls. 37,648,311 in 1926, it has fallen among Chinese ports from 8th to 15th place and in population from 300,000 to 114,000. Amoy is a port of call for coastal steamship services, has ship-repairing facilities and industrial activities, such as canning and sugar-refining, arising out of the sub-tropical agriculture of its hinterland. The foreign population resides in a self-governing international settlement on Ku-lang Su island, across the harbour from Amoy island.

AMPELIUS, LUCIUS, possibly a tutor or schoolmaster, and author of an extremely concise summary—a kind of index—of universal history (*Liber Memorialis*) from the earliest times to the reign of Trajan. The little work, in 50 chapters, gives a sketch of cosmography, geography, mythology (chaps. i–x.) and history (chap. x–end). The historical portion, dealing mainly with the republican period, is untrustworthy, and the text in many places corrupt; the earlier chapters are more valuable and contain some interesting information. In chap. viii. (*Miracula Mundi*) occurs a reference to the famous sculptures of Pergamum, discovered in 1871, excavated in 1878, and now at Berlin: "At Pergamum there is a great marble altar, 40ft. high, with colossal sculptures, representing a battle of the giants." Nothing is known of the author.

The first edition of Ampelius was published in 1638 by Salmasius (Saumaise) from the Dijon ms., since lost, together with the *Epitome of Florus*; the latest edition is by Wölfflin (1854), based on Salmasius's copy of the lost codex.

See Gläser, *Rheinisches Museum*, ii. (1843); Zink, *Eos*, ii. (1866); Wölfflin, *De L. Ampelii Libro Memoriali* (1854).

AMPELOPSIS, a genus of the vine family, Vitaceae, strongly resembling the grape-vine in habit, comprising some 25 species native to warm regions in Asia and North America, some of which are cultivated as ornamental climbers. Of these, the pepper-vine (*A. arborea*), somewhat shrubby, with pinnate leaves, and the simple-leaved ampelopsis (*A. cordata*) occur in the southern United States. The Virginia creeper (*q.v.*) was formerly placed under this genus; while *A. cuspidata* (*A. Veitchii*), introduced into England from Japan in 1868, has smaller leaves very variable in shape.

AMPÈRE, ANDRÉ MARIE (1775–1836), French physicist, was born at Polémieux, near Lyons, Jan. 22, 1775. When Lyons was taken by the army of the Convention in 1793, the father of Ampère, holding the office of *juge de paix*, was thrown into prison, and soon after perished on the scaffold. This event produced a profound impression on the susceptible mind of André Marie, and for more than a year he remained sunk in apathy. From about 1796 he gave private lessons at Lyons in mathematics, chemistry and languages; and in 1801 he removed to Bourg, as professor of physics and chemistry, leaving his ailing wife and infant son at Lyons. His wife died in 1804 and he never recovered from the blow. In 1809 he became professor of mathematics at the École Polytechnique in Paris. Here he continued his scientific researches and multifarious studies with unabated diligence. He was admitted to the Institute in 1814.

It is on the service that he rendered to science in establishing the relation between electricity and magnetism and in developing the science of electro-magnetism, or, as he called it, electro-dynamics, that Ampère's fame mainly rests. On Sept. 11, 1820, he heard of H. C. Oersted's discovery that a magnetic needle is acted on by a voltaic current. On the 18th of the same month he presented a paper to the Academy, containing a far more complete exposition of that and kindred phenomena (*see ELECTROKINETICS*). The whole field thus opened up he explored with characteristic industry and care, and developed a mathematical theory which not only explained the electro-magnetic phenomena already observed but also predicted many new ones. His original memoirs on this subject may be found in the *Ann. Chim. Phys.* (1820–1828). Late in life he prepared a remarkable *Essai sur la philosophie des sciences*, and wrote many scientific papers, including two on the integration of partial differential equations (*Jour. École Polytechn.*, x., xi.). He died at Marseille on June 10, 1836. The great amiability and simplicity of Ampère's character are well brought out in his *Journal et correspondance* (1872).

AMPÈRE, JEAN JACQUES (1800-1864), French philologist and man of letters, only son of André Marie Ampère, born at Lyons. In an extended tour in northern Europe, he studied the folk-songs and popular poetry of the Scandinavian countries. Returning to France, he delivered in 1830 a series of lectures on Scandinavian and early German poetry at the Athenaeum in Marseille. The first of these was printed as *De l'Histoire de la poésie* (1830), and was practically the first introduction of the French public to the Scandinavian and German epics. Ampère became professor of the history of French literature at the Collège de France. A journey in northern Africa (1841) was followed by a tour in Greece and Italy, in company with Prosper Mérimée and others. This bore fruit in his *Voyage dantesque* (printed in his *Grèce, Rome et Dante*, 1848), which helped to popularize the study of Dante in France. In 1848 he became a member of the French Academy, and in 1851 he visited America. From this time until his death at Pau he was occupied with his chief work, *L'Histoire romaine à Rome* (1861-64).

BIBLIOGRAPHY.—The *Correspondance et souvenirs* of A. M. and J. J. Ampère (1805-54) was published in 1875. Notices of J. J. Ampère are to be found in Sainte-Beuve's *Portraits Littéraires*, vol. iv., and *Nouveaux Lundis*, vol. xiii.; and in P. Mérimée's *Portraits historiques et littéraires* (2nd. ed., 1875).

AMPÈRE, the practical unit of electric current. It is equal to 10^{-1} absolute electro-magnetic units. (See PHYSICAL UNITS.)

AMPERE METER or **AMMETER**, an instrument for measuring electric currents. Ammeters used for the measurement of *direct current* are moving iron or moving coil low resistance galvanometers (see GALVANOMETER). In the latter form of instrument the current passes through a coil hung in the field of a permanent magnet, and this causes a deflection of the coil to which a pointer is attached. This is more widely employed than the moving iron type on account of its more efficient damping, which is due to eddy currents set up in the instrument, and in the best types of precision instruments the pointer attains its equilibrium position in less than a second. For measuring *alternating current* by means of an electromagnetic ammeter, the instrument is, in general, a form of dynamometer (*q.v.*). It measures, by their relative motion, the current flowing through two sets of coils which are connected in series, so that a change in direction of current affects both simultaneously, with the result that their relative movement is unchanged and depends on the magnitude of the current alone. The Duddell galvanometer is an alternating current electromagnetic ammeter which indicates the magnitude of the current by means of the relative motion of two straight parallel portions of a single wire carrying the current and situated in a permanent magnetic field. The *hot wire ammeter* may be used to measure either alternating or direct current, the movement of its pointer depending on the linear expansion of a wire when it is heated by the current.

AMPERSAND, the name of the sign, & or &, which is a combination of the letters *e*, *t*, of the Lat. *et*, and; a corruption of the mixed English and Latin phrase, "and *per se* and," of which dialect forms are, "ampussyand," or "amperseand."

AMPHIARAUS, a celebrated seer and prince of Argos, son of Oicles (or Apollo) and Hypernestra. He took part in the voyage of the Argonauts and in the chase of the Calydonian boar. He foresaw the disastrous issue of the war against Thebes and at first refused to share in it; but Eriphyle, bribed by Polyneices with the fatal necklace of Harmonia, persuaded him to set out on the expedition. Knowing his doom, he bade his sons, Alcmaeon and Amphilochus, avenge his death upon their mother.

On the defeat of the Seven, Amphiarus, pursued by Periclymenus, would have been slain had not Zeus opened a chasm into which the seer, with his chariot and horses, disappeared. Henceforth he was numbered with the immortals and worshipped as a god. Near Oropus, on the supposed site of his passing, his sanctuary arose, with healing springs and an oracle famous for its interpretation of dreams (Pausanias i. 341-342). There was another temple dedicated to him on the road from Thebes to Potniae, and here was the oracle of Amphiarus consulted by Croesus and Mardonius.

See Herodotus viii. 134; Pindar, *Olymp.* vi., *Nem.* ix.

AMPHIBIA, the term applied to one of the six classes of vertebrate animals. This class includes the frogs, toads, salamanders and coecilians, forms which stand in the zoological scale midway between the fishes and the reptiles. Many aquatic animals, such as crocodiles and seals, are amphibious, but, as their organization shows, belong to some other class of vertebrates.

The term Batrachia is still employed by many students of systematic zoology, although Stejneger made it clear that this name

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 1.—THE HARMLESS ITALIAN CAVE SALAMANDER, HYDROMANTES ITALICUS (DUNN) THAT CLIMBS UP VERTICAL SURFACES OF ROCK IN SEARCH OF INSECT PREY. BECAUSE OF ITS COLD, MOIST SKIN THE SALAMANDER WAS BELIEVED IN MEDIAEVAL TIMES TO BE IMMUNE TO THE ACTION OF FIRE

is a pure synonym of the much older term Salientia of Laurenti. The arguments for and against the use of the term Amphibia have been given in detail by Boulenger but his conclusion in favour of the term Batrachia has not been accepted by the majority of herpetologists to-day.

Amphibia are cold-blooded vertebrates having a smooth or rough, but not scaly skin, very rich in glands. Most have four legs and live on land, but, unlike other tetrapods, they respire to a large extent through their skin. The eggs are usually laid in the water, the larva passing through an aquatic existence before metamorphosing into the gill-less adult. The eggs, even when laid on land, are without a calcareous shell, and do not develop the amnion or allantois of higher vertebrates. Modern Amphibia are readily distinguished from reptiles by many differences of skeleton, but the most primitive fossils were so similar to contemporary reptiles that no sharp distinction can be made between them. Recent palaeontological finds have also tended to bridge the gap between Amphibia and the fishes, but here a complete series of intermediate forms is still lacking. Modern Amphibia are the specialized descendants of a great group of more or less aquatic forms living in late Palaeozoic and Triassic times. It is these extinct forms which represent the actual ancestors of reptiles and to them one must turn for the ground plan of skeletal organization from which all higher types evolved.

EVOLUTION

The First Land Vertebrates.—The most primitive of the fossil Amphibia are unquestionably the Embolomeri. Already in Carboniferous times the group contained, as shown by Watson, "primitively aquatic animals which show no signs of ever having possessed terrestrial ancestors," as well as others which were obviously terrestrial, and still others which had secondarily returned to life in the water. "Despite their diverse habits, the fundamental morphology of the skeleton is strikingly uniform throughout the group." It is clear from the researches of Watson that the ancestral fish changed to a tetrapod before the latter became permanently adapted to land life.

The first tetrapods, therefore, swam in the waters with their fish ancestors. *Eogyrinus*, the best known of these most primitive tetrapods, had a long body and probably a flattened tail. It very probably lived on fishes in the pools of a rather arid and quickly drying country. As the pools dried up *Eogyrinus* would move, or at least was equipped to move, in the manner of an eel overland to other pools. Its skull agreed closely with that of its osteolepid ancestors differing chiefly in having a long tract of the basis cranii unossified, permitting a certain movement in the

skull. The spiracular notch was very likely covered by a tympanic membrane for, as shown in certain other Embolomeri, the hyomandibular had already been converted into a stapes, even though no opening for its insertion into the otic capsule had yet appeared. The pectoral girdle was attached to the skull by post-temporals as in many fish, and this girdle differed from the primitive bony fish apparatus only in the addition of the interclavicle, a new dermal element, to its ventral surface in the mid-line. The pelvis was not firmly attached to the vertebral column as in later vertebrates, but the ilia rested on long sacral ribs and were held by muscles very much in the same way that the scapula is secured in the thorax. The limbs were small and capable of only a limited motion in any direction.

The Embolomeri are the most primitive labyrinthodonts and gave rise directly to the Rachitomi, and the latter in turn to the Stereospondyli. The Phyllospondyls and Lepospondyls, already present in the Carboniferous, evolved either from specialized Embolomeri or primitive Rachitomi. There is no good evidence of these having arisen independently from fishes. The urodeles and frogs have come from Phyllospondyls, while the coecilians seem to have arisen from Lepospondyls. Fossil intermediates between any modern Amphibia and these ancient orders are lacking and our conclusions are based on a comparison of their skeletal characters.

The Skeleton.—Once vertebrate life was established on land it reverted not once but many times to the aquatic habitat long before the modern Amphibia appeared. Despite the frequent change of habitat the skeletal organization of the first Amphibia continued to evolve steadily in definite directions with time. In recent Amphibia, too, the fundamental structure has changed slowly while the various groups may show the widest adaptations. Ranids may be arboreal, aquatic or fossorial; plethodontids may be the same.

Skull.—The first tetrapods inherited a skull very similar to that of their fish ancestors. It consisted of a cartilaginous box or chondocranium, covered completely above by dermal bones and internally strengthened by bones which replaced the cartilage in part. This skull, the prototype of all tetrapod skulls, differed remarkably from that of modern Amphibia by the far greater number of skull elements it contained, by the greater ossification of the chondocranium and by its reptile-like form.

The skull of the Embolomeri agreed in most details with that of the osteolepid fishes. The skull roofs were similar (figs. 2 and

3), except for a cluster of small bones in the nasal region in osteolepids. The distribution of the lateral line canals in both skulls facilitates the identification of lacrymal, prefrontal, jugal, post-orbital, postfrontal, supra and intertemporals. The spiracular notch of *Osteolepis* has become the otic notch and the elements bordering this and the orbit may be readily homologized (fig. 2). The palates agree remarkably in the small size of the interpterygoid vacuities and the almost identical position of the palatal and jaw bones (fig. 3). The large pterygoids are bordered externally by the prevomers, palatines and ectopterygoids. The distribu-

tion and replacement of the large teeth are identical in fish and tetrapod. An internal nares is present in all osteolepids and "is identical in position, size, and borders with that of certain Embolomeri." The osteolepids very probably breathed air in the manner of the Embolomeri.

The lower jaw of the first tetrapods differed greatly from that of modern Amphibia in the far greater number of elements it contained. It was, however, identical with that of the osteolepid jaw.

B. *Baphetes*

The brain case of osteolepids and Embolomeri were very similar but not identical. In both the basioccipital formed a circular condyle perforated by the notochord. The exoccipitals extended upwards to a well-developed supraoccipital. The basisphenoids of both had definite basiptyergoid processes with which epiptyergoids articulated. The great difference is seen in the palatal view. The osteolepids had a large part of their basis cranii unossified. In this they differed from all other vertebrates, save their descendants, the coelacanth. This character would seem to exclude the osteolepids from the immediate ancestorship to the tetrapods, but the numerous resemblances of brain case, skull roof and jaws show that the osteolepids must have been closely allied to the ancestor fish.

Once this reptile-like, highly ossified and complex skull of the ancestral fish became established in land forms, it underwent an enormous specialization. The successive stages in its specialization may be traced in the Rachitomi and Stereospondyli and to a lesser extent in the other orders of Amphibia. Very soon there began a progressive fenestration, the bones tending to segregate along lines of greatest stress. The solid dome-like skull roof progressively lost various dermal elements until in the modern frogs only the premaxillary, maxillary, nasal, quadratojugal, squamosal, frontal and parietal are left. The more primitive urodeles still retain a lacrymal and prefrontal in addition to the frog's equipment. The quadratojugal, although appearing as a separate element during ontogeny in the urodeles, later fuses with the quadrate. This loss of elements was perhaps largely due to a shortening of the skull. The Embolomeri had 12 cranial nerves; and in the evolution of this group and the Rachitomi the hypoglossal foramen in the exoccipital is carried farther backward until in the most specialized labyrinthodonts, the Stereospondyli of the Upper Trias, it no longer perforates the skull wall, the twelfth nerve passing out behind the skull as in modern Amphibia.

The second great change which developed as the tetrapod

series evolved was the gradual flattening of skull. It changed from tropibasic to platybasic, not the reverse as some embryologists have maintained. The trabeculae were no longer squeezed together, and the interorbital septum became hollowed out into a trough.

The third fundamental change was a progressive weakening of the bony organization of the skull. The brain case became progressively less well ossified. Basioccipital, basisphenoid and supraoccipital became reduced and disappeared. Hence, the original tripartite condyle became converted into a pair of well separated exoccipital condyles. The tripartite condyle is retained in many reptiles, but in the promammals a withdrawal of the basioccipital leads to a condition exactly parallel to that of modern Amphibia.

On the palate the interpterygoid vacuity became progressively wider (fig. 3). The pterygoid lost its connection with the basipterygoid process and higher labyrinthodonts depended entirely on the parasphenoid for its support. In frogs and certain primitive urodeles (some hynobiids, etc.) the pterygoid cartilage extends forward and fuses with the nasal capsule. The bony pterygoid which forms around it has much the form of the pterygoid of the Rachitomi but posteriorly it makes different contacts. The ectopterygoid is lost in all urodeles and frogs but still retained in a few coecilians. The palatine is variable in occurrence. Within a single genus of frogs some species may possess and others lack an ossified palatine. The most remarkable changes occur in the prevomer of modern forms. In urodeles the palatine undergoes a radical change at metamorphosis, part becoming lost and part apparently fusing with the prevomers. This combined prevomer and palatine tends to invade the parasphenoid region in the various families of urodeles, sending back long dentigerous processes on either side of the parasphenoid region (salamandrids) or ventral to it (plethodontids). In most plethodontids the posterior processes break off as one or two separate dentigerous areas overlying the parasphenoid as "parasphenoid teeth." A few frogs (brevicipitids) have succeeded in similarly dividing the prevomers, but the posterior elements overlie the palatine, not the parasphenoid region. A few others have the prevomers fused into a single element (*Xenopus*). In all urodeles except certain primitive salamandrids and hynobiids and a few higher forms, the pterygoid fails to reach the maxilla, and in the *Plethodontidae* it never ossifies at all, although it may extend forward to the maxillae. It is the reduced pterygoid and maxilla which make the urodele palate seem so unlike the anuran, although they are both fundamentally alike and referable to the Rachitomi plan. If the palate of such a primitive salamandrid as *Tylotriton* is compared with that of a frog or of *Eryops*, the fundamental resemblance becomes obvious.

The most reduced part of the modern amphibian skull is the lower jaw. The Embolomeri inherited a complex mandible of ten pieces. In the Rachitomi and Stereospondyli there occurs a gradual reduction of the mandible in width, a loss or fusion of elements, until in primitive urodeles there was left only a dentary, a prearticular and articular and an angular. Coronoids are present in the larvae of most urodeles. The angular is fused with the prearticular in all urodeles above the *Cryptobranchioidea*. In coecilians a very early fusion of the jaw elements occurs in most genera, but the resulting element probably contains a coronoid as well as the dentary, articular and prearticular, for two rows of teeth are present in many forms. In the Salientia the reduction is carried to an extreme, for only the dentary and prearticular are recognizable. The articular ossifies in very few Salientia and is then fused to the prearticular. The anterior end of Meckel's cartilage ossifies as a pair of distinct elements in some *Ranidae*, *Hylidae* and *Bufo*nidae.

While the changes in the skull and jaws discussed above proceeded regularly in the evolution of the Amphibia and may be classified as trends of evolution or orthogenetic changes without a primary adaptive significance, there were other modifications taking place which seem more definitely correlated with the environment. Perhaps the most important of these were those associated with the ear. The first tetrapods as represented by *Eogyrinus*

possessed a stapes and very probably a tympanic membrane, but no fenestra ovalis. The sound waves were thus transmitted from the stapes through the otic capsule. This condition was scarcely different from that of fishes where no stapes was present. Another piscine character was the absence of a cranial wall between the labyrinth and the brain. The latter character was handed on to certain Rachitomi but later Amphibia walled off the auditory apparatus from the brain, leaving only a foramen for the auditory nerve. With the assumption of land life the fenestra ovalis was completed in the lateral wall of the otic capsule. The Salientia inherited this auditory apparatus in a slightly modified form. All Caudata have suffered a loss of the tympanum and middle ear. The stapes is connected in the larva with the quadrate, and sound waves are transmitted through the lower jaw resting on the substratum to the quadrate and thence via the stapes to the inner ear. In the metamorphosed individual the head is raised from the ground and the stapes is usually connected by a muscle with the shoulder girdle. Vibrations are thus apparently sent through the fore-legs of the adult urodele to the ear.

The osteolepid ancestors of the Amphibia had five branchial arches, while the modern Amphibia have at most four. The latter possess, however, a pair of laryngeal cartilages which may or may not represent the fifth branchial arch. The gill arches in the adult urodele or frog are modified by reduction and fusion.

Vertebrae.—The major groups of the Amphibia are classified to a large extent on the form and composition of their vertebrae. To evolve the first tetrapod vertebrae from those of their fish ancestors did not require any radical alterations. The immediate ancestors of the Embolomeri are not known to have embolomeric vertebrae, but they probably had vertebrae which could be easily resolved into the embolomeric type. Most fish and Amphibia have the vertebrae more or less ossified and the cartilaginous blocks of the embryonic vertebrae after certain unequal growths fused. The basidorsals almost invariably grow up and around the neural tube tending to enclose it as a neural arch. The basiventral may either grow up around the notochord or it may remain rudimentary, while the basidorsal grows down toward it. The interdorsal and interventral may fuse and ossify or remain separate either ossifying or not. In the tail region of the fish *Amia* the interdorsals sometimes fuse with the interventrals but not with the basiventral. Thus, each neural arch may have two centra, an embolomeric condition. In the body region of the same fish interdorsals, interventrals and basiventrals may fuse as a single centrum.

Such a variability of vertebral composition becomes greatly restricted in the Amphibia. The first tetrapods retained the embolomeric or double centrum type of vertebrae for their entire column. The Rachitomi, being more cartilaginous, have the four pairs of embryonic blocks ossified, but separate, producing the rachitomic or "backbone-cut-into-pieces" type. In the most specialized labyrinthodonts a decided one-sided growth of the blocks has occurred, for the centrum is composed entirely of basiventral, the interdorsal and interventral either being greatly reduced or remaining cartilaginous.

The Lepospondylia and Phyllospondylia have sprung from either the Rachitomi or from a labyrinthodont stock slightly more specialized than the known Embolomeri. Their vertebrae are more embryonic than that of the Embolomeri in that the notochord is less restricted by the surrounding centrum. The vertebrae are, on the other hand, more specialized in that the interdorsal and interventral remain cartilaginous (i.e., are not present in the fossils), the definitive centrum being formed by the basidorsal and basiventral which may remain separate in some branchiosaurs, but always fuse into a single ring in the microsaur. In both these orders the vertebral column seems to consist of a series of rings, one for each somite, the septum, as shown by the position of the rib being, therefore, between the successive vertebrae unless by a secondary shifting, such as occurs in modern Amphibia, the rib arises from the side of the vertebra. All Phyllospondylia have their ribs arising in this secondary position while most Lepospondylia retain the more primitive position.

Primitive urodeles and frogs (*Liopelmidae*) have vertebrae

which are very similar to those of Branchiosaurs, except that they are more ossified. Further, in the trunk region of the recent forms, the basiventrals remain very small, and the main part of the centrum is formed by the basidorsals. Interdorsals and ventrals remain cartilaginous in the primitive types of modern Amphibia and frequently, as in *Ascaphus*, no joints are formed between the successive vertebrae. In the higher forms, however, the intervertebral cartilage (interdorsal plus interventral fused)

splits in such a way as to form a ball-like surface on the anterior (opisthocoelus) or on the posterior end (procoelus) of the vertebrae. Usually in Salientia and frequently in Caudata the articular ball calcifies or ossifies. In a few frogs (*Megalophrys*, etc.) the ball may remain quite free of either the vertebrae before or the one behind it. This ball has been called a centrum by various authors. As it contains almost all of the interdorsal and interventral tissue it is homologous to the centrum of reptiles and mammals, but not to that of the Phyllospondyls, Lepospondyls or Stereospondyli. In the Salientia the form of the vertebrae as determined by the manner of fusing of the intervertebral ball affords one of the primary characters of classification.

The Salientia are in various features of their skeleton more primitive than the urodeles, but the development of their vertebrae is far less diagrammatic. In the most extreme types, some terrestrial (*Pelobatidae*), others aquatic (*Pipidae*, *Discoglossidae*) the basidorsals and ventrals extend only a short distance towards each other before metamorphosis. At this time the notochord is greatly reduced and a much flattened vertebra results, formed, except for the articular ball, almost entirely by the basidorsal. The explanation of these coenogenic features may rest in the large notochord and very active tadpoles found in these forms. The developmental history if taken alone would throw very little light on the past history of these vertebrae.

Ribs.—The ribs of primitive Amphibians and reptiles articulate with all vertebrae, at least as far back as the middle of the tail. In phylogeny the sacral ribs become fused to the vertebrae first, then the caudals, next the lumbar, the cervical and finally the thoracic. In elongate urodeles the ribs have become reduced in number. *Siren* and *Amphiuma* have only the anterior thoracic vertebrae still retaining the ribs. In frogs the reductions have reached an extreme. *Discoglossids* retain three, *liopelmids* only two ribs in the adult. The *pipids* have two ossified ribs in the larva, but these fuse later to the diapophyses. The bits of cartilage on the ends of the diapophyses of the higher frogs have been considered homologues of the ribs. This is perhaps a matter of definition. No ossified ribs appear as distinct elements in the development of any Salientia above the *Pipidae*.

The ribs are long in the primitive labyrinthodonts and surround the body as a series of hoops. They never meet in the mid-line and never connect with the sternum. In some higher Rachitomi (*Cacops*) the ribs are short and directed outward. The microsaurs have long curved ribs, the branchiosaurs and modern Amphibia very short and rod-like ones. The ribs are shortest in the frogs and the long-bodied perennibranchs; longest in the primitive salamandrids. In *Tylotriton*, and its close relative *Triturus waltli*, the tips of the ribs may be long, pointed and actually protruding through the skin. This apparently serves as

a special mode of protection, for when the animal is quickly seized the needle-like ribs may give a sharp prick.

The ventral side of the body of many Labyrinthodontia, Lepospondylia and Phyllospondylia were sheathed with a coat of closely set rods or plates. These apparently gave rise to the abdominal ribs of reptiles. In modern Amphibia only *Liopelma* has large myoseptal cartilages of apparently the same form as the abdominal ribs of lizards, but a few urodeles have splints of cartilage in a few of the myosepta which may possibly be similarly interpreted.

Pectoral Girdle.—The pectoral girdle of the first tetrapod was practically identical to that of the primitive bony fish except that a new dermal element, the interclavicle, had been added to its ventral surface in the mid-line. Four pairs of dermal elements were present in the first land vertebrates in addition to the interclavicle. These formed a half ring of bone on either side of the body directly behind the branchial arch region. The cartilage bones which form the bulk of the pectoral girdle of modern Amphibia were represented in these primitive forms merely as a simple buttress for the humerus on each side. Such a buttress may be called a scapula or a scapulo-coracoid, for it is only in the higher Amphibia that this ossifies from two centres.

Aquatic labyrinthodonts secondarily broadened their clavicles and interclavicles. A similar broadening of the ventral girdle elements is found in many modern Amphibia which are wholly aquatic. The dermal elements, however, continued to dwindle in the higher Amphibia. This seems to be directly correlated with a greater development of the leg and shoulder musculature brought into play by the increased use of the forelimbs.

The branchiosaurs possessed a pectoral girdle very similar to that of the Rachitomi but more cartilaginous. The entire glenoid and coracoid regions remained unossified. A somewhat similar difference distinguishes the pectoral girdle of certain aquatic urodeles from that of their more terrestrial relatives.

The Salientia have retained the pectoral girdle of the more terrestrial Rachitomi in almost its entirety. The interclavicle has been lost and a new structure, the omosternum, has arisen by a forward elongation and usually a division of the coracoid cartilages. The broadened ventral ends of scapulo-coracoid bars have become fenestrated. The posterior rim ossifies as a separate centre, the coracoid, while the mesial and anterior part usually remains cartilaginous. The anterior rim is called the procoracoid, while the mesial part the coracoid cartilage. In spite of these different names the fundamental resemblance of the pectoral girdle of frog and labyrinthodont is obvious.

In higher Salientia many modifications of the pectoral girdle occur. In different families the coracoid cartilages may fuse in the mid-line producing a firmisternal type of girdle. In the *Brevicipitidae* procoracoid and clavicle may become lost entirely. Omosternum and sternum are subject to either ossification or loss. In the *Ranidae* and the *Polypedatidae* the former may become widely forked posteriorly. The sternum was possibly cartilaginous in the labyrinthodonts and branchiosaurs, although as it is never found fossil in these groups its presence has been denied. The sternum in the most primitive Salientia resembles greatly the abdominal ribs and may, in fact, have arisen from this series of elements.

The urodeles are specialized in the complete loss of the dermal elements. As if in compensation for this loss the coracoid cartilages are usually broadly dilated. The deltoid region has become extended into a long, so-called procoracoid in most forms, but the primitive genera of several families retain this in a less extended condition. The urodeles are primitive in that the scapulo-coracoid usually ossifies as a single piece, the ossification often extending far down into the coracoid region producing a structure very much as in *Eryops*; in *Siren* and *Pseudobranchius* the posterior ventral margin of the cartilage ossifies as a separate coracoid.

Pelvic Girdle.—The pelvic girdle of the first tetrapods has advanced beyond the conditions found in fishes in that a pubis, ischium and ilium are present meeting in the acetabulum in a triradiate suture. The ilium, however, was not firmly attached to the sacral ribs.

The ilium soon gained a firmer support to the sacral ribs, and even within the Embolomeri the girdle underwent some modification. *Diplovertebron*, according to Watson, failed to ossify its pubis, and this condition has been handed down to most modern Amphibia. The terrestrial labyrinthodonts retained a more ossified girdle which was almost indistinguishable from that of the contemporary cotylosaur reptiles.

Modern Amphibia have inherited the same plate-like pelvis of the primitive labyrinthodonts. The obturator foramen so characteristic of modern reptiles is not present and the pubis is usually unossified, as in the branchiosaurs and higher labyrinthodonts. In a few Salientia the pubis region is either calcified or ossified, but it rarely forms a separate bone. The pubis cartilage is of variable extent in the different families of urodeles, it being more extensive in aquatic than in terrestrial forms. A part of the pubis is unossified in even the most terrestrial Amphibia.

Many urodeles exhibit at the anterior end of the pubis a Y-shaped cartilage called an epipubis or an ypsiloid apparatus; as shown by Whipple, this structure serves to assist in controlling the form of the lungs in those urodeles which use this structure as a hydrostatic organ. It seems to be a neomorph in the urodeles, although certain liopelmids and pipids have a cartilaginous plate immediately anterior to the pubis. The primitive *Ascapheus* has developed a pair of rod-like cartilages which lie over the ventral surface of the pubis and function in directing forward the "tail" or copulatory apparatus of the male.

Limbs.—The Amphibia arose from some generalized cross-opterygian. The skeletons of the paddles of only two of these primitive types of fishes are known. These fin bones are leg-like in that they consist of a proximal element or humerus subtending two distal elements, a radius and ulna. The outer row of elements, however, are more numerous than the supporting elements in the hands or feet of tetrapods. Undoubtedly a series of fusions and losses must have occurred in the change from fin to limb. The modifications are confined to the distal segment of the appendage. The fundamental ground plan of single-proximal, double-median and multiple-distal elements was already well established in the fish ancestors of the tetrapods.

The chief problem in the origin of the chiropterygium concerns the distal segment of the limb. How many fingers and toes were present in the first land vertebrates and how many carpal and tarsal elements formed their support? Watson has shown that *Diplovertebron* had five well-developed fingers and toes, as in the case of the oldest reptiles. He finds no evidence of a sixth or seventh digital ray, such as has been described in the rachitomous *Eryops*. This makes it highly probable that the prepollex and postminimus, if present at all, were cartilaginous, as in certain recent reptiles and mammals.

All Amphibia above the Embolomeri had only four digits in the hand, but many, to judge from their tracks, must have had a well-developed prepollex. Further, *Eryops* apparently had a stout prepollex, a rudiment of the fifth finger and a cartilaginous block representing a sixth. The prepollex was originally a supporting ray on the inner side of the hand. In modern Salientia it is almost universally present and often hypertrophied in the male to ensure a better grip in amplexus. In urodeles, even in forms which are not known to practise an amplexus, the prepollex is sometimes present and even bony. The modern Amphibia inherited a prepollex, four digits and a rudiment of a fifth digit in the hand.

In the foot of modern Amphibia there are five digits present, as in *Diplovertebron*, but also in most Salientia a prehallux, and in some primitive urodeles, both a cartilaginous prehallux and a postminimus. In burrowing Salientia the prehallux is greatly enlarged to form the core of a "spade." This gives the impression that the prehallux is a recent adaptive structure which has arisen in connection with the burrowing habit. Its wide occurrence in non-burrowing forms is, however, against such a hypothesis. It seems highly probable that the prehallux is a fundamental element and that the original tetrapod foot, like the hand, was seven rayed.

The oldest known carpus and tarsus are both from rachitinous types. In both there is found the maximum number of elements

found in any Amphibian. The proximal row consists of four elements. Distal to this proximal row of elements there is a series of three elements called medialia by Schmalhausen, because of their position. Immediately distal to the medialia are the carpalia, 1-5 in the hand, and tarsalia, 1-5 in the foot.

Numerous fusions or, perhaps better, failures of the blastema to differentiate distinct elements have occurred in the carpus and tarsus of modern forms. The *Hynobiidae*, *Ambystomidae* and *Cryptobranchidae* approach most closely to the primitive condition. Some specimens of *Ranodon*, according to Schmalhausen, differ in their tarsus from *Trematops* only in that tarsalia 1-2 are fused. Urodeles with a reduced number of digits have suffered the greatest number of fusions. The Salientia have also diverged considerably from the primitive type. In the carpus fusions have occurred in all three rows. The discoglossids and pelobatids exhibit fewer fusions than the higher families. The tarsus of the Salientia is peculiar in the great elongation of the tibiale and fibiale, and the loss or fusion of all the other elements save three or four of the tarsalia. This elongation of the proximal series gives the frog's hind leg the appearance of having three long segments instead of the usual two. Such a specialization is undoubtedly an adaptation to jumping, although various species living to-day have given up that habit.

CLASSIFICATION

1. Labyrinthodontia.—Amphibia with a roofed skull, a lower jaw consisting of at least eight bones on each side and vertebrae consisting of neural arches and intercentra in all forms, with pleurocentra in addition in most.

The Labyrinthodontia are divided into three suborders, or grades: Embolomeri, Rachitomi and Stereospondyli. The first is from the Lower Carboniferous to Permian, the second, from the Permian and Triassic, and the last, from the Triassic. The skeletal organization of these groups has been discussed above. A detailed classification has been given by Watson.

2. Phyllospondylia.—Small, very highly specialized Amphibia with a roofed skull, palate with very widely open interpterygoid vacuities, coracoid and pubis not ossified; ventral armour of small round scutes. *Branchiosauridae*. Carboniferous and Lower Permian.

3. Lepospondylia.—Small Amphibia with roofed skull and lepospondylous vertebrae. *Nectridia*, *Diplocaulidae*, *Aistopodidae*. Carboniferous and Permian.

4. Gymnophiona.—Recent worm-like Amphibia without limbs and with a very short tail; male with an intromittent copulatory organ. Tropicopolitan, excepting Madagascar. Apparently evolved from the Lepospondylia, but fossil annectant forms lacking. Nineteen genera are recognized.

5. Caudata.—Salamanders and newts (*qq.v.*) are readily distinguished from other living Amphibia by their four limbs and tail. They are grouped into five suborders and eight families. The latter may be briefly characterized here.

(1). *Hynobiidae*.—A small group of Asiatic land salamanders distinguished from ambystonids, which they resemble externally, in having the angular free, premaxillary spines short not separating nasals and in practising external fertilization. There are five genera, but only *Hynobius* has a wide range.

(2). *Cryptobranchidae*.—Two genera of semi-larval salamanders of large size directly evolved from the hynobiids, and differing in retaining a few larval characters in the adult. *Cryptobranchus* (*q.v.*) of eastern United States is more larval than the Japanese-Chinese *Megalobatrachus*.

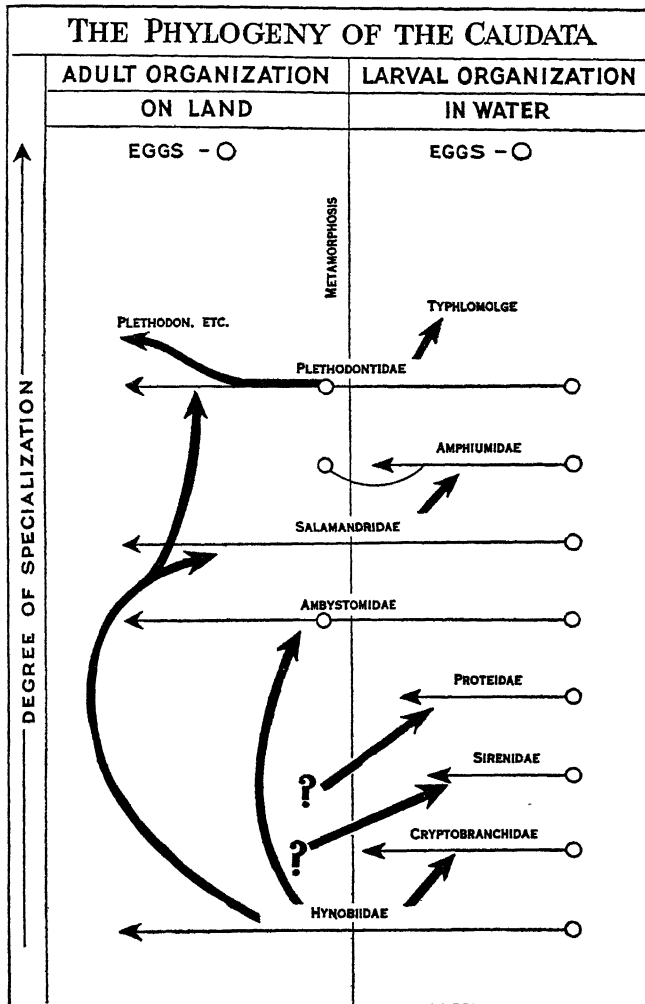

(3). *Ambystomidae*.—A family of common American salamanders distinguished from salamandrids by their short prevomerous and amphicoelous vertebrae, and differing from hynobiids in their fused angulars, long premaxillary spines and internal fertilization. The family includes three American genera, of which only *Ambystoma* with eleven species is well known.

(4). *Salamandridae*.—A varied group of aquatic forms, such as the newts, and terrestrial species, such as *Salamandra*, with vomerine teeth extending back as a series on each side of the parasphenoid and with the vertebrae opisthocelous. The primi-

tive salamandrids are large, rough-skinned newts, having a bony, fronto-squamosal arch, high neural spines, and long ribs. The more specialized forms show a reduction of these elements and also of the maxillaries, pterygoids and basi-hyals. The *Salamandridae* are found in North America, Eurasia and North Africa.

(5). *Amphiumidae*.—A family including only the genus *Amphiuma*. The large "Congo Eel" or Conger is a semi-larval type derived from the salamandrids and agreeing with them in most important characters. It possesses lungs, a bony pterygoid, a posterior process from each prevomer and premaxillary spines elongated to separate the nasals.

(6). *Plethodontidae*.—A large group of salamanders abundant in America and including both aquatic and terrestrial forms, with a pterygoid that remains cartilaginous throughout life and with vomerine teeth carried back by processes during ontogeny to form one or two dentigerous patches over the parasphenoid. All plethodontids are lungless and possess a naso-labial groove to assist in freeing the nostril from water.

DIAGRAM SHOWING THAT THE LARGE AQUATIC SALAMANDERS KNOWN AS PERENNIBRANCHS ARE NOT NECESSARILY PRIMITIVE SPECIES BUT PERMANENT LARVAE WHICH HAVE FAILED TO METAMORPHOSE. SOME HAVE GONE FARTHER IN THE METAMORPHIC PROCESSES THAN OTHERS

(7). *Proteidae*.—A group of permanently larval salamanders of unknown ancestry including only the European *Proteus* (q.v.) and American *Necturus*. Lungs are present, but the ypsiloid apparatus is absent. The pubo-ischium has a distinctive form, being long and pointed anteriorly. *Proteus* is a blind and pigmentless cave form while *Necturus*, represented by two species, is an active stream or pond dweller.

(8). *Sirenidae*.—Long-bodied *Siren* (q.v.) and *Pseudobranchius* of south-eastern United States form a group which agrees with the very young larvae of other families in possessing only the

anterior appendages and in lacking many later ontogenetic developments of the skull. They differ when adult from the young of other families in possessing reduced pterygoids, a separate ossification of the coracoid and a well-developed Jacobson's organ. Their relationships to the other families of Caudata is unknown.

6. *Salientia*.—The frogs and toads with their short, tailless bodies and long hind legs are distinguished from other living Amphibia. The order has been divided into four suborders, eleven families and many subfamilies, but only the families will be considered here.

FIG. 6.—MALE ASCAPHUS TRUEI (STEJNEGER), A PRIMITIVE FROG, SHOWING THE CLOACAL APPENDAGE OF THIS SEX. THE FIGURES ON THE RIGHT REPRESENT THE "TAIL" FULLY EXTENDED IN A BREEDING MALE

(1). *Liopelmidae*.—Primitive frogs with amphicoelous vertebrae and two pairs of ribs; a family including only *Liopelma* of New Zealand and *Ascaphus* of north-western United States. The latter is remarkable in possessing an extension of the cloaca in the male to form a "tail." This appendage is apparently used in copulation as fertilization is internal (fig. 6).

(2). *Discoglossidae*.—Primitive Old World frogs having opistho-coelous vertebrae, three pairs of ribs, sacral vertebra free with bi-convex centrum. The family includes only two European, one Eurasian and one Philippine genus.

(3). *Pipidae*.—Aquatic Salientia which have lost the tongue and movable eyelids (except *Pseudhymenochirus* which retains a lower eyelid). Ribs are free in the larva, but ankylose to the diapophyses on metamorphosis. Various fusions occur in the vertebral column, the presacral vertebrae numbering five to seven. The sacrum is fused to the coccyx (rarely free with a single condyle). The pectoral girdle is partly or wholly firmisternal, the cartilages never broadly overlap as in the *Discoglossidae*. The family includes the Surinam toad (q.v.).

(4). *Pelobatidae*.—Salientia without ribs at any stage of development, sacral vertebrae procoelous, ankylosed to coccyx or if free with only a single articular condyle for the latter; presacral vertebrae eight, either uniformly procoelous or with free intervertebral discs (interdorsals). The Pelobatidae agree with bufonids in the arciferal pectoral girdle and dilated sacral diapophyses; they differ from them in their single coccygeal condyle and primitive musculature. The family includes the spade-foot toads and certain forest frogs of the Seychelles, south-eastern Asia and the East Indies.

(5). *Palaeobatrachidae*.—Fossil frogs from the Jurassic, Oligocene and Miocene formations of Europe. They are procoelous, arciferal forms differing from the *Pelobatidae* in having a double condyle on the coccyx and in having the sacrum formed of two or three slightly dilated precoccygeal vertebrae. In limb proportions the *Palaeobatrachidae* approach the *Pipidae* and it is highly probable that the species were thoroughly aquatic.

(6). *Bufonidae*.—A dominant family of true toads (q.v.) and neotropical "frogs" having a uniformly procoelous vertebral column and a double condyle to the coccyx (rarely fused to sacrum). They are arciferal and resemble the *Pelobatidae* in many characters, but differ in musculature and coccygeal articulation. The toothed bufonids are frequently designated as *Cystignathidae* or *Leptodactylidae*. They are more primitive than the toothless genera, but as they have given rise to toothless bufonids in different parts of the world, it makes a more natural system to group both together as a single family.

(7). *Hylidae*.—Bufonids with an intercalary cartilage or bone between the last two phalanges of each digit and usually with claw-shaped terminal phalanges. They are procoelous and usually

with dilated sacral diapophyses. Most, but not all, are tree-frogs (*q.v.*) and a few, such as *Acris*, are semi-aquatic. There are 15 genera of hylids. All of these, save *Hyla* (including *Hylella* and *Nyctimystes*), are confined to the neotropical region.

(8). *Brachycephalidae*.—A large group of small neotropical toads recently shown to be closely allied to the *Bufo* and to have no relationship to the *Ranidae* or *Brevicipitidae* with which they were formerly confused; procoelous forms with the two halves of the pectoral girdle partly or wholly fused in the mid-line.

(9). *Ranidae*.—Firmisternal frogs (*q.v.*) with cylindrical or slightly dilated sacral diapophyses, digits without intercalary cartilages, sacral vertebra convex anteriorly, the eighth vertebra biconcave and preceded by seven procoelous vertebrae. Ranids are primarily Old World frogs, only one genus, *Rana*, reaching America. Africa seems to have been a centre of differentiation for the family, the greatest diversity of type occurring there.

(10). *Polypedatidae*.—Ranids with cylindrical sacral diapophyses and intercalary cartilages between the two last phalanges of each digit. The *Polypedatidae* are tropical tree-frogs of the Old World.

(11). *Brevicipitidae*.—A group of toads closely related to the ranids and differing chiefly in the more dilated sacral diapophyses. The more specialized forms have lost their teeth and all the ventral elements of the shoulder girdle save the coracoids. The family is cosmopolitan. Brevicipitids in the Asiatic, East Indian, and Malagasy regions seem to have run through independently on series of structural changes, often parallel in the three regions.

GENERAL MORPHOLOGY

Integument.—The skin of modern Amphibia may be rough and dry or smooth and moist, but it is never covered with scales as in nearly all reptiles. Many coecilians, however, have rings of minute scales hidden in the transverse folds of their skin. Aquatic or fossorial Amphibia, which rely to a large extent on their skin for respiration, usually have a thinner and smoother integument than terrestrial forms, but many exceptions to this rule occur, particularly in the *Pipidae* and *Bufo*. The fossil labyrinthodonts, phyllospondyls and lepospondyls were frequently well armoured with scales, especially on the ventral surface where

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 7.—HORNED TREE FROG (*CERATHYLA JOHNSONI*), AN AMPHIBIAN WHICH CAN CHANGE ITS COLOUR TO MATCH THAT OF ITS SURROUNDINGS, AND SO ESCAPE DETECTION

Secondary bony deposits in the form of plates, horns or pseudo-teeth are found on the skulls of many unrelated groups of Salientia

these scutes of varying shapes and sizes were arranged, for the most part, in orderly rows converging toward the mid-line. In a few salamandrids and many tropical Salientia a secondary deposit of bone forms in the deeper dermal tissues and may produce encrustations ankylosed to the underlying bones. The bizarre casques of *Pternohyla*, *Triprion*, *Cerathyla*, etc. are of this character (fig. 7). Less conspicuous bony covers to the skull appear in the spade-foot toads and various hylids, particularly the marsupial frogs. Similar bony growths extend to the derm of the back in various Salientia and in rare instances (*Brachycephalus*) may be ankylosed to the vertebrae. The epidermis covering warts or spines may be more or less cornified in modern Amphibia and in various urodeles (*Desmognathus*, *Necturus*, etc.) that on the digit tips is similarly modified. In a few hynobiids thick horny pads occur on the palms and soles, while in the larvae of others, the epidermis of the digits is extended into pointed claws. Similar horny claws occur on the three inner toes of the African pipids, and may have been found on all the digits of some extinct Amphibia, for in one of the most primitive labyrinthodonts the terminal phalanges have the form of curved claws.

The integument of modern Amphibia is further distinguished from that of reptiles in being highly glandular. There are two

main types of glands: the granular and the mucus. The first may be broadly distributed over the dorsal surfaces or massed in folds or warts on the sides of the body. Its secretion is creamy, very irritating to mucus membranes and poisonous when taken internally. The mucus glands are more uniformly distributed over the body. They produce a slime less irritating to the nasal passages and conjunctiva but, nevertheless, toxic when injected into lower animals. Amphibia differ enormously in both the quantity and kind of integumentary secretion. Some species, such as the toads, secrete only when mistreated, while others, such as *Bombina* and particularly the American *Plethodon glutinosus*, produce a copious irritating or sticky secretion when handled. Closely related species may differ considerably in their secretions. Brazil and Vellard report that the South American *Ceratotophrys americana* has a virulent poison while the much larger and more brightly coloured *C. dorsata* possesses an innocuous skin secretion. Brightly coloured Amphibia are frequently not more poisonous than their dull coloured relatives, and some, such as the red-legged *Leptodactylus pentadactylus* may lack a poisonous secretion. Frequently the secretions are odorous, certain closely related forms of *Rana*, *Bufo* and *Hyla* being readily distinguished by their odour alone.

The skin of the larva differs from that of the adult in that the glands are unicellular and the epidermis consists of only two layers of cells. Larvae approaching metamorphosis and most perennibranchs have a thicker epidermis equipped with multicellular glands. The superficial layer of epidermis is periodically shed by the adults and usually in one place. The first shedding of the entire epidermis occurs normally at metamorphosis, but perennibranchs, such as *Cryptobranchius* shed their skin in one piece before they lose their external gills, and the larvae of some salamanders shed their skin in minute pieces during part of their aquatic life.

Pigmentation.—The coloration of Amphibia is due in part to a diffuse pigment distributed throughout the integument, but chiefly to a number of cellular elements of which three main types may be recognized: first, white cells which owe their colour to a dense deposit of guanine (a substance allied to the urates); secondly, the yellow cells which contain droplets of oil; and thirdly, the dark brown or melanin filled cells. White cells are often clumped together in small areas under the epidermis producing the white flecks on the back of many salamanders, or the white spots in some tree frogs. Other guanine-filled cells lie closely associated with the yellow and brown cells directly under broad areas of the epidermis and give the characteristic ground colour of these regions. Green is a mixed colour due to the blue rays of light reflected from the small guanine or "turbid cells" mixing with the yellow tone in the overlying yellow cells to produce a green. The blue reflections of the turbid cells are swamped by the white reflections of the subjacent tissues when the melanophores or dark cells are contracted. Brown is produced by the complete enclosure of the turbid cells by the expanded melanophores. The latter expand to surround the turbid cells when stimulated by cold, moisture and rough surfaces, or by hormones produced by the pars intermedia of the pituitary gland. The colour tone of a frog or toad at any one time may be due to either stimulations received through the skin or eyes or to the physiological (emotional) state of the individual.

Organs of Nutrition, Respiration, and Reproduction.—As these organs are only rarely used in defining natural groups of Amphibia they may be discussed here briefly. Amphibia are primarily carnivorous, only the larvae of the Salientia being more or less herbivorous in their diet. The intestine is therefore short, except in the tadpoles. The tongue is more developed in the primitive forms and may be rudimentary or absent in the aquatic species. The development shows that the urodele tongue arises out of two parts of which the hinder is homologous to the tongue of fishes, while the anterior and lateral part is a glandular fold which has been added to the first part during evolution.

Although the Amphibia have not evolved from the Dipnoans, they show many similarities in their venous and arterial systems. The heart of salamanders shows various modifications according

to the extent that the lungs are used in respiration. Many urodeles living near mountain streams have lost their lungs and respire entirely by their skins and well-vascularized throats. The entire family *Plethodontidae* is lungless. Many other salamanders use their lungs primarily as hydrostatic and not respiratory organs. Salamanders are mute or endowed with a very poor voice. Most Salientia have a larynx modified and equipped with vocal organs. Frogs call chiefly to attract mates in the spring.

Fertilization in the Amphibia may be external or internal. Most salamanders, except the *Hynobiidae* and *Cryptobranchidae*, are equipped with a spermatheca, a series of tubules in the roof of the cloaca where the sperm remain after copulation until the time of fertilization. In these salamanders the sperm mass is emitted by the males in the form of spermatophores, small tufts of sperm attached to a gelatinous base. Courtship in the salamanders is primarily directed towards exciting the female sufficiently to ensure her picking up the spermatophore with the cloacal lips. The sperm then make their way into the spermatheca by their own efforts. The Gymnophiona are equipped with a protrusible cloaca which is used as an intramittent organ. The male American liopelmid frog, *Ascaphus*, has a movable extension of the cloaca. In these forms fertilization is internal, as well as in certain little-known African frogs which have no special apparatus for transmitting sperm. The gonads are variously modified in different groups permitting a greater freedom of the seminal ducts from the kidneys. In *Bufo* a rudimentary ovary, Bidder's organ, is found in front of the testis and when the latter is removed it develops into a functional ovary. Sex reversal has also been recorded in both frogs and salamanders. (See SEX.)

Life History.—Most Caudata and Salientia lay their eggs in the water, where they hatch into larvae or tadpoles destined to live a more or less extended period in this element before metamorphosing into terrestrial adults similar to their parents. The larval state seems to be an old inheritance of the Amphibia handed down from their crossopterygian fish ancestors. Even the most primitive Amphibia underwent a metamorphosis, for the fossilized remains of both larval labyrinthodonts and branchiosaurs are known.

Metamorphosis represents a period of tremendous change in both the morphology and physiology of Amphibia. It is marked by such external changes in urodeles as the reduction of the external gills, the loss of the tail fin, the shedding of the larval skin, the formation of eyelids, etc. But fundamental changes in skull form and throat musculature take place. In Salientia metamorphosis is indicated by a freeing of the forelimbs by autolysis of local areas in the operculum, by radical changes in the shape and structure of the head, and by absorption of the tail. One of the recent achievements of physiology has been the demonstration that the changes of metamorphosis are produced by the thyroid hormone, or at least this hormone working in conjunction with that of the anterior lobe of the hypophysis. A review of the physiology of development cannot be given here, but reference may be made to the summaries of Remy ("Les sécrétions internes et les métamorphoses," *Amer. Sci. nat. Zool.* [10], vii.), Uhlenhuth ("The internal secretions in growth and development of amphibians," *Amer. Nat.*, 1921) and Allen ("Influence of the hypophysis upon the thyroid gland in amphibian larvae," *Univ. Calif. Publ. Zool.*, xxi, 1927). (See ENDOCRINOLOGY.)

Certain groups of urodeles, such as the *Cryptobranchidae*, *Sirenidae* and *Proteidae*, fail to metamorphose. This phenomenon appears as a variation in the life history of many urodeles, particularly in those species passing their larval period in cold water. Neoteny in the latter case is due to the failure of the thyroid to function, but the causes of arrested development in the case of groups unknown as metamorphosed individuals is more complex. In considering the relations of the perennibranchs, it is important to compare their organization with that of the larvae of other groups, not with that of the adults. Neoteny is not a new development in the Amphibia. It is found even in the Permian *Dwinosaurus*.

Some salamanders and many tropical Salientia produce large yolked eggs which they usually lay on land, although a few re-

tain them within the oviducts until the young are born more or less fully developed. Only two frogs are viviparous and both are rare East African species (*Nectophrynoides tornieri* and *N. vivi-para*). The breeding habits of the Amphibia are often elaborate and it is noteworthy that one may trace within the group a gradual evolution in many of the instincts associated with courtship and egg laying.

The larvae of the Amphibia frequently exhibit specializations which are of phylogenetic or at least taxonomic importance. The larvae of the marsupial frog and its allies possess enormous bell-shaped gills. All brevicipitid tadpoles, except those of certain South African genera which probably had an independent origin, have the same toothless, protrusible buccal apparatus. Where the life history is very specialized both larval modifications and breeding habits will tend to indicate the relationships of the forms. Thus, only *Protopipa* and *Pipa* carry their eggs in individual dermal chambers on the maternal parents' back; *Phyllobates* and *Dendrobates* are the only genera which transport to the streams their unspecialized tadpoles on the males' back; *Cryptobatrachus*, *Cerathyla*, *Gastrotheca* and *Amphignathodon*, the only ones which carry their eggs in a single mass on their backs (either exposed or enclosed in a dermal fold). The genera in each of these groups differed one from the other in matters of dentition and, hence, according to earlier classifications, would not be considered closely related. But recently when both anatomical and life history data were considered in further detail it was recognized that each of these groups is in fact a natural one.

Geographical Distribution.—Distribution of the urodeles does not agree with that of the Salientia and the latter is unlike that of the coecilians, for each of these groups probably spread from different centres, were affected by different barriers, and subjected to diverse conditions of travel. The present distribution of the Amphibia gives evidence of former union of the northern continents. Cryptobranchid salamanders are found only in eastern Asia and eastern North America. Proteid salamanders are found only in Europe and North America. One genus of plethodontids, *Hydromantes*, is found only in the two latter regions. One genus of salamandrids, *Triturus*, is holarctic, although a closely related form has apparently managed to work its way south of the Sahara. *Rana* and *Bufo* have closely related species in North America, Europe and Asia. The present distribution of the Amphibia also necessitates an early Tertiary connection between North and South America, for the plethodontid genus, *Ensatina*, is now found in Argentina, also the bufonid toads have undergone an enormous adaptive radiation in the latter continent. The ranids and some brevicipitids of South America may have reached the continent after the present Panamanian connection was formed, but the occurrence of several endemic genera of the latter group would favour an early migration for this family as well. The present distribution of the *Pelobatidae*, *Bufo* and *Rana* apparently demands a land bridge between Asia and Africa during part of the Tertiary and possibly a direct connection with the Seychelles. Pelobatids are not found in Africa, but in Asia, some of the East Indies, Europe, and the Seychelles. The bufonid *Nectophryne* is found in the oriental region and the African rain forest. The African *Chiromantis* is closely allied to the oriental *Polypedates*. *Rana* must have been in Africa for some time, for it has split up into a number of endemic subgenera. Madagascar is frequently claimed to have derived its fauna directly from the oriental region. *Polypedates* is found in both regions. The Madagascan *Dyscophus* is closely allied to the Asiatic *Calluella*. But Madagascar lacks coecilians and *Bufo*. Its ranids and brevicipitids have undergone an extensive local specialization which would suggest isolation. Further, it possesses *Hyperolius*, *Megalixalus* and *Rana* in common with Africa. If these recent and aggressive genera have gained access to Madagascar without the aid of a land bridge it is highly probable that brevicipitid and ranid stocks may have done the same at an earlier period when other genera formed the dominant African fauna.

It is frequently claimed that the present distribution of the Amphibia affords some of the best evidence of the existence of

former land bridges in the southern hemisphere. Coecilians are tropicopolitan; pipid toads occur only in tropical Africa and South America. Hence, many zoogeographers would postulate a land bridge across the mid-Atlantic. There is good evidence that in the case of other primitive groups extensive migrations have occurred in the northern region without leaving any fossil remains. For example, one genus of liopelmids is found to-day in North-western United States, the other in New Zealand, and consequently liopelmids must have occurred in the intervening area at one time. Salientia do not make good or frequent fossils, but the occurrence of toothed bufonids ("leptodactylids") in Australia, Africa and South America has led Hewitt to assume a radiation of toads from the south to Asia and the two latter continents along three theoretical land masses existing in Mesozoic times. Such speculations have little in their support and it is far simpler to assume that all families of Amphibia, except the neotropical *Brachycephalidae*, arose in one of the northern continents and migrated south along existing continental land masses.

To-day ambystomids, sirenids and amphiurids are endemic to North America and may have originated there. The large family of *Plethodontidae* are found chiefly in that continent. Hynobiids are known only from Asia. Salamandrids have their headquarters in Europe, although Asia, North Africa and North America have received a few species. Discoglossids are palartic, pelobatids mainly holarctic. Bufonids, hylids, ranids and brevicipitids have a world-wide range, but exhibit certain remarkable lacunae in their ranges. Thus, hylids are not found in the Ethiopian region (with a single possible exception) nor in most of South-eastern Asia and the adjacent islands; ranids, except the modern genus *Rana*, are absent from South America and Australia. The latter also lacks brevicipitids, except in the north-east. Papua has an amphibian fauna essentially like North-eastern Australia. It possesses bufonids, hylids, ranids and brevicipitids, but no pelobatids. The bufonids have undergone an adaptive radiation in Australia, while the brevicipitids did the same in New Guinea.

Economic Value.—Toads are of great use to farmers as they are indiscriminate feeders on insect life. In cases of an insect plague toads feed on the dominant insect and tend to restore the balance of nature. Frogs and toads are used for food in many parts of the world, but successful frog farms are rare. Frogs require from two to five years to reach maturity, and large quantities of living insect food are needed during this period. Hence, in America almost the entire frog crop is obtained in the wild state.

Dried frogs and salamanders are used for medicinal purposes in various parts of the world, particularly in the Orient. Their value as a cure is chiefly psychological. Probably the greatest use of Amphibia to humanity is their martyrdom to science. Frogs and salamanders both in adult and young stages have long been recognized as ideal laboratory animals. Some of our most fundamental discoveries in developmental mechanics (See EXPERIMENTAL EMBRYOLOGY), endocrinology (*q.v.*) and general physiology (*q.v.*) have been made with amphibian material.

AMPHIBIAN PLANE: see AERONAUTICS and SEAPLANE.

AMPHIBOLE, an important group of rock-forming minerals very similar in chemical composition and general characters to the pyroxenes and, like them, falling into three series according to the system of crystallization (from the Gr. ἀμφίβηλος, "ambiguous"). They differ from the pyroxenes, however, in having an angle between the prismatic cleavages of 56° instead of 87°; they are specifically lighter than the corresponding pyroxenes, and in their optical characters they are distinguished by a stronger pleochroism and by a smaller angle of extinction on the plane of symmetry.

The amphiboles in their composition conform in general to the metasilicate formula $R''SiO_3$, and are usually classified as follows:—

ORTHORHOMBIC SERIES		
Anthophyllite	(Mg, Fe)SiO ₃	
Gedrite	(Mg, Fe)SiO ₃ —Al ₂ O ₃	
MONOCLINIC SERIES		
(a) Sesquioxide-free members		
Cummingtonite	(Mg, Fe)SiO ₃	
Grünerite	FeSiO ₃	
Tremolite	Ca, Mg ₃ (SiO ₃) ₄	
Actinolite	Ca(Mg, Fe) ₃ (SiO ₃) ₄	
(b) Sesquioxide-rich members		
Hornblende	Ca(Mg, Fe) ₃ (SiO ₃) ₄	
with variable	(Mg, Fe)SiO ₃ ·(Al, Fe) ₂ O ₃	
and	Na, Al(SiO ₃) ₂	
(c) Alkali amphiboles		
Glaucofan	Na(Al, Fe)(SiO ₃) ₂ ·(Mg, Fe)SiO ₃	
Crocidolite	NaFe ^{III} (SiO ₃) ₄	
Arfvedsonite	Na ₂ Fe ^{III} (SiO ₃) ₄	
Riebeckite	2NaFe ^{III} (SiO ₃) ₂ FeSiO ₃	
TRICLINIC SERIES		
Aenigmatite Group		
Aenigmatite	(Na, K, H) ₄ (Fe, Mg, Ca) ₉ (Fe, Al) ₂ (Si, Ti) ₁₂ O ₃₈	
Cossyrite	H ₄ Na ₄ Fe ₁₆ Fe ₂ '''(Si, Ti) ₂₂ O ₆₇	
Rhoenite	(Ca, Na ₂ , K ₂)Mg ₄ Fe ₂ '''Fe ₂ '''Al ₄ (Si, Ti) ₆ O ₃₀	

Though, as already stated, there is a close similarity in composition between the amphiboles and pyroxenes, the former are the more complicated and their nature less understood. Most amphiboles contain some alkalis, fluorine and water of constitution and do not with few exceptions crystallize from dry melts. Rhombic amphibole of composition MgSiO₃ (kupferite) has been obtained as an unstable phase by rapid cooling of a MgSiO₃ melt. The natural rhombic amphiboles always contain water and usually some alkali. Gedrite may contain up to 22% Al₂O₃.

The cummingtonite-grünerite group of monoclinic amphiboles appears to form a solid solution series. The magnesian end member has been prepared by rapid cooling of a MgSiO₃ melt and also by subjecting kupferite in the presence of water to a temperature of 375°–475°C. Cummingtonite occurs together with anthophyllite in anthophyllite schists and in parallel intergrowth with the latter mineral or with gedrite in pneumatolytically metamorphosed sediments as in Finland and Cornwall. Grünerite occurs in association with garnet and fayalite in the rocks known as eulysites and is a prominent constituent of the altered iron bearing rocks of the Lake Superior region.

A lime-magnesia amphibole of the composition CaMgSi₂O₆ has been prepared by rapid cooling of a melt of the composition 85% diopside 15% SiO₂, but in nature an amphibole of this composition is unknown. The sesquioxide-free amphiboles, tremolite and actinolite are most characteristic of metamorphosed calcareous sediments both thermal and dynamic, while in the metamorphosed igneous rocks—such as hornblende schists, the sesquioxide-rich hornblende is more common.

The hornblendes occurring as porphyritic crystals in some basalts, andesites and porphyrites, and known as basaltic hornblende are brown in thin slices and contain significant proportions of titanium. They are well known from the basalts of Bilin and

Schima (Czechoslovakia). They are distinguished by a very low optical extinction angle on the plane of symmetry. Hornblende is a common mineral of many types of igneous rocks as in granite, syenite and especially diorite; also in the crystalline schists.

The alkali amphiboles are distinguished by their very complicated composition and little is known of their constitution. They appear to form with hornblende a series of solid solutions which are represented by alkali amphiboles of intermediate composition. The alkali amphiboles may be subdivided broadly into two groups according to their composition, habit and mode of occurrence: an iron-poor light blue coloured group which are especially characteristic of the crystalline schists and an iron-rich dark blue coloured group which occur as prominent constituents of alkaline igneous rocks.

The first group is prominently represented by glaucophane and its alumina-rich relative gastaldite, while the second group is represented by the arfvedsonite-riebeckite series of amphiboles.

The arfvedsonite-riebeckite series occur in the alkaline igneous rocks such as nepheline syenite, tinguaita and phonolite. Riebeckite was first described from the granites of the island of Socotra. To be classed here is the hastingsite of the nepheline syenites of Ontario. Crossite, an alkali amphibole in the crystalline schists of Berkeley, California, is distinguished by possessing an optic axial plane normal to the plane of symmetry. Barkevikite, related to arfvedsonite is a brown pleochroic amphibole originally described from Barkevik (Norway).

The three minerals of the aenigmatite group, viz., aenigmatite, cossyrite and rhoenite are usually classed as triclinic amphiboles.

See also HORNBLLENDE and TREMOLITE.

(C. E. T.)

AMPHIBOLITE, in petrology the name given to a grey, green or black, typically non-schistose rock consisting mainly of amphibole and a feldspar of the plagioclase group, the use of the term being restricted, however, to rocks of metamorphic origin. The term may be contrasted with hornblende schist, which is of identical composition but possesses a well-defined schistose structure as compared with the granoblastic unfoliated structure of the amphibolite. As is the case with most petrological terms the exact connotation is not very strictly defined, and some authors reserve the term hornblende schist for schistose rocks built up essentially of amphibole. As accessory constituents may be noted a red lime-magnesia-iron garnet, epidote, zoisite, green pyroxene, scapolite, biotite, etc.

The commonest amphibole is the aluminous monoclinic hornblende. Other varieties, however, occur, such as tremolite, actinolite, the soda amphibole glaucophane and, more rarely still, crossite. The magnesia-iron amphiboles of the cummingtonite-grünertite series, and the rhombic amphiboles anthophyllite and gedrite form essential constituents of certain amphibolites. The usual plagioclase feldspar is an andesine or labradorite; in this zoning and lamellar twinning are often less marked than in the feldspars of igneous rocks.

The amphibolites are typical rocks of the metamorphic group and as such attain a large development in all regions of crystalline schists and gneisses as in the old preCambrian shields and in metamorphic areas of later date. They occur principally in stocks or bosses representing basic igneous intrusions, or as long, narrow strips intercolated among outcrops of other metamorphic rocks. Genetically they fall into two groups, the ortho-amphibolites, which are transmuted igneous rocks, and the para-amphibolites, the metamorphic representatives of sedimentary rocks. The former are much the more common, and of these the greater number are derived without significant change in bulk composition from gabbros and dolerites. Igneous rocks containing much augite pass under the conditions prevailing in regional metamorphism where shearing stress is dominant into rocks of this kind, the pyroxene being converted to amphibole often with separation of iron ores and sphene. From more alkaline basic rocks the soda amphibole, glaucophane, is produced.

Plagioclase feldspar is recrystallized with or without separation of some of the anorthite molecule as epidote or zoisite according to the grade of metamorphism imposed. The rock may thus be

completely transformed into a granoblastic aggregate of new-formed minerals with entire loss of all igneous textures. Frequently, however, this transformation is only partial, and examination of a large number of specimens reveals a series of intermediate or transitional stages, proving conclusively the nature of the processes at work.

The sedimentary amphibolites or para-amphibolites, less common than those above described, are frequent in some districts, such as the northern Alps, southern highlands of Scotland, Green mountains, U.S.A. Many of them have been ash-beds, and their conversion into hornblende-schists follows exactly similar stages to those exemplified by basic crystalline igneous rocks. Others have been greywackes of varied composition with epidote, chlorite, feldspar, quartz, iron oxides, etc., and may have been mixed with volcanic materials, or may be partly derived from the disintegration of basic rocks. When they are most metamorphosed they are often very hard to distinguish from igneous hornblende-schists; yet they rarely fail to reveal signs of bedding, pebbly structure, sedimentary banding and gradual transition into undoubtedly sedimentary types of gneiss and schist.

Impure dolomitic limestones yield on metamorphism para-amphibolites strikingly similar to some ortho-amphibolites. By mutual reaction of chlorite, kaolin, calcite and dolomite amphiboles and plagioclase feldspars are produced. The original nature of these highly altered rocks, however, is frequently displayed in the rapid variation in mineral composition followed across the strike, corresponding to initial inhomogeneity of the original sediment. Amphibolites of this type are common in the Haliburton-Bancroft area of Ontario, where they occur, together with ortho-amphibolites, as enclosures in the Laurentian gneiss.

(C. E. T.)

AMPHIBOLOGY or **AMPHIBOLY**, in logic, a verbal fallacy arising from ambiguity in the grammatical structure of a sentence (Aristotle, *Organon*, *Soph. El.*, ch. iv.). It occurs frequently in poetry, owing to the alteration for metrical reasons of the natural order of words; Jevons quotes as an example Shakespeare, *Henry VI.*: "The duke yet lives that Henry shall depose." The success of ancient oracles was largely due to skill in amphibology.

AMPHICTYONY, an association of ancient Greek communities centring in a shrine (from the Greek *ἀμφικτύονες*, "dwellers around"). The association primarily comprised neighbours, though the Delphic amphictyony came to include distant communities. Neighbouring communities chose the sanctuary of some deity at which to hold their periodical festival for worship and their fair for the interchange of goods. The Delian amphictyony reached the height of its splendour early in the 7th century B.C. The "Hymn to the Delian Apollo," composed about that time, celebrates the gathering of the Ionians at the shrine of their god on the island of Delos, to worship him with music, dancing and gymnastic contests. Peisistratus, taking possession of Delos, seems to have used the sanctuary as a means of extending his political influence. When, after the great war with Persia, the Aegean cities, under the leadership of Athens, united in a league (477 B.C.), they chose as its centre the temple of the Delian Apollo. How far the institutions of the Delian confederacy were based upon the amphictyonic organization cannot be determined.

The removal of the Treasury to Athens in 454 B.C. deprived Delos of political importance. In 426 B.C. the Athenians instituted a great festival to be held under their presidency every four years (Thuc. iii. 104). At the end of the Peloponnesian War Athens was deprived of Delos, but she appears to have regained control after the victory of Cnidus (394 B.C.). The affairs of the temple were managed by a board of five Athenian amphictyons, assisted by some Delian officials.

Far more famous is the Delphic amphictyony. It was originally composed of 12 tribes dwelling round Thermopylae—the Thes-salians, Boeotians, Dorians, Ionians, Perrhaebians, Magnetes, Locrians, Oetaeans, Phthiotes, Malians, Phocians and Dolopians. The name of the council (*Pulaia*) and of one set of deputies (*pulagorai*), together with the importance of the temple of Demeter at Anthela, near Thermopylae, suggests that this shrine was

the original centre of the association. How and when Delphi became the centre is uncertain. The council of the league included deputies of two different kinds—*pulagorai* and *hieromnemones*. The latter were 24 in number, two from each tribe. Originally made up of neighbours, the league in time admitted the Dorians of the Peloponnese and the Athenians (as Ionians). After the second Sacred War, Macedon took the place of the Phocians and the Delphians partially displaced the Perrhaebians and Dolopians.

In the following century the Aetolians gained such dominance in the amphictyony as to convert the council into an organ of their league. They were never formally admitted to membership, but maintained their supremacy in the council by controlling the votes of their allies. A few minor changes were introduced under the supremacy of the Roman republic; Augustus increased the number of votes to 30 and distributed them according to his pleasure. In the age of the Antonines the association was still in existence.

The *hieromnemones* of the Thessalians, who held the presidency, were elected, but the office was ordinarily, as at Athens, filled by lot. As a rule they were renewed annually. Each *hieromnemon* was accompanied by two *pulagorai*, elected semi-annually. On one occasion Athens is known to have sent three. The *hieromnemones* were formally superior, but being usually mediocrities, readily became the tools of the *pulagorai*, who were orators and statesmen. The latter are rightly given credit for the acts of the council; it was the *pulagorai* who set a price on the head of the traitor Ephialtes (Herod. vii. 213), and who, on the motion of Themistocles, rejected the proposition of Lacedaemon for the expulsion of the States which had sided with Persia. The *pulagorai* had a right to propose measures and to take part in the deliberations. The *hieromnemon*, however, cast the vote of his community, though in the record his two *pulagorai* were made equally responsible for it. The inference is that the vote was determined by a majority of the three deputies.

The amphictyons met both in the spring and in the autumn at Delphi and at Thermopylae. The meeting at Thermopylae followed that at Delphi. The primary function of the council was to administer the temporal affairs of the two shrines. The duty of the *hieromnemones* was to inspect periodically the sacred lands, to punish those who encroached, and to see that the tenants rendered their quota of produce; and the council held the States responsible for the performance of such duties by their deputies. Another task of the council was to supervise the Treasury, to protect it from thieves, to increase the capital by investment and to control the expenditure. We find it contracting for the rebuilding of the Delphic temple after it had been destroyed by fire, adorning the interior with statues and pictures, inscribing the proverbs of the Seven Sages on the walls, bestowing crowns on benefactors of the god, preparing for the Pythian games, awarding the prizes and issuing coins. A law of great interest imposed an oath upon the members of the league not to destroy an amphictyonic city or to cut it off from running water in war or peace; but to wage war upon those who transgressed this ordinance, and to punish any others who sought to injure the god. In this regulation, which was intended to mitigate the usages of war among the members of the league, we have one of the origins of Greek inter-state law. It was also unlawful to levy tolls on pilgrims to the shrines. Other regulations were made to secure peace at the time of the festival, and occasionally the council was called upon to arbitrate in a dispute; but no provision was made to compel arbitration.

For the enforcement of such laws it was necessary that the council should have judicial power. As jurors the deputies took an oath to decide according to law or, in cases not covered by law, according to their best judgment. The earliest known penalty inflicted was the destruction of Crisa for having levied tolls on pilgrims. This offence was the cause of the first Sacred War. The second and third Sacred Wars, fought in the 4th century B.C., were waged by the amphictyons against the Phocians and the Amphissaean respectively for trespassing on the sacred lands. The council fined the Dolopians for piracy, and the Lacedaemonians for having occupied the citadel of Thebes in time of peace.

The judgments of the council were sometimes considered unfair, and were defied by the States affected. The Lacedaemonians refused to pay the fine above mentioned; the Athenians protested against the treatment of Amphissa, and were slow in accepting the decisions given under the influence of Macedon. The inability of the council to enforce its resolutions was chiefly due to its composition; the majority of the communities represented were even in combination no match for individual cities like Athens, Sparta or Thebes. As in the League of Nations (*q.v.*), the support of the "great powers" was necessary if more than moral influence was to be employed. But the moral influence was usually powerful.

In addition to these associations there was an amphictyony of Onchestus and an amphictyony of Argos of which Epidaurus and Aegina were members.

AMPHILOCHUS (ām-fil'ō-kus), in Greek legend, a famous seer, son of Amphiarus and Eriphyle and brother of Alcmaeon. According to some, he assisted in the murder of Eriphyle, which, according to others, was carried out by Alcmaeon alone. He took part in the expedition of the Epigoni against Thebes and in the Trojan war. After the fall of Troy he founded, in conjunction with Mopsus, another famous seer, the oracle of Mallos in Cilicia. The two seers afterwards fought for its possession, and both were slain in the combat. Amphilocheus is also said to have been killed by Apollo (Strabo xiv. 675, 676). According to another story, he returned to Argos from Troy, but, being dissatisfied, left it for Acarnania, where he founded Amphilocheian Argos on the Ambracian gulf. He was worshipped at Oropus, Athens and Sparta.

See Strabo xiv. pp. 675, 676; Thucydides ii. 68; Pausanias i. 34, iii. 15.

AMPHINEURA, group of marine invertebrate animals constituting a class of the Mollusca (*q.v.*), the majority with a shell of eight transverse plates. A much smaller number are devoid of a shell and have the general appearance of worms. Up to the present upwards of 120 genera of these animals have been described. They are all sedentary, slow-moving creatures usually of insignificant size, and are generally found in shallow water. Until recent years it was customary to regard the class as divisible into two orders, the shell-bearing Chitons or Polyplacophora and the worm-like Solenogastres or Aplacophora. The Chitons are divided into three suborders according to the structure of the shell, and the Solenogastres into two suborders, the Neomeniomorpha and Chaetodermomorpha. Some zoologists, however, regard the Solenogastres as more closely allied to certain groups of primitive worms (Platyhelminia, Archiannelida) than to the Mollusca. J. Thiele (1925) has accordingly removed them from the Mollusca, in which they were placed by Spengel and Ray Lankester. The name Amphineura, which was used to designate the Chitons and Solenogastres collectively, is therefore abandoned by Thiele and the older name Loricata has been revived for the Chitons, which are still treated by Thiele as a class of the Mollusca. In this article the Solenogastres are included in the Mollusca and the unity of the Amphineura is upheld; but the question of the relationships of the Solenogastres cannot be regarded as finally settled. (See below.)

The Chitons are elongate, rather flattened animals, rarely exceeding a few inches in length. *Cryptochiton stelleri* attains a length of 20cm., and the smallest forms barely exceed half an inch when fully grown. The overlapping plates of the shell give them the appearance of wood-lice, a comparison perhaps more accurate than that involved in the German name *Käferschnecke*, or "beetle-snails." The outer covering of the animal constitutes the "mantle" on the upper surface and sides. On the lower surface it forms the solid and muscular foot. (See MOLLUSCA.) The cells of the mantle secrete the eight calcareous plates of the shell. In most genera of Chitons the separate valves are articu-

lated together, though with enough freedom to enable the animal to roll up into a ball like a wood-louse. The plates are pierced by a number of branching canals through which nerves pass to end on the surface of the shell in peculiar sense organs known as "shell-eyes." In some forms the shell becomes covered by the mantle. This is well seen in the large *Cryptochiton stelleri* of the north-east Pacific. The mantle also secretes horny or calcified

BY COURTESY OF THE LINNEAN SOCIETY OF SOUTH WALES

FIG. 1.—THE OVERLAPPING PLATES OF THE SHELL OF CHITON FUNEREUS, ONE OF THE SHELL BEARING AMPHINEURA

spicules. These are found at the edge of the mantle (girdle), where it projects beyond the shell. In *Tonicia* and other genera the spicules are so large and numerous that they give the animal a rough and shaggy appearance. The cavity of the mouth contains the radula (see MOLLUSCA) or rasping tongue. The alimentary canal extends in a straight line from the mouth to the anus, which is situated at the posterior end of the body. It receives the ducts of the mucous and salivary glands and of the liver. The heart occupies a position in the middle line at the posterior end. A single aorta leads the blood from the heart, and it is eventually collected for oxygenation into two large cavities (sinuses). From these it passes to the gills, which project from the adjacent body-wall into the cavity formed by the edge of the mantle, where it overhangs the sides. The gills vary in number from four to 80. There are two kidneys, one on each side of the body. Their external apertures are at the posterior end of the body, and at their inner end they open into the pericardium (the cavity surrounding the heart). The nervous system consists of four main nerve trunks joined by transverse commissures and, unlike the main nerve cords of Gastropoda and other molluscs, is largely without ganglia. The sexes are separate in the Chitons. The ovary and testis have no communication with the pericardium as they have in the Solenogastres. The ova and spermatozoa are passed to the exterior by a pair of gonaducts.

Regarded as molluscs, the Solenogastres are mainly characterized by the loss of the shell, the substantial reduction or loss

of the foot, and the fact that there are no separate generative ducts. The gonad (ovary or testis) opens into the pericardium and the ova or spermatozoa are discharged by the kidneys. The gills are concentrated in a posterior cavity (cloaca). In *Neomenia* and its allies there is, on the under surface of the body, a groove which is interpreted as the line of junction between the two edges of the mantle which have grown round the sides. In the *Chaetodermatidae* this groove is absent, and the animal is entirely cylindrical.

The embryological development of the Solenogastres is still imperfectly known; but, as far as it has been studied, it is held to endorse the conclusion that these animals are more nearly allied to certain groups of worms than to the Mollusca.

As a class the Amphineura have a world-wide distribution; but, while some genera (e.g., *Lepidopleurus*) are found in nearly

all seas, others have a more localized occurrence. The Chitons are found in a fossil state in the Ordovician. Their evolutionary history has been uneventful, no very marked departure from the main type of shell-structure being recorded. The Solenogastres have not so far been recognized as fossils. Both the Chitons and the Solenogastres are sluggish animals, creeping slowly about to no great distance. The Chitons are found on or under rocks and stones. The chemical constitution of the rock is of small importance in determining the occurrence of these animals. They prefer a smooth surface and are usually found on rocks that weather to such a condition. Ashby found the greatest numbers on pure granite, "counting over 70 specimens of *Ischnoradsia* on a single rock no larger than a dinner plate." *Neomenia* and its allies live on corals and hydroids, while *Chaetoderma* prefers muddy and oozy bottoms. Some members of the class are found at very great depths, e.g., *Leptochiton benthus* in 2,300 fathoms ("Challenger"); but most of them live in shallow littoral waters. The Chitons are mainly herbivorous and browse on the Algae that adhere to rocks. The members of the Neomeniidae which live on corals and hydroids feed on those organisms and are thus carnivorous. Free-living Neomeniomorpha such as *Proparamenia* are probably more aggressive and active in their feeding-habits. *Chaetoderma* and its allies feed on minute organisms such as *Protozoa*, etc.

The lack of satisfactory evidence as to the development of the Solenogastres makes it difficult to assess their relationships. The structural peculiarities on which Thiele, Odhner and others have relied in removing these animals from the mollusc lead us to believe that their affinity with the Chitons may not be so close as was formerly believed. But a critical test of their relationships can only be provided by a study of their development.

For the relationship of the Amphineura to the other groups of Mollusca, see MOLLUSCA.

AMPHION and ZETHUS, in Greek mythology, the twin sons of Zeus by Antiope. When children, they were exposed on Mt. Cithaeron, but were found and brought up by a shepherd. Amphion became a great singer and musician, Zethus a hunter and herdsman. After punishing Lycus and Dirce for cruel treatment of Antiope (q.v.), they built and fortified Thebes, huge blocks of stone forming themselves into walls at the sound of Amphion's lyre. Amphion married Niobe, and killed himself after the loss of his wife and children (Ovid. *Metam.*, vi. 270).

AMPHIOXUS or LANCELET, a small, marine creature, neither fish nor worm, but something between the two, which is the simplest example of the Vertebrate type of structure. It was first discovered on the coast of Cornwall, and a preserved

specimen sent to Pallas, who was unacquainted with its lively movements, was described by him in 1774 as a slug, *Limax lanceolatus*. Couch rediscovered it in 1831, and his specimen was described and figured by Yarrell in 1836 under the title *Amphioxus lanceolatus* (*Brit. Fishes*, vol. ii.).

Characteristics.—The body of *Amphioxus* rarely exceeds 2½ in. in length. It is laterally compressed and tapered at each extremity. From end to end above the alimentary canal runs a solid, elastic rod, the notochord, which plays an important part in the animal's movements. On each side of it run powerful longitudinal muscles, which are divided up into chevron-like segments, the myotomes, like the muscle-flakes of a whiting. Above the notochord lies a nerve-cord, corresponding to the spinal cord of Vertebrates, and giving origin, like it, to alternate pairs of sensory and motor nerves, which, however, remain distinct, and do not unite to form complex structures like the spinal nerves, with their double roots, in Vertebrates. There is, moreover, no centralized brain in front, and no trace of paired olfactory, optic and auditory sense-organs and nerves. Jaws, teeth and other prehensile organs are lacking, as well as skull, vertebral cartilages and paired limbs or fins. The circular, contractile mouth lies at the back of a preoral depression, the buccal cavity, on the underside of the snout. This cavity is fringed behind and on each side by stiff processes or cirri, provided with a solid, jointed, internal skeleton. They are capable of spreading outwards, thus freely opening the buccal cavity, or of bending inwards, when they overlap the entrance with a protective grating. A circlet of true, sensitive tentacles lies just inside the circular mouth. The cheeks of the buccal cavity are beset inside with parallel ciliated ridges, which are offsets from a primary pair of dorso-lateral ridges, diverging behind around the mouth, and converging forwards to surround an asymmetrical cilio-glandular depression known as *Hatschek's pit*. The entire organ is known as the *wheel-organ*. Its ciliary action is directed backwards towards the mouth. The alimentary canal is described below.

Classification.—There has been a tendency to include *Amphioxus* within the Vertebrata as *Acrania*, but this procedure exaggerates the resemblances of *Amphioxus* to the Vertebrates, since in all the essentials of its life and organization, as distinct from superficial form, *Amphioxus* is much more intimately related to the Tunicata (*q.v.*), and constitutes with them a well-defined group, termed by Balfour Protochordata, the distinctive features of which lie in the feeding-mechanism described below. The differences between *Amphioxus* and the Tunicata are chiefly that *Amphioxus* retains its notochord and powers of locomotion throughout life, while in Tunicata these are mostly restricted to the larval stage, and the notochord itself is confined to the tail. *Balanoglossus* (*q.v.*), which in certain respects foreshadows *Amphioxus*, stands at a much lower plane of general organization,

and, with the Pterobranchia (*q.v.*), possesses mere rudiments of the characteristic notochord and neural canal. Thus the position of *Amphioxus* within the phylum Chordata is indicated by the following classification:

- CHORDATA
- I. Hemichordata { 1. Pterobranchia, *e.g.*, *Cephalodiscus*.
2. Enteropneusta, *e.g.*, *Balanoglossus*.
 - II. Protochordata { 1. Tunicata (=Urochorda).
2. Cephalochorda, *e.g.*, *Amphioxus*.
 - III. Vertebrata (=Craniata).

There are good reasons for regarding these three sub-phyla as marking successive stages in the progressive evolution of the Chordata, although in its possession of protonephridial excretory organs *Amphioxus* retains an archaic larval character (*cf. Actinotrocha*) which has been lost by all other Chordata.

In the latest revision of the Cephalochorda (Franz, 1922) two genera only are recognized, *Branchiostoma* (= *Amphioxus*) and *Asymmetron* (*see below*). Which is primitive? Franz decides in favour of *Amphioxus*; but, if their relationship with Tunicates is borne in mind, the unpaired gonads, the small size (9–10 mm.) at sexual maturity, and the frequent presence of a caudal appendage in *Asymmetron* enable us to recognize in this form a possible stage of transition from a neotenic Ascidian towards *Amphioxus*, the unsegmented caudal appendage (which supports a well-marked caudal fin in the pelagic larva) being a vestige of the Ascidian larval tail. The relations of the metapleural ridges and ventral fin-fold are consistent with this view, since it is generally admitted that the continuity of these structures in *Asymmetron*, though one-sided, is more primitive than the discontinuity in *Amphioxus*. The species of *Asymmetron* fall into two groups according to the presence or absence of the caudal appendage, the second group corresponding with the genus *Heteropleuron* of Kirkaldy; but the variations of a vestigial organ furnish an insecure basis for a definite division of the genus.

1. **ASYMMETRON**, Andrews (Tattersall).—Gonads on right side only; left metapleur distinct, the right continuous with the ventral fin.

A—with a distinct caudal appendage. Species: *lucayanum* (62–71 myotomes), Bahamas, Zanzibar to Philippines; *macriscadatum* (58–66), Florida; *caudatum* (60–64), Louisiade archipelago; *orientale* (63–69), Maldives.

B—without a caudal appendage. Species: *cultellum* (50–56 my., notochord unusually prominent behind), E. Africa to Philippines and E. Australia; *cingalense* (61–64), Ceylon; *parvum* and *agassizii* (68–70), Maldives; *maldivense* (70–76), Maldives and Laccadives; *bassanum* (70–78), S.W. Australia; *hectori* (84–85), New Zealand.

2. **AMPHIOXUS**, Yarrell (= *Branchiostoma*, Costa). Gonads in paired series; right and left metapleura ending symmetrically

behind the atriopore; no caudal appendage. Species: *lanceolatus* (58–62 my.), European coasts; *caribaeus* (57–60), Atlantic coasts of America; *haeckelii* (59–61), Ceylon; *belcheri* (63–66), E. Africa to Japan and Queensland; *californiensis* (64–69), California; *indicus* (69–71) (snout elongated), Indian Ocean; *capensis* (74–76), S. Africa; *elongatus* (77–80), Pacific coast of S. America.

Habits.—*Amphioxus* burrows in loose sand, into which it dives with amazing rapidity. It projects its snout above the surface, and remains perfectly still unless disturbed, when it darts out of the sand, gyrates wildly about in zig-zag fashion for a few seconds, and then plunges head-first in again. Except for these brief moments of activity, its habits are as sedentary as those of a fixed Ascidian. *Asymmetron* has similar habits, but *A. lucayanum* appears to be actively pelagic at night.

Feeding Mechanism.—*Amphioxus* agrees with the Tunicata, and differs from all other Chordata, in certain characteristic modifications of the front part of the alimentary canal or pharynx for the collection of minute floating organisms (microplankton) as food. The canal itself in *Amphioxus* runs straight from mouth to anus, the latter being situated ventrally a short distance from the posterior extremity of the body, to the left of the ventral fin (in Tunicata also the anus is left-sided, but dorsal). The long, dilated pharynx is succeeded by a narrow gastro-intestinal region, provided in front with a hepatic caecum projecting forwards on the right side. There is no distinct stomach. The entire side-walls of the pharynx, and the body-wall investing it, are pierced by a paired series of close-set U-shaped or tongue-barred gill-slits, each of which extends obliquely backwards, and is divided up into smaller perforations, firstly by fusion of the apex of the tongue-bar with the ventral wall of the

pair of epibranchial flaps (the subatrial ridges). This fusion is incomplete behind, leaving an aperture, the atriopore, situated ventrally, midway between pharynx and anus. The metapleurae are a pair of ventro-lateral ridges on the outer surface of the atrial wall.

The narrow roof and floor of the pharynx are grooved longitudinally. The ventral groove or endostyle is beset with rows of gland-cells, and between them runs a median tract of cells bearing long flagella. Its lateral margins are finely ciliated, and diverge in front to encircle the pharynx inside the mouth as a pair of peripharyngeal bands. These bands bend backwards dorsally and merge into the ciliation of the upper or epipharyngeal groove, which leads into the oesophagus. It is in fact the food-groove, and the rest of the pharynx is a collecting apparatus to supply it.

When *Amphioxus* is at rest, its mouth opens, and the cilia of its numerous gill-slits set up a current which flows steadily in through mouth and pharynx, and out through atrium and atriopore. At the same time the endostyle pours out a stream of mucilage, the greater part of which is flicked out of the groove right and left on to the side-walls of the pharynx, and is there swept upwards in the form of parallel longitudinal strings by the action of cilia coating the internal surface of the gill-bars. In this way the fenestrated walls of the pharynx are traversed by a moving succession of slimy threads. Food-particles entering with the water are sooner or later entangled in the mucilage and rolled upwards into the epipharyngeal groove which concentrates them and conveys them as a continuous food-rope backwards into the digestive part of the canal. The wheel-organ appears to assist this process in the buccal cavity by sweeping outlying particles on to the peripharyngeal bands.

Reproduction.—The sexes are separate. The gonads arise as pouches from the lower ends of the myotomes, and project into the atrium. At the breeding season the pouches burst, and the sexual elements pass through the atrium to the exterior, where fertilization takes place.

Development.—On account of its relative yolklessness, the fertilized egg of *Amphioxus* provides a typical example of total and regular segmentation, and of gastrulation by invagination. Notochord and neural canal (the latter enclosing the blastopore) are developed as in the lower Vertebrates. Paired mesoblastic somites arise as outgrowths, from the embryonic endoderm, and divide into the myotomes above and visceral elements below which unite to form the perivisceral coelom. A primitive tripartite arrangement of the coelom is recognizable, as in *Balanoglossus*, the myotomes and perivisceral elements being derivatives of the third primitive or trunk segment (MacBride). The first primitive segment is cut off from the blind extremity of the archenteron as a single vesicle, which divides into two, the right half expanding as the head-cavity, while the left, which acquires an opening to the exterior, becomes reduced to form Hatschek's pit. Its aperture is clearly homologous with the proboscis pore of *Balanoglossus* and the water-pore of Echinoderm larvae. It is surrounded in the larva by a peculiarly ciliated patch, known as the *preoral pit*, which subsequently develops into the wheel-organ of the adult. Goodrich has given good reasons for regarding this organ as equivalent to the anterior part, at any rate, of the Vertebrate hypophysis.

Exposing the organs which project into the atrial cavity (pharynx, intestine with liver, caecum directed forwards, row of gonads in each side-wall)

AFTER ANDREWS, "AN UNDESCRIBED ACRANIATE ASYMMETRON LUCAYANUM" IN "STUDIES FOR THE BIOLOGICAL LABORATORY OF JOHNS HOPKINS UNIVERSITY." BY PERMISSION OF THE JOHNS HOPKINS PRESS

FIG. 2.—DEVELOPMENT OF THE CAUDAL APPENDAGE OF ASYMMETRON LUCAYANUM BY ATROPHY OF THE PRIMITIVE CAUDAL FIN OF THE LARVA
A. Larva of 6 mm. with 22 gill-slits, no caecum and atrium unclosed ventrally
B. Immature specimen with 27 gill-slits, small caecum and closed atrium
C. Mature adult of 14 mm. with 28 gonads

Note the incipient development in C of a secondary caudal fin in the postanal region of the myotomes representing normal "caudal fin" of Amphioxus

slit, and then by subdivision of the half-gill-slits into stigmata by outgrowth of synapticulae from the tongue-bars. The edges of all the perforations are strongly ciliated and lash outwards through the body-wall. To protect the fenestrated walls from injury, the whole pharyngeal region is sunk beneath the general level, and enclosed within a peribranchial chamber or atrium by downgrowth of the muscular body-wall and ventral fusion of a

Amphioxus hatches at about the eighth hour after fertilization as a ciliated embryo, with the neural folds, notochord and first few mesoblastic somites established, but without mouth or anus. The ciliated embryo elongates rapidly with the formation of additional somites, and at about the 36th hour passes into the first larval stage, characterized by perforation of the mouth, first gill-slit and anus. This stage is curiously asymmetrical, the mouth and single gill-slit being situated opposite one another to left and right. The mouth becomes enormously distended along the left side, while new gill-slits arise on the right side up to as many as 14. Subsequently (metamorphosis stage) the last six of these, as well as the first one, close up, and the remainder rotate below to their permanent position on the left side, while a new series arises above the first to replace it on the right. At the same time the mouth rotates forwards to a median position.

Various theories have been put forward to account for this temporary distortion. The present writer suggests that it is the consequence of a secondary reduction of yolk in the egg, accompanied by premature hatching, which has entailed the improvisation of a temporary feeding mechanism, the basis of which appears to be the enlargement and special ciliation of the mouth and an adaptation of the club-shaped gland for the supply of mucilage.

AFTER WILLEY

FIG. 4.—ANTERIOR REGION OF TWO PELAGIC LARVAE OF *A. LANCEOLATUS* Showing the large left-sided mouth with its ciliated margin and the opposite series of simple primary gill-slits

Of great interest are the origin of the endostyle as a V-shaped loop of the peripharyngeal band, thus recalling the adoral band of Echinoderm larvae, and the development immediately behind the endostyle, of the club-shaped gland, with two successive internal orifices on opposite sides of the endostyle, and a single external orifice below the left-sided mouth. Willey regarded this gland as a modified gill-cleft. The present writer identifies it with certain pharyngeal glands of Appendicularians, and interprets all of them as highly modified vestiges of the epicardium or budding-organ of Tunicata (*q.v.*).

Evolution.—If these views are correct, *Amphioxus* must have been derived from sessile ancestors of a primitive Ascidian stock, and its elongated form is the result of loss of fixation and retention of larval habits, modified by secondary adaptation to an arenicolous life. We have already seen that *Asymmetron* retains a caudal appendage which can be little else than a remnant of the Ascidian larval tail, and this accords with its possession of unpaired gonads as in Ascidians. The secondary symmetrization of the gonads in *Amphioxus* is paralleled in Ascidians themselves (Stolidobranchia). The main axis of Chordate evolution may thus be regarded as a line of sedentary plankton-feeding organisms, which began with an external apparatus of ciliated tentacles and food-grooves, and ended with an endopharyngeal mechanism of gill-slits and endostyle. From this Pterobranch-Ascidian line *Balanoglossus*, *Amphioxus* and the Appendicularians have been given off at different levels as successive paedomorphic offshoots. The line may be carried still farther back to the primitive stalked Echinoderms, to inheritance from which we must ascribe such features as the larval form of *Balanoglossus* (*Tornaria*), Hatschek's pit and the V-shaped endostyle of *Amphioxus*. Assuming that the ancestral Echinoderm handed on to its Hemichordate descendants a primitive type of Dipleurula larva, the Protochordate tadpole may readily have been derived from it by the substitution of muscular for ciliary means of progression. The adoral band may thus have been the forerunner of the endostyle, and the circumoral ciliated band, with its underlying nervous system, of the ciliated neural folds of Vertebrates, which at the outset have identical relations to mouth and blastopore.

That the Vertebrata have been derived from Protochordata, and not vice versa, is shown by the retention in Vertebrate embryos of unequivocal remnants of the Protochordate feeding mechanism of endostyle and tongue-barred gill-slits, as shown by the details of development of the thyroid and thymus glands.

AMPHIPODA, an order of Crustacea (*q.v.*), with the body usually laterally compressed, the second and third pairs of thoracic appendages generally modified as prehensile organs and the three anterior abdominal appendages many jointed. The best-known form is the fresh-water shrimp (*Gammarus*), common in nearly all parts of the world.

AMPHIPOLIS (mod. YENI KEUI), ancient city of Macedonia, on the east bank of the River Strymon, where it emerges from Lake Cercinitis, about 3m. from the sea. Originally a Thracian town, known as 'Envéa 'Oðoi ("Nine Roads"), it was colonized by Athenians with other Greeks under Hagnon in 437 B.C., previous attempts—in 497, 476 and 465—having been unsuccessful. In 424 B.C. it surrendered to the Spartan Brasidas without resistance, through the negligence of the historian Thucydides, who was with the fleet at Thasos. In 422 B.C. Cleon led an unsuccessful expedition to recover it; both he and Brasidas were slain. It was to have been restored to Athens by the Peace of Nicias (421) but remained long independent. In 357 Philip of Macedon occupied it in spite of Athenian opposition. The importance of Amphipolis was due to its command of the bridge over the Strymon, and the route from northern Greece to the Hellespont; it was also a depot for the gold and silver mines of the district, and for ship-timber. Under the early empire it became the headquarters of the Roman governor of Macedonia, though recognized as independent. Many inscriptions, coins, etc., have been found here, and traces of ancient fortifications and a Roman aqueduct are visible. (See S. Casson, *Macedonia, Thrace and Ilyria* [1926], and Pauly-Wissowa, *s.v.*).

AMPHISBAENA is the name given to the main genus of a family of worm-shaped lizards, most of which inhabit the tropical parts of America, the West Indies and Africa. The commonest species in South America and the Antilles is the sooty or dusky *A. fuliginosa*. The body of the amphisbaena, from 18 to 20 in. long, is of nearly the same thickness throughout. The head is small, and there can scarcely be said to be a tail, the vent being close to the extremity of the body. The animal lives mostly underground, burrowing in soft earth, and feeds on ants and other small animals. The name, which implies that the animal can move in either direction, was applied to a serpent in Greek mythology; and has been transferred to the lizard by zoologists because owing to the superficial resemblance between the head and tail the Brazilian natives call it the snake with two heads and believe that it can reverse the direction of its motion.

AMPHITHEATRE, a building, primarily for entertainments, in which the seats for the spectators surround the stage or arena. It is differentiated from the stadium (*q.v.*) by the fact that its shape approximates an ellipse. The amphitheatre was early developed in the Italian peninsula as the logical building for the local gladiatorial combats. The early amphitheatres were built of wood and were strictly temporary and it was only in the last century of the Republic that permanent amphitheatres of stone were erected (Pompeii *c.* 80 B.C.). In Rome an amphitheatre with a stone enclosing wall and wooden seats was built in 29 B.C. by C. Statilius Taurus.

But it is the earliest great Roman amphitheatre, the Flavian, or Colosseum, that has remained the outstanding and the largest example of the type. It was built by Vespasian and Titus upon the site of part of Nero's "Golden House." The Colosseum, as it now stands, was completed only after the great fire of A.D. 217, when the present upper storey, till then of wood, was added. The dimensions of this amphitheatre are 615 by 510 ft. with an arena 281 by 177 feet. Its capacity is now estimated at about 50,000, the ancient Roman estimates, which varied from 80,000 to 100,000, being manifestly exaggerated. Other great examples of the ancient amphitheatre are: the Amphitheatre Castrense in Rome, built of brick, probably during the reign of Trajan; the amphitheatre at Pompeii already mentioned, 444 by 342 ft.; that at Capua, 557 by 458 ft.; that at Verona, 502 by 403 ft., probably of the time of Diocletian; that at Pozzuoli, 482 by 383 ft., particularly famous for the perfect preservation of its stage arrangements; and, outside of Italy, those at Nîmes and Arles in France; Pola in Istria; and Thysdrus in Africa, all of these of approximately the same size—between 400 and 500 ft. long and between 300 and 400 ft. wide. Besides these, fragmentary remains are found widely scattered throughout the Roman empire. In England, at Silchester, in Hampshire, there is an example in which the seats were placed largely on banked up earth.

In the typical Roman amphitheatre the arena was usually raised above an elaborate structure containing cells for wild beasts, storage room, connecting passages and rooms for gladiators, all ingeniously arranged to connect by means of many trap doors with the arena above (*see* illustration of Pozzuoli). Around this arena, and separated from it by a high wall, arose the seats of the spectators. These were divided by passageways running around the amphitheatre into several sections (*maeniana*); the lowest, known as the podium, for state officials; the next reserved for the wealthy or the nobles; and those above for the rest of the populace. Each of these was divided into wedge shaped sections (*cunei*) by radial walks and from them many exits (*vomitória*) led down to the passages below the seats and so to the street. Apparently seats were always reserved, as they are usually carefully numbered; and tickets of clay bearing the seat numbers have been found. The seats were supported on walls running radially to the exterior between which the exit stairs were most ingeniously arranged so that the enormous crowds were distributed evenly to the exit arches which surrounded the ground storey. In addition, vaulted corridors ran elliptically around the outside, connecting the various radial elements; the arcaded exterior was, therefore, a necessary and logical expression of the construction.

In modern usage the word amphitheatre is sometimes used for

a theatre or concert hall whose seats surround the central area, as, for example, the Albert Hall, London, and both the new and the old Madison Square Garden in New York. Modern open amphitheatres also exist, particularly in connection with the sports of the United States, as, for instance, the Chicago "stadium" (cap. 100,000), Franklin Field, Philadelphia (cap. 83,000), the Yale "Bowl" at New Haven (cap. 80,000), the Baltimore "stadium" (cap. 78,000) and that at Los Angeles (cap. 75,000). The largest of all structures of this type, however, is that at Wembley, near London, which accommodates 25,000 persons under cover, 10,000 at the ringside and 91,500 standing, or a total of 126,500. Other amphitheatres have been built or projected on the continent of Europe.

AMPHITRITE, in mythology of ancient Greece, a sea-goddess, daughter of Nereus (or Oceanus) and wife of Poseidon. It was said that Poseidon saw her first dancing at Naxos among the other Nereids, and carried her off. She then fled from him over the sea, but was found by the dolphin of Poseidon, which was afterwards set among the stars. In works of art she is represented either enthroned beside him or driving with him in a chariot drawn by sea-horses or other fabulous creatures of the deep, and attended by Tritons and Nereids.

AMPHITRYON, in Greek mythology, son of Alcaeus, king of Tiryns. Having accidentally killed his uncle Electryon, king of Mycenae, he was driven out by another uncle, Sthenelus. He fled with Alcmena, Electryon's daughter, to Thebes, where he was cleansed from the guilt of blood by Creon, his maternal uncle, king of Thebes. Alcmena, who had been betrothed to Amphitryon by her father, refused to marry him until he had avenged the death of her brothers, all of whom except one had fallen in battle against the Taphians. Amphitryon accordingly took the field against the Taphians, accompanied by Creon, who had agreed to assist him on condition that he should slay the Teumessian fox which had been sent by Dionysus to ravage the country. The Taphians, however, remained invincible until Comaetho, the king's daughter, out of love for Amphitryon, cut off her father's golden hair, the possession of which rendered him immortal. Having defeated the enemy, Amphitryon put Comaetho to death and handed over the kingdom of the Taphians to Cephalus. On his return to Thebes he married Alcmena, who gave birth to twin sons, Iphicles being the son of Amphitryon, Hercules of Zeus, who had visited her during Amphitryon's absence.

The modern use of *Amphitryon* in the sense of a generous host is derived from Molière's comedy on the subject, iii. 5.

See Apollodorus ii. 54–62; Herodotus v. 59; Pausanias viii. 14, ix. 10, 11, 17; Hesiod, *Shield*, 1–56; Pindar, *Pyth.*, ix. 81.

AMPHORA, usually an earthenware vessel used by the ancient Greeks and Romans and so named from having a handle on each side of the neck (Gr. *ἀμφί*, on both sides; *φέρειν*, to carry). Amphorae either rested on a foot, or ended in a point so that they had to be fixed in the ground. The amphora was a standard measure of capacity among both Greeks and Romans, the Attic containing nearly nine gallons, and the Roman about six.

AMPLIATIVE JUDGMENTS or **PROPOSITIONS** are those in which something is affirmed that is not included in the definition or connotation of the subject. When the predicate merely unfolds or analyses the meaning of the subject, the proposition is called "explicative." (When the predicate is a *genus* or *differentia* of the subject, the proposition is explicative; if the predicate is a *proprium* or *accidens* the proposition is ampliative. *See* PREDICABLES.) Instead of "ampliative" the terms "augmentative" and "synthetic" are also used; and the terms "analytic" and "verbal" are sometimes used instead of "explicative." (*See* ANALYSIS and LOGIC.)

AMPLIFICATION. In radio communication amplification may be considered as a magnification or enlargement of energy which takes place in an electrical circuit. It is a function by which the intensity of the electrical variations in the output circuit are increased without altering their wave forms. Amplification is essentially a relay action. In radio reception, the comparatively weak signal voltages impressed on a vacuum tube *amplifier* produce in the output circuit a correspondingly increased amount of power which is drawn from the "B" battery or other source of power in the plate circuit. The *amplification factor* is a number which expresses the magnitude of this effect.

AMPLIFICATION FACTOR OF A VACUUM TUBE, a quantity which is used to express the relative effects of the grid voltage and plate voltage in affecting the plate current of a vacuum tube. The amplification factor is the change in plate potential divided by the negative change in grid potential under the condition that the plate current remains unchanged. As most precisely used, the term refers to infinitesimal changes in the potentials as indicated in the defining equation. Amplification

$$\text{factor } \mu = -\frac{de_p}{de_g} \cdot i_p = \text{constant}.$$

AMPLIFIERS. The function of an amplifier is to increase the intensity of electrical or other fluctuations without seriously altering their wave form. Amplifiers are used extensively in electrical communication and also for rendering perceptible sounds and other vibrational waves that could not otherwise be observed.

In telephony the carbon transmitter amplifies the effect of the sound waves at the same time that it converts them into electrical waves. Thermionic amplifiers are inserted at intervals in long telephone lines and are also used to actuate loud-speaking receivers. In radio telephony and telegraphy, as well as in carrier current systems, in which the high-frequency currents are transmitted over wires, amplifiers are used in both the high and low-frequency paths. Amplifiers also find application in the reception of submarine cable signals and in submarine and subterranean signalling. Outside the communication field they make possible refined electric and other measurements; they have been used to assist the deaf to hear, to render heart sounds audible, to detect and locate aeroplanes and submarines, and for a variety of other purposes.

The essential features of an amplifier are a source of energy such as a battery, and a means whereby the flow of energy from this source may be controlled by the wave to be amplified in such a way that the variations of the original wave are reproduced upon an enlarged scale in the wave set up by this flow. Almost all of the amplifiers in use up to 1910 were of the type of the telephone transmitter, which depends upon variations in the electrical resistance of a mass of granular carbon which result from variations in mechanical pressure. When it was desired to amplify electrical variations as at an intermediate point in a long telephone line, a so-called "mechanical repeater" was used. Here the incoming current actuated a telephone receiver, the diaphragm of which agitated the carbon of a transmitter connected with the outgoing line. Various other devices based on changes in resistance with mechanical motion were developed to meet particular needs, notably those of submarine cable telegraphy.

With the beginning of the period under review the amplifying possibilities of electric discharge devices were coming to be recognized. After a period of experimentation in which a variety of forms were developed, those involving arcs and gaseous discharges gave way to the three-electrode high vacuum thermionic (*see* THERMIONICS) type variously known as audion, valve, triode, vacuum tube and pliotron. In the thermionic amplifier the current from the battery traverses a path between two electrodes in a highly evacuated glass bulb. The current between these electrodes consists of a stream of electrons emitted by the hot cathode or "filament" which is heated by current from an auxiliary source. The magnitude of this electron current is controlled by the potential of a third electrode or "grid" situated between the filament and plate and having openings through which the electrons pass. The source of the wave to be amplified is con-

nected with the grid and filament so that the potential of the grid relative to the filament varies in accordance with the wave to be amplified. Similar variations are thus impressed on the current from the battery. Any external circuit included in the path of this current then receives an amplified copy of the impressed wave. To secure maximum amplification the amplifier proper is generally connected with the external circuits through special connecting circuits. Transformers are used for this purpose at voice frequencies and tuned circuits at radio frequencies.

(R. V. L. H.)

AMPLITUDE, the extreme range of a fluctuating quantity. In mathematics and physics the word is generally used in connection with periodic functions or motions and denotes the maximum difference or displacement from the mean value (sometimes called the semi-amplitude since the whole range is double). In navigation the amplitude of a heavenly body is the angular distance of the point at which it rises or sets from the east or west point.

AMPSANCTUS or **AMSANCTUS** (mod. *Sorgente Mefita*), a small lake in the territory of the Hirpini, rom. S.E. of Aeclanum, close to the Via Appia. There are now two small pools which exhale carbonic acid gas and sulphuretted hydrogen. A temple of the goddess Mephitis had a cave with suffocating vapours and the place was brought into connection with legends of the infernal regions.

AMPTHILL, ODO WILLIAM LEOPOLD RUSSELL, 1ST BARON (1829–1884), British diplomatist and ambassador, was born in Florence on Feb. 20, 1829, the son of Maj.-Gen. Lord George William Russell. His education, like that of his two brothers—Hastings, who became eventually 9th duke of Bedford, and Arthur, who sat for a generation in the House of Commons as member for Tavistock—was carried on entirely at home, under the general direction of his mother, whose beauty was celebrated by Byron in *Beppo*. Lady William Russell was as strong-willed as she was beautiful, and certainly deserved to be described as she was by Disraeli, who said in conversation: "I think she is the most fortunate woman in England, for she has the three nicest sons." In March 1849 Odo was appointed by Lord Malmesbury attaché at Vienna. He was employed successively in the foreign office in London, in Paris, Constantinople and Florence. In 1858 he was sent to reside in Rome, where he remained for 12 years, till Aug. 1870. During all that period he was the real though unofficial representative of England at the Vatican, and his consummate tact enabled him to do more than an ordinary man could have done in a stronger position. Although he sympathized with those who laboured to prevent the extreme partisans of papal infallibility from having everything their own way, yet he made it clear to his own government that all efforts were useless, and seems to have had no illusions as to the result of the debate. In 1868 Odo Russell married Lady Emily Theresa Villiers, the daughter of Lord Clarendon. In 1870 he was appointed assistant under-secretary at the foreign office, and in Nov. of that year was sent on a special mission to the headquarters of the German army, where he remained till 1871.

In 1870 Russia had taken advantage of the collapse of France and of her own cordial relations with Prussia to denounce the Black Sea clauses of the Treaty of Paris of 1856. Russell, in an interview with Bismarck, pointed out that unless Russia withdrew from an attitude which involved the destruction of a treaty solemnly guaranteed by the powers, Great Britain would be forced

to go to war "with or without allies." This strong attitude was effective, and the question was ultimately settled by the conference which met in London in 1871. Though the result was to score a distinct diplomatic success for the Liberal government, the bellicose method employed threatened to create trouble for the ministry in parliament. On Feb. 16, 1871, accordingly, Gladstone, in answer to a question, made an enigmatical statement on the subject which was interpreted as an attack on Russell. A little later in the same year, however, he was made ambassador at Berlin.

Russell remained at Berlin, with only brief intervals of absence, from Oct. 16, 1871, till his death at Potsdam on Aug. 25, 1884. He was third plenipotentiary at the Berlin congress. He was raised to the peerage in 1881. At the conference about the Greek frontier, which followed the congress of Berlin, he was the only British representative. During all this long sojourn in the Prussian capital he did everything that he could to bring about close and friendly relations between Great Britain and Germany.

He was succeeded as 2nd baron by his son, ARTHUR OLIVER VILLIERS RUSSELL (b. 1869), who was private secretary to Mr. Chamberlain, 1895-97, and governor of Madras, 1899-1906. In 1904 he acted temporarily as Viceroy of India. He served in France throughout the World War. The legitimacy of his grandson was impugned by the complex proceedings popularly known as the "Russell baby case," which, commenced in 1921, was ended in the infant's favour in 1924.

AMPTHILL, urban district, Bedfordshire, England, 44m. N.N.W. of London by the L.M.S.R. Pop. (1931) 2,167. It lies on the southern slope of a low range of hills, in a well-wooded district. The church of St. Andrew contains a monument to Richard Nicolls (1624-72), who received the submission of New Amsterdam (later New York) in 1664, and became its first English governor. Ampthill Park became in 1818 the seat of Lord Holland. In the park a cross marks the site of Ampthill Castle, the residence of Catherine of Aragon while her divorce from Henry VIII. was pending. Lace-making is said to have been introduced by Catherine of Aragon, but is now practically extinct. Straw-plaiting for hat-making survives to some extent, but the interests of the town are in the main purely agricultural.

AMPULLA, a small, narrow-necked, round-bodied vase for holding liquids, especially oil and perfumes. It was used in ancient times for toilet purposes and anointing corpses, being then buried with them. Gildas mentions *ampullae* as used by the Britons in his time, and St. Columba is said to have used an ampulla in crowning King Aidan. In the Western Church the name is still applied to the vessel containing the oil consecrated by the bishop for ritual uses. It occurs in the English coronation service in connection with the ancient ceremony of anointing by the archbishop of Canterbury, which is still observed. The ampulla of the regalia of England takes the form of an eagle. The ampulla known as *la sainte ampoule*, at Reims, from which the kings of France were anointed (supposed to have been brought from heaven by a dove for the coronation of Clovis), was destroyed at the Revolution. The word is used in biology for a certain portion of the anatomy of a plant or animal.

AMPUTATION means the removal of a part of the body. In a more restricted sense the term is applied to the removal of a

part or the whole of a limb in continuity. The conditions under which amputation becomes necessary are: (1) injury, (2) gangrene, (3) infection, (4) malignant tumour, (5) deformity, (6) pain. Experience in the World War taught surgeons that amputation is necessary much less often than was formerly supposed. Advances in reconstructive surgery have made it possible to rehabilitate badly damaged limbs without amputation, and modern methods of preventing and controlling infection have lessened the danger from this source. However, some injuries still demand amputation under certain conditions, notably avulsion of part of a limb, compound fractures, crushing and lacerating wounds and irreparable injury of the main artery of a limb. In the case of a definite gangrene it is usually a choice between a slowly advancing process, with the probability of an infection sooner or later, and amputation. In severe infections of a limb, especially if complicated by lesions of bone or joints, amputation may be a life-saving measure. Malignant tumours often necessitate amputation; deformities and pain occasionally do so.

AMRAM (died 875), a famous *gaon* or head of the Jewish Academy of Sura (Persia) in the 9th century. He was author of many "Responsa," but his chief work was liturgical. He was the first to arrange a complete liturgy for the synagogue, and his Prayer Book (*Siddur Rab 'Amram*) was the foundation of most of the extant rites in use among the Jews. The *Siddur* was published in Warsaw in two parts (1865).

AMRAOTI, a town and district of India in Berar, Central Provinces. The district was reconstituted in 1905, when that of Ellichpur was incorporated with it. The town (pop., 40,694 in 1921) is the richest town of Berar, with the most numerous and substantial commercial population. It possesses a branch of the Bank of Bombay, with a famous cotton mart, as well as a large grain market, cotton presses, ginning factories and oil mills.

The district of Amraoti has an area of 4,704sq.m. In 1921 the population was 828,384. The district is an extensive plain, about 800ft. above sea-level, the general flatness being broken only by a small chain of hills, running in a north-westerly direction between Amraoti and Chandor, with an average height from 400 to 500ft. above the lowlands. The principal towns, besides Amraoti, are Karinja, Kolapur and Badnera.

'AMR-IBN-EL-ASS, or 'Amr (strictly 'AMR I. 'As), the Arab conqueror of Egypt, belonged to the tribe of Koreish (Qureish). He had in his youth opposed Mohammed, but he returned to his allegiance and joined the fugitive prophet at Mecca. 'Amr was one of the three generals sent by Abu Bekr to invade Syria in 633, but the main direction of the Syrian campaigns lay with Khālid-b. al-Walīd, who was sent to Syria when the imperial army advanced. In 639 Omar sent him as head of an expedition to Egypt. With an army of only about 4,000 men he took Pelusium (Jan. 640), and, with the aid of a new army of 10,000 men sent by Omar, defeated the imperial troops at Heliopolis (July 640). He then reduced Babylon (near Cairo) and founded the city of Fostat there. By a treaty made with the patriarch Cyrus, Alexandria was surrendered (Sept. 17, 642). 'Amr became the first Mohammedan governor of Egypt, but Omar, who perhaps feared the strong personal influence exercised by 'Amr, sent 'Abdallāh ibn Sa'd ibn 'Abi Sarh to supersede him in Upper Egypt. Othman, Omar's successor, extended 'Abdallāh's rule to Lower Egypt. But in 645 'Amr had to be recalled to quell a revolt in Alexandria. He retook the city (646) and once more withdrew. The statement that he burnt the great Alexandrian library has no basis except in the allegations of Abulfaraj (Bar-Hebraeus), who lived six centuries later. After the reconquest of Alexandria 'Amr extended Mohammedan rule to Barca and even to Tripoli.

It was probably the desire to secure the governorship of Egypt for himself that ranged 'Amr on the side of Mu 'āwīya in his war against Ali after the death of Othman. After the battle of Siffin (July 26-7, 657), when the dispute between Ali and Mu 'āwīya was put to arbitration, 'Amr represented Mu 'āwīya in the court held at Adhruh in 658 (see CALIPHATE and ALI). In 658 he reconquered Egypt in Mu 'āwīya's interest, and governed it till his death on Jan. 6, 664. In a pathetic speech to his children on

FROM "LE SACRE DE LOUIS XV.," PARIS, 1722
"LA SAINTE AMPOULE." PROBABLY THE MOST CELEBRATED AMPULLA. For centuries this ampulla held holy oil for anointing French kings. According to legend it was brought from heaven by a dove for the coronation of Clovis. In the illustration it is shown suspended from the neck in a jewelled, gold case

his death-bed, he bitterly lamented his youthful offence in opposing the prophet, although Mohammed had forgiven him and frequently affirmed that "there was no Mussulman more sincere and steadfast in the faith than 'Amr."

Sir W. Muir, *The Caliphate* (1891); E. Gibbon's *Decline and Fall*; M. J. de Goeje, *Mémoire sur la conquête de la Syrie* (Leiden, 1900); Alfred J. Butler, *Arab Conquest of Egypt* (1902); art. *EGYPT, History*, Mohammedan period.

'**AMR IBN KULTHŪM**, Arabian poet, author of one of the *Mo'allakāt*. Little or nothing is known of his life save that he was a member of the tribe of Taghlib and that he is said to have died of excessive wine-drinking. Some stories of him are told in the *Book of Songs* by Bar-Hebraeus (*q.v.*), vol. ix. pp. 181-5.

AMRITSAR, a city and district of British India. The city, the wealthiest in the Punjab, had in 1921 a population of 160,218, mostly Muslim and Hindu. About 200 looms are engaged in the carpet-making industry; an entrepôt trade in piece goods and a large business in skins and hides are carried on. It is a trade centre for the trans-Himalayan routes. The two yearly fairs are the most widely attended in the province. The town attained a certain notoriety in 1919 when riots occurred as a result of general unrest. On April 13 it was held necessary to disperse an unlawful gathering in the Jallianwala Bagh, and as a result nearly 400 Indians were killed by gunfire, and a considerable number wounded. Amritsar city is chiefly notable as the centre of the Sikh religion and the site of the Golden Temple, the chief worshipping place of the Sikhs. Ram Das, the fourth *guru*, laid the foundations of the city upon a site granted by the emperor Akbar. He also excavated the holy tank from which the town derives its name of Amrita Saras, or Pool of Immortality. It is upon a small island in the middle of this tank that the Golden Temple is now situated. After many vicissitudes the city and surrounding district fell under the sway of Ranjit Singh at Lahore, and passed with the rest of the Punjab into the possession of the British after the second Sikh war. The Golden Temple is thus called on account of its copper dome, covered with gold foil. A Sikh college for university education was opened in the neighbourhood in 1897. Amritsar district is a nearly level plain, with a very slight slope from east to west. Numerous branches of the Upper Bari Doab canal intersect the district, affording ample means of irrigation. The North Western railway and Grand Trunk road, which runs parallel with it, afford the principal means of communication and traffic. The area of the district is 1,593sq.m.; pop. (1921) 929,374. It is the headquarters of the Sikh religion, containing 287,004 Sikhs as against 204,435 Hindus and 423,724 Mohammedans. The principal crops are wheat, pulse, maize, millet, with some cotton and sugar-cane. There are factories for ginning and pressing cotton.

AMROHA, a town of British India, in the Moradabad district of the United Provinces; noteworthy for the tomb of Sheikh Saddu, a Mohammedan Saint. Pop. c. 42,000.

AMRUM or **AMROM**, a German island in the North sea, off the coast of Schleswig-Holstein, south of Sylt. Pop. (1925) 858. It is 6m. long and 3m. broad, with an area of 10½sq.m., and is reached from the mainland by a regular steamboat service to Wittdün; or at low water from Föhr. Amrum consists of a treeless sandy expanse, but a fringe of rich marshes affords good pasture-land. The principal place is Nebel, connected by a light railway with Wittdün. (See also *FRISIAN ISLANDS*.)

AMRU'-UL-QAIS or **IMRU'-UL QAIS**, **IBN HUJR**, Arabian poet of the 6th century, the author of one of the *Mo'allakāt* (*q.v.*), was regarded by Mohammed and others as the most distinguished poet of pre-Islamic times. He was of the kingly family of Kinda, and his mother was of the tribe of Taghlib. While he was still young, his father was killed by the Bani Asad, and his life was devoted to the attempt to avenge his father's death. He wandered from tribe to tribe to gain assistance, but his attempts were always foiled by the persistent following of the messengers of Mundhir of Hira (Hira). By means of Hārith of Ghassān he procured an introduction to the Byzantine Emperor Justinian. After a long stay in Constantinople he was named phylarch of Palestine, and received a body of troops from Justin II. With

these he started on his way to Arabia. It is said that he was charged before the emperor with the seduction of a princess, and that Justin sent him a poisoned cloak, which caused his death at Ancyra.

BIBLIOGRAPHY.—His poems are contained in W. Ahlwardt's *The Divans of the six ancient Arabic Poets* (London, 1870), and have been published separately in M.G. de Slane's *Le Diwan d'Amro'lkaïs* (Paris, 1837); a German version with life and notes in F. Rückert's *Amrilaïs der Dichter und König* (Stuttgart, 1843). Many stories of his life are told in the *Kitāb ul-Aghānī*, vol. viii., p. 62-77.

AMSDORF, NICOLAUS VON (1483-1565), German Protestant reformer, was born on Dec. 3 1483, at Torgau, on the Elbe and died at Eisenach on May 14 1565. He was educated at Leipzig, and then at Wittenberg. Throughout his life he remained one of Luther's most determined and active supporters. He was with him at the Leipzig conference (1519), and the Diet of Worms (1521); and was in the secret of his Wartburg seclusion.

He assisted the first efforts of the Reformation at Magdeburg (1524), at Goslar (1531) and at Einbeck (1534); took an active part in the debates at Schmalkalden (1537), where he defended the use of the sacrament by the unbelieving; and (1539) spoke out strongly against the bigamy of the landgrave of Hesse. After the death of the count palatine bishop of Naumburg-Zeitz, he was installed there (Jan. 20 1542), though in opposition to the chapter, by the elector of Saxony and Luther. His position was a painful one, and he longed to get back to Magdeburg, but was persuaded by Luther to stay. After Luther's death (1546) he took part in founding Jena University (1548); opposed the "Augsburg Interim" (1548); and superintended the publication of the Jena edition of Luther's works. He urged the separation of the High Lutheran party from Melancthon (1557), got the Saxon dukes to oppose the Frankfort Recess (1558) and continued to fight for the purity of Lutheran doctrine. Many letters and other short productions of his pen are extant in manuscript, especially five thick volumes of *Amsdorfiana*, in the Weimar library. They are a valuable source for our knowledge of Luther. A small sect, which adopted his opinion on good works, which he held to be useless, was called after him.

Kirche*, vol. iii., ed. M. Meurer (1863); art. by G. Kawerau in Herzog-Hauck, *Realencyk. für prot. Theologie* (3rd ed., Leipzig, 1896).

AMSLER, SAMUEL (1791-1849), Swiss engraver, was born at Schinznach, in the Canton of Aargau. He studied his art under Johan Heinrich Lips (1758-1817) and Karl Ernst Hess, at Munich, and from 1816 pursued it in Italy, and chiefly at Rome, till in 1829 he succeeded his former master Hess as professor of copper engraving in the Munich academy. He was a passionate admirer of Raphael and had great success in reproducing his works. Amslers' principal engravings are: "The Triumphal March of Alexander the Great" and a full-length "Christ," after the sculptures of Thorwaldsen and Dannecker; the "Entombment of Christ" and two "Madonnas" after Raphael; and the "Union between Religion and the Arts," after Overbeck, his last work, on which he spent six years.

AMSTERDAM, the chief city of Holland, in the province of North Holland, on the south side of the Y or IJ, an arm of the Zuider Zee, in 52° 22' N. and 4° 53' East. Pop. (1925) 718,046. It has communications by railway and canal in every direction; steam-tramways connect it with Edam, Purmerend, Alkmaar and Hilversum, and electric railways with Haarlem and the seaside resort of Zandvoort. Amsterdam, the "dam or dyke of the Amstel," is so called from the Amstel, the canalized river which passes through the city to the Y. Its beginnings centre around a small sea-fishing settlement. In the 13th century it was held in fee by the lords of Amstel of the bishops of Utrecht and in 1204 Giesebrecht II. built a castle here. A little later Giesebrecht III. constructed a dam to keep out the sea, and around the castle and dam the city grew. The first mention of the town is in 1275, in a charter of Floris IV., count of Holland, exempting it from certain taxes.

In 1296 the place passed out of the hands of the lords of Amstel, owing to the part taken by Giesebrecht IV. in the murder

of Count Floris V. Count John (d. 1304), with the approval of the bishop of Utrecht, bestowed the fief on his brother, Guy of Hainaut. Guy gave the town its first charter in 1300, with a bailiff (*schout*) and judicial assessors (*scabini* or *schoppen*), the overlord's supremacy being guarded, and an appeal lying from the *scabini*, in cases of disagreement, to Utrecht. In 1342 more extensive privileges were granted by Count William IV., including freedom from tolls by land and water in return for certain annual dues. In 1482 the town was surrounded with walls. During the religious troubles of the 16th century its prosperity increased owing to influx of refugees from Antwerp and Brabant. Amsterdam, influenced by its trading interests, did not join the other towns in revolt against Spain until 1578. In 1587 the earl of Leicester made an unsuccessful attempt to seize it. The great development of Amsterdam was due, however, to the treaty of Westphalia in 1648, by which its rival, Antwerp, was ruined, owing to the closing of the Scheldt. The city held out obstinately against the stadtholders, and in 1650 opened the dykes to prevent William II. seizing it. The same device was successful against Louis XIV. in 1672; and Amsterdam, now reconciled with the stadtholder, was one of the staunchest supporters of William III. against France. In 1787 Amsterdam was occupied by the Prussians, and in 1795 by the French under Pichegru. It was then made capital of the Batavian Republic and afterwards of the kingdom of Holland. In 1810 this was united with the French empire and Amsterdam was recognized officially as its third town, following Paris and Rome. The modern city has been built to a great extent over boggy ground and the foundations of the buildings were made secure by driving long piles into the firm clayey soil below. On the landward side the city is surrounded by a fosse or canal, and was at one time fortified; but the ramparts have been demolished and replaced by gardens and houses; one gateway, the Muiderpoort, still stands. Within the city are four canals (*grachten*) with their ends resting on the Y, extending in polygonal crescents nearly parallel to each other and to the outer canal. Each of these canals marks the line of the city walls and moat in some phase of growth. Lesser canals intersect the others radially, thus virtually dividing the city into a number of islands. The nucleus of the town lies within the innermost crescent canal, and, with the large square, the Dam, in the centre, represents the area of Amsterdam about the middle of the 14th century. At one end of the enclosing canal is the Schreijerstoren (1482) or "Weepers' Tower," on the ancient harbour, the scene of former sorrowful leave-takings. Between this and the next crescent (Heeren Gracht) there sprang up, on the east, the foreign quarter where the large Jewish population is located, and where Rembrandt lived (1640-1656) and Spinoza was born (1632). Beyond the Heeren Gracht lie the Keizer Gracht and the Prinsen Gracht respectively, and these three celebrated canals, with their tree-bordered quays and old-fashioned houses, form the principal thoroughfares of the city. West of the Prinsen Gracht lies the district called De Jordaan, a corruption of Le Jardin, for its streets are named after various flowers. It was formed by the settlement of French refugees after the revocation of the Edict of Nantes. The outermost crescent canal is called the Singel Gracht (girdle canal), and marks the boundary of the city at the end of the 17th century. The streets in old Amsterdam are narrow and irregular. The city's long connection with the sea produced its seamen, merchants and explorers. With the accumulation of mercantile wealth, coupled with a tradition of keenness of mind and action (enhanced by the arrival of refugees), the city became the home of artists, philosophers and religious leaders. Around the Dam are the Nieuwe Kerk and the palace. The palace, in classical style, was originally built as a town-hall in 1648-1655 by Van Kempen. Since 1768 it has been used as a royal residence. The exterior is beautifully decorated. The great hall is lined with white Italian marble, and in spite of its enormous dimensions the roof is unsupported by pillars. The Nieuwe Kerk (St. Catherine's) is a fine Gothic building dating from 1408. Internally it is remarkable for its remains of ancient stained glass, fine carvings and interesting monuments, including one to the famous Admiral de Ruyter (d. 1676). The new exchange (1901) lies between the Dam and the central station

(1889). The Oude Kerk (St. Nicholas), so called (c. 1300), contains some beautiful stained glass of the 16th and 17th centuries, by Pieter Aertsen of Amsterdam (1508-1575) and others. One window contains the arms of the burgomasters of Amsterdam from 1578 to 1767. The North church was the last work of the architect Hendrik de Keyser (1565-1621) of Utrecht. The Roman Catholic church of St. Nicholas (1886) replaced a com-

VIEW ALONG THE CANAL IN AMSTERDAM. IN THE BACKGROUND, THE ROMAN CATHOLIC CHURCH OF ST. NICHOLAS, BUILT IN 1886

mon dwelling-house, now the Museum Amstelkring of ecclesiastical antiquities. Among the Jewish synagogues, the largest is that of the Portuguese Jews (1670). The St. Antonieswaag, built as a town gate (1488-1585), contains the city archives; and the Trippenhuis, the Royal Society of Science, Letters and Fine Arts. The Ryks, or State museum, is a finely situated building in the Dutch Renaissance style, erected in 1876-1885. It has a department of general antiquities and a large gallery of pictures of the Dutch and Flemish schools. Famous pictures in the Ryks museum are those from the Trippenhuis, the so-called "Night-watch" and the "Syndics of the Cloth Hall" by Rembrandt, and the "Banquet of the Civic Guard," by van der Helst. The Trippenhuis gallery consisted of the pictures brought from The Hague by Louis Bonaparte, king of Holland, and belonging to the collection of the Orange family dispersed during the Napoleonic period. The municipal museum contains a collection of furniture, paintings, etc. The Joseph Fodor museum (1860) contains modern French and Dutch pictures. The pictures collected by Burgomaster Jan. Six (d. 1702) are (with the exception of the family Rembrandts) in the Ryks museum. The Willet Holthuysen museum (1895) has exhibits of furniture and porcelain.

Modern Amsterdam extends southward beyond the Singel Gracht. In the middle of this new region lies the Vondel park, named after the great national poet Joost van den Vondel (d. 1679), whose statue stands therein. The Willems park adjoining was added later. In the older part of the town the chief open space is the Zoological gardens in the north-east corner, set out by the *Natura Artis Magistra* Society in 1838, which are well known. There is attached a library and an ethnological and natural history museum. Nearby are the Botanical gardens. The public squares include the Sophiaplein, with the picturesque mint-tower; the Rembrandtplein, with a monument to the painter; the Thorbeckeplein, with monument, and the Leidscheplein, with the large theatre, rebuilt in 1890-94 after a fire. There are two universities, the Free university (1880), and the more ancient State university of Amsterdam, founded in 1632, but reconstructed in 1887. In addition to the numerous science laboratories the State university possesses a very fine library of about 100,000 volumes, including the Rosenthal collection of over 8,000 books on Jewish literature. The Society for Public Welfare (1785) promotes the education and improvement of all classes, and has branches all over Holland. Among other societies are the *Felix Meritis* (1776) and the *Arti et Amicitiae* (1839), whose art exhibitions are of a high order.

Harbour and Commerce.—The first attempt to overcome the evils wrought to trade by the slow formation of the Pampus sandbank, at the entrance to the Y from the Zuider Zee, was the construction of the North Holland canal to the Helder in 1825. The route was long and difficult, and in 1876 a larger and more direct canal was built across the isthmus to the North Sea at Ymuiden. The serious rivalry of Rotterdam, especially with regard to the transit trade, and the inadequacy of the Keulse Vaart, which connected the city with the Rhine, led to the construction in 1892 of the Merwede canal to Gorinchem. Meanwhile a complete transformation took place on the Y to suit the new requirements of the city's trade. The three islands built out into the river serve to carry the railway across the front of the city, and form a long series of quays. On either side are the large East and West docks (1825-1834), and beyond these stretch the quays at which the ocean liners are berthed. On the west of the West dock is the timber dock, and east of the East dock is another series of islands joined together so as to form basins and quays, one of which is the State Marine dock (1790-1795), with the arsenal and admiralty offices. Opening out of one of the crescent canals which penetrate the city from the Y is the State Entrepôt dock (1900), the free harbour of Amsterdam, where the produce from the Dutch East Indies is stored. The trade with the East Indies increased enormously within the period 1910-25. On the north side of the Y are the dry docks and the petroleum dock. The principal imports are timber, coal, grain, ore, petroleum, tobacco, tea, coffee, cocoa, sugar, Peruvian bark and other drugs. Diamond-cutting has long been practised by the Jews and forms one of the most characteristic industries of the city. Other industries include sugar-refineries, soap, oil, glass, iron, dye and chemical works; distilleries, breweries, tanneries; tobacco and snuff factories; shipbuilding and the manufacture of machinery and stearine candles. The Amsterdam exchange is still of considerable importance. The celebrated Bank of Amsterdam (1609) was dissolved in 1796 and the present Bank of the Netherlands was established in 1814. The city suffered considerably during the World War from the loss of a great part of the former extensive financial business. The position continued bad until shipping on the Rhine increased after the German mark had been stabilized and conditions in the Ruhr had improved.

The total goods traffic of the port increased 50% between 1913 and 1924. The Coen harbour, on the south side of the Y, with 3,112 ft. of quays for seagoing ships and 2,000 ft. for river craft, was opened in 1924, and plans were prepared for a new lock 1,292 ft. long at the entrance to the North Sea canal at Ymuiden. The canal itself was dredged to a depth of 33 ft. There is aeroplane service to London, Hamburg, Brussels and Paris.

See P. Scheltens, *Inventaris van het Amsterdamsche archief*, 3 vols. (1866-74). H. Brugmans and A. Loosjes, *Amsterdam in beeld* (1925).

AMSTERDAM, the only city of Montgomery county, N.Y., U.S.A., on the north bank of the Mohawk river, about 33 m. N.W. of Albany. It is on the main line of the New York Central railroad, the State barge canal and the direct highway between New York and Buffalo; and is served also by the Fonda, Johnstown and Gloversville railroad, and (through south Amsterdam) by the West Shore railroad. Hills on both sides of the river command fine views of the Mohawk valley. The city has an area of 6.05 square miles. The population was 33,524 in 1920, of whom 9,807 were foreign-born whites (including Poles, Italians, Lithuanians and Germans); and 34,817 in 1930.

Amsterdam manufactures rugs, brooms, carpets, pearl buttons, silk gloves, silk and cotton hosiery, underwear (silk, rayon, cotton and woollen), sweaters, aprons, box board, box machinery, paper boxes, looms, boilers, linseed oil, oil cakes, "mendets," paper clips and novelties. The total output of the city's 56 factories in 1927 was valued at \$45,809,707. The city has a large jobbing trade and is the retail trading centre for a territory covering more than 1,000 square miles. Outbound freight amounts to over 300,000 tons annually, and it is estimated that more than twice as much comes in. There is a breeding farm for race-horses on the outskirts of the city. The assessed valuation of property was \$30,927,988 in 1927. A memorial has been erected to the 2,500

men from Amsterdam who served in the World War; and a system of memorial playgrounds and parks was completed in 1927. Three miles away, on a trolley line, is Fort Johnson, built by Sir William Johnson, the well-known American pioneer (see *JOHNSON, SIR WILLIAM*). Amsterdam was settled about 1775, and was called Veedersburg until 1804, when its present name was adopted. It was incorporated as a village in 1830 and chartered as a city in 1885.

AMSTERDAM ISLAND, an uninhabited island in the Indian ocean, in 37° 47' S. and 77° 34' E., about 40 m. N. of St. Paul island and approximately midway between the Cape of Good Hope and Tasmania. It is a nearly extinct volcano rising 2,989 ft. from the sea. Exposed to the westerly winds and enshrouded in mists, the island possesses a vegetation of mosses and lichens and is the haunt of innumerable sea birds. Fishing (cod and seal) is profitably carried on by fishermen from Réunion. It was discovered by Anthony van Diemen in 1633 and annexed by France in 1893. In 1871, the British frigate "Megaera" was wrecked there and most of the 400 persons on board had to remain more than three months on the island. The *Mémoires* of a Frenchman, Captain François Péron (Paris, 1824), who was marooned three years on the island (1792-95), are of much interest.

See Schenck, *Vergleichende Darstellung der Pflanzengeographie der Subantarktischen Inseln*, 2 vols. (Jena, 1905).

AMUCK, RUNNING (or more properly *Amok*), the native term for the homicidal mania which attacks Malays. A Malay will suddenly and apparently without reason rush into the street armed with a kris or other weapon, and slash and cut at everybody he meets till he is killed. These frenzies were formerly regarded as due to sudden insanity. It is now, however, certain that the typical *amok* is the result of circumstances, such as domestic jealousy or gambling losses, which render a Malay desperate and weary of his life. It is, in fact, the Malay equivalent of suicide. "The act of running *amuck* is probably due to causes over which the culprit has some amount of control, as the custom has now died out in the British possessions in the peninsula, the offenders probably objecting to being caught and tried in cold blood" (W. W. Skeat). The word is widely used in a figurative sense.

Though so intimately associated with the Malay there is some ground for believing the word to have an Indian origin, and the act is certainly far from unknown in Indian history. Some notable cases have occurred among the Rajputs. Thus, in 1634, the eldest son of the raja of Jodhpur ran amuck at the court of Shah Jahan, failing in his attack on the emperor, but killing five of his officials. During the 18th century, again, at Hyderabad (Sind) two envoys, sent by the Jodhpur chief in regard to a quarrel between the two States, stabbed the prince and 26 of his suite before they themselves fell.

In Malabar there were certain professional assassins known to old travellers as *Amouchi* or *Amuco*. The nearest modern equivalent to these words would seem to be the Malayalam *amarkhan*, "a warrior" (from *amar*, "fight"). The Malayalam term *chaver* applied to these ruffians meant literally those "who devote themselves to death." In Malabar was a custom by which the zamorin or king of Calicut had to cut his throat in public when he had reigned 12 years. In the 17th century a variation in his fate was made. He had to take his seat, after a great feast lasting 12 days, at a national assembly, surrounded by his armed suite, and it was lawful for anyone to attack him, and if he succeeded in killing him the murderer himself became zamorin. (See Alex. Hamilton, "A New Account of the East Indies," in Pinkerton's *Voyages and Travels*, viii. 374.) In 1600 30 would-be assassins were killed in their attempts.

These men are called *amar-khan*, and it has been suggested that their action was "running amuck" in the true Malay sense. Another proposed derivation for *amouchi* is Sanskrit *amokshya*, "that cannot be loosed," suggesting that the murderer was bound by a vow, an explanation more than once advanced for the Malay *amuck*; and *amokshya* in such a sense is unknown in Malayalam.

AMUL or **AMOL**, a town of Persia, in the province of Mazandaran, 23m. S.W. of Balfrush. Pop. about 10,000. It is situated on both banks of the Heraz river, and is an important "fall-line" town between the Elburz mountains of the south and the low shore-land of the Caspian sea. Around the present site are ruins that tell of Amul's former greatness. They include the mausoleum of King Seyed Kavvam Ud-Din (d. 1379) and a mosque dating from 793.

AMULET, a charm, generally, but not invariably, hung from the neck, to protect the wearer against witchcraft, sickness, acci-

BY COURTESY OF THE BRITISH MUSEUM

FRONT AND BACK VIEW OF THE 15TH-CENTURY GLENLYON BROOCH Of Scottish workmanship, this amulet formerly belonged to the Campbells of Glenlyon. It is about 5½ in. in diameter, of heavy silver-gilt, set in front with pearls which stand about an inch above the flat surface, alternating with crystals and amethysts. The back is inscribed with the names Caspar, Melchior and Balthazar, followed by "Consumatum" ("It is finished") the last words of Christ on the cross

dents, etc. (Late Lat. *amuletum*, origin unknown). Amulets have been of many different kinds, and formed of different substances—stones, metals and strips of parchment being the most common, with or without characters or legends engraved or written on them. Gems have often been employed and greatly prized, serving for ornaments as well as for charms. Certain herbs, too, and animal preparations have been used in the same way. In setting them apart to their use as amulets, great precautions have been taken that fitting times be selected, stellar and other magic influences propitious, and everything avoided that might be supposed to destroy or weaken the force of the charm. The belief in the prevalence of occult evil influences engenders trust in amulets and similar preservatives against them. There are references to, and apparently correctives of, these customs in the Mosaic injunctions to bind portions of the law upon the hand and as frontlets between the eyes, as well as write them upon the door-posts and the gates.

Amulets were much used by the ancient Egyptians, among the Greeks and Romans, and in the early Christian Church; hence the emphatic protests of Chrysostom, Augustine and others against them. *Talisman*, from the Arabic, is a word of similar use; but while talismans bring good luck or transmit qualities, amulets are preventive. A talisman, whose "virtues are still applied to for stopping blood and in cases of canine madness," gives name to one of Sir Walter Scott's novels.

AMUN: see **AMMON**.

AMUNDSEN, ROALD (1872–1928), Norwegian explorer, was born July 16 1872, in Borge, a country district near Sarpsborg in south-eastern Norway. Educated at Christiania (now Oslo) he took his B.A. degree in 1890 and began to study medicine, but gave it up and went to sea in 1894. During the following nine years, Amundsen, with the tenacity of purpose which was one of his chief characteristics, prepared himself for his

future career as an explorer, and in 1903–06 he led an expedition consisting of himself and six companions through the North-west Passage, on board the "Gjøa," a little sloop of 47 tons, and succeeded in fixing the position of the magnetic North Pole.

His next expedition, on board the "Fram," originally intended as a North Polar expedition, by a dramatic surprise, became a South Polar expedition (1910–12), and was the first actually to reach the South Pole. After his return in 1913 he resumed his preparations for a North Polar expedition but was stopped by the outbreak of the World War. He remained inactive until 1918 when he left Norway on board the "Maud," a new vessel, with the aim of drifting from the North Siberian Islands across the Pole. Baffled in this undertaking owing to the fact that the Polar stream did not prove to be constant, he decided to force the Polar basin in an aeroplane.

On his fourth attempt he succeeded, using the semi-rigid dirigible "Norge," built in Italy. Starting with the American Ellsworth, from Spitsbergen, May 11 1926, he flew to the Pole, which he circled twice, thence across the unexplored Arctic basin to Point Barrow, Alaska, and finally landed, May 14, at Teller on Bering Sea. The total distance traversed was 2,700 m., the time occupied in the flight being only 71 hours (see **POLAR EXPLORATION**). When General Nobile's airship, "Italia," returning from the North Pole was wrecked on May 24, 1928, Amundsen chivalrously volunteered to go in search of him. He left Bergen for Spitsbergen in an aeroplane on June 17, and was not heard of again. See R. Amundsen, *My Life as an Explorer* (1927); B. Partridge, *Amundsen* (1929).

AMUR, the chief river of Eastern Asia north of the Hwang-ho and about 3,000 miles in length. It traverses from west to east a series of tilted earth-blocks which present a steep face to the south-east and a gentle back-slope to the north-west. The course of the river is, therefore, alternately towards the north-east, when it flows parallel to the north-east to south-west trending ridges and towards the south-east, when it cuts across them. It is formed by the confluence of the Shilka, rising in Transbaikalia, and the Argun, rising on the back-slope of the Great Khingan, one of these earth-blocks. It receives its most important tributaries, the Sungari and the Ussuri, from the similar back-slope of the earth-block overlooking the Sea of Japan. Both tributaries enter from the south. Since the late 17th century, when the Chinese came into contact with the extending power of Russia, the Amur has had considerable political significance. The Argun head-stream was taken as part of the boundary between the two empires at the Treaty of Nerchinsk (1689), and the present boundary between Manchuria and Siberia follows the line of the Argun, Amur and Ussuri, thus forming one of the longest river frontiers in the world. The river is highest in summer, the season of rains, and then the Sungari, draining North Manchuria, has a greater volume of water than the Amur itself. In winter the river is frozen over and navigation is confined to the six months from May to October. For boats drawing four feet of water, the Amur is then navigable for over 2,000 miles up to Stretensk and the Sungari up to Kirin. But the fact that its outlet lies so far to the north deprives the Amur of much of its value and, moreover, it has as a competitor the Chinese Eastern railway which is linked with more southerly ports at Vladivostok and in South Manchuria.

BY COURTESY OF THE BRITISH MUSEUM

RINGS WITH MAGICAL INSCRIPTIONS

The larger is of silver engraved with astrological characters. The smaller, of gold, has the form of a serpent with its tail in its mouth. It is inscribed ASLSV—Salus

AN AZTEC PENDANT

Made of jasper and supposed to have magical powers in stanching blood

A JADEITE CELT (ELIZABETHAN) AMULET

Mounted in silver, the shank is inscribed, "The right Elatrope, the special stone to staunche bleeding and good against poyson."

AMUR PROVINCE, a part of the Far Eastern Area of the Russian S.F.S.R. Area 236,785sq.km. Pop. (1926) 394,000 (urban 75,588). Its boundaries are, on the south, the Amur river, on the west and north-west Zei Province, on the east and north-east Nikolaievsk Province and Khabarovsk Province. It includes the broad fertile plain which stretches from the junction of the rivers Zeya and Amur at Blagovyeschensk to the Bureya or Little Khingan mountains 250m. below. The river here is broad and slow-flowing; at Blagovyeschensk, 1,200m. from its mouth, its elevation is less than 400ft. The climate is milder than that of the Lena basin though it has severe winters, the principal drawback being that the maximum rainfall is in July and August, too late to be of the best service to crops, though oats, wheat, buckwheat, barley and potatoes are successfully grown. The average temperature at Blagovyeschensk is 17°F. in January and 70° F. in July. Above Blagovyeschensk the river valley is narrow and there is little land available for cultivation. The mountain slopes are thickly forested and yield furs and timber, while the valley of the Zeya is noted for its gold mines. There are also deposits of iron-ore, coal, antimony and fluorspar. Horses, cattle, pigs, sheep and camels are reared. The Amur, Zeya and Bureya rivers furnish boat communication in summer and sledge in winter, but the province has developed markedly since the construction of the trans-Siberian railway through it, with its branch to Blagovyeschensk, which is an important trading and culture centre. The region was known to the Russians in the 17th century, and began to be settled by them in 1847. In 1858 China ceded to Russia the whole left bank of the Amur, and the right below the Ussuri confluence, and in 1860 the whole territory between the Ussuri and the Eastern sea.

AMURATH: see MURAD.

AMYGDALIN (Gr. *ἀμυγδαλή*, almond), a glucoside $C_{20}H_{27}NO_{11}$, was isolated from bitter almonds by H. E. Robiquet and A. F. Boutron-Charlard in 1830, and subsequently investigated by Liebig and Wöhler, and others. It is extracted from almond cake by boiling alcohol; on evaporation of the solution and the addition of ether, amygdalin is precipitated as white minute crystals. It has been found to be a glucoside (*q.v.*) of formula $C_{20}H_{27}NO_{11}$, being a compound of *d*-glucose, benzaldehyde and hydrocyanic (prussic acid), into which it is decomposed by sulphuric acid. Hydrochloric acid gives mandelic acid, *d*-glucose and ammonia. The enzyme maltase partially decomposes it, giving *d*-glucose and mandelic nitrile glucoside, $C_6H_5CH(CN)O \cdot C_6H_{11}O_5$. Emulsin, on the other hand, decomposes it into benzaldehyde, prussic acid and two molecules of glucose; this enzyme occurs in the bitter almond, and consequently the seeds invariably contain free prussic acid and benzaldehyde. (See GLUCOSIDES, NATURAL.)

AMYGDALOID, a term meaning "almond-shaped," used in anatomy and geology.

AMYL ACETATE, a colourless, neutral, mobile liquid resembling jargonelle pears in odour. Hence its use as an essence in the manufacture of "peardrops." Owing to its solvent action in cellulose, cellulose esters (*q.v.*) etc., it is also used in photography, in the celluloid and varnish industries, in the preparation of "dope" for aeroplane construction, etc. Its chemical formula is $CH_3CO_2C_5H_{11}$. (See also ACETIC ACID.)

AMYL ALCOHOLS. There are eight of these alcohols theoretically possible. All are known, and the most important is *isobutyl* carbinol (or *isoamyl* alcohol), the chief constituent of fermentation amyl alcohol, and consequently present in fusel oil (*q.v.*). It can be extracted from fusel oil by shaking this with strong brine, discarding the brine layer and collecting the portion boiling between 125° and 140°C. By shaking this product with hot milk of lime, separating the oily layer, drying it with calcium chloride and collecting the fraction boiling between 128° and 132°C, a further degree of purification may be effected.

Isoamyl alcohol is a colourless liquid of specific gravity 0.8248 (0°C), boiling at 131.6°C, slightly soluble in water, easily soluble in alcohol, ether, chloroform, and benzene. It possesses a characteristic strong smell and a sharp burning taste. It is oxidized by chromic acid mixture to *isovalerylaldehyde*.

The eight amyl alcohols all have the general formula $C_5H_{11}OH$, the differences being due to the different ways in which the carbon atoms are linked together and to the hydrogen and oxygen atoms. In normal amyl alcohol, we have a "straight chain" primary alcohol, $CH_3 \cdot CH_2 \cdot CH_2 \cdot CH_2 \cdot CH_2OH$, which can be regarded as derived from the hydrocarbon *n*-pentane (normal pentane) by replacement of one end hydrogen atom with the alcoholic (hydroxyl) group. Methyl-*n*-propyl carbinol,

and di-ethyl carbinol, $C_2H_5 \cdot CHOH \cdot C_2H_5$, are two secondary amyl alcohols, also derivable from *n*-pentane. From the hydrocarbon $(CH_3)_2CH \cdot CH_2 \cdot CH_3$ can be derived *isobutyl* carbinol or *isoamyl* alcohol, $(CH_3)_2CH \cdot CH_2 \cdot CH_2OH$, methyl *isopropyl* carbinol, $(CH_3)_2CH \cdot \dot{C}HOH \cdot CH_3$, dimethyl ethyl carbinol,

and active amyl alcohol $CH_3 \cdot \dot{C}(CH_2OH)H \cdot CH_2 \cdot CH_3$. And from the hydrocarbon $(CH_3)_4C$ can be derived tertiary butyl carbinol, $(CH_3)_3C \cdot CH_2OH$. Three of these contain "asymmetric carbonations" (marked *) and can therefore exist each in two optically active forms and one optically inactive form (see STEREO-CHEMISTRY); the amyl alcohols include four primary alcohols (containing the group $\cdot CH_2OH$), three secondary alcohols (containing the group $\cdot CHOH$) and one tertiary alcohol (containing the group $\cdot COH$).

All the amyl alcohols can be obtained synthetically, *isoamyl* alcohol by the action of trioxy-methylene $(CH_2O)_3$, on *isobutyl* magnesium bromide, an example of Grignard's reaction. The synthesis of tertiary butyl carbinol proved the most difficult and was finally achieved in 1891 by L. Tisserand who reduced a mixture of trimethylacetic acid and trimethylacetyl chloride with sodium amalgam. It is a solid which melts at 48°–50°C and boils at 112–113°C.

AMYL NITRITE (*isoamyl* nitrite), a liquid which finds application in medicine, since it reduces blood pressure and retards the pulse. It is prepared by passing nitrous fumes (from starch and concentrated nitric acid) into warm *isoamyl* alcohol; or by distilling a mixture of 26 parts of potassium nitrite in 15 parts of water with 30 parts of *isoamyl* alcohol in 30 parts of sulphuric acid. It is a yellow-coloured liquid of specific gravity 0.877, boiling at about 95°–96° C, of characteristic penetrating odour, and having the composition $C_5H_{11}ONO$. It is insoluble in water, but dissolves readily in alcohol, ether, glacial acetic acid, chloroform or benzene. It is easily decomposed by nascent hydrogen, with the formation of ammonia and *isoamyl* alcohol; and on hydrolysis with caustic potash it forms potassium nitrite and *isoamyl* alcohol. When the liquid is dropped on to fused caustic potash, it forms potassium valerate.

AMYMONE, in ancient Greek legend, daughter of Danaüs. With her sisters, she had been sent to look for water, the district of Argos being then parched through the anger of Poseidon. Amymone having thrown her spear at a stag, missed it, but hit a satyr asleep in the brake. The satyr pursued her, and she called for help on Poseidon, who appeared and for love of her beauty caused a spring to well up, which received her name. Aeschylus wrote a satyric drama on the subject. By the god Amymone became the mother of Nauplius, the wrecker. Her meeting with Poseidon at the spring is frequently represented on ancient coins and gems.

See Apollodorus ii., 1, 4; Hyginus, *Fab.* 169; Propertius ii., 26.

AMYNTAS I., king of Macedonia (c. 540–498 B.C.), was a tributary vassal of Darius Hystaspes and the first Macedonian ruler to have relations with other countries. He made an alliance with the Peisistratidae, and when Hippias was driven out of Athens he offered him the territory of Anthemus on the Thermaic gulf, hoping to turn the Greek party feuds to his own advantage (Herodotus v. 17, 94; Justin vii. 2; Thucydides ii. 100; Pausanias ix. 40). (See MACEDONIAN EMPIRE.)

AMYNTAS II. or III., King of Macedonia from 393 (or 389) to 369 B.C. He came to the throne after the ten years of confusion which followed the death of Archelaus, and showed the same taste for Greek culture and its representatives. In 383 B.C.

he was driven out by the Illyrians, but in the following year, with the aid of the Thessalians, he recovered his kingdom. He concluded a treaty with the Spartans, who helped him to reduce Olynthus (379 B.C.). He also entered into a league with Jason of Pherae, and cultivated the friendship of Athens. The youngest of his three sons was the famous Philip of Macedon.

See Diodorus xiv. 89, xv. 19, 60; Xenophon, *Hellenica*, v. 2; Justin vii. 4.

AMYOT, JACQUES (1513–1593), French writer, was born of poor parents, at Melun, on Oct. 30, 1513. He was educated at the University of Paris and then at Bourges, where he was made professor of Greek and Latin through the influence of Margaret of Valois. Here he translated *Théagène et Chariclée* from Heliodorus (1547 fol.), for which he was rewarded by Francis I. with the abbey of Belloczane. He was thus enabled to go to Italy to study the Vatican text of Plutarch, on the translation of whose *Lives* (1559; 1565) he had been some time engaged. On the way he turned aside on a mission to the Council of Trent. Returning home, he was appointed tutor to the sons of Henry II., by one of whom (Charles IX.) he was afterwards made grand almoner (1561) and by the other (Henry III.) was appointed, in spite of his plebeian origin, commander of the order of the Holy Ghost. Pius I. promoted him to the bishopric of Auxerre, and here he continued to live in comparative quiet, repairing his cathedral and perfecting his translations, for the rest of his days, though troubled towards the close by the insubordination and revolts of his clergy. He died on Feb. 6, 1593, bequeathing, it is said, 1,200 crowns to the hospital at Orleans for the twelve "deniers" he received there when "poor and naked" on his way to Paris. He translated seven books of Diodorus (1554), the *Daphnis et Chloe* of Longus (1559) and the *Opera Moralia* of Plutarch (1572). His lively and idiomatic version of Plutarch, *Vies des hommes illustres*, was translated into English by Sir Thomas North, and supplied Shakespeare with materials for his Roman plays. The translation of Plutarch was his magnum opus. His other translations were subsidiary. The version of Diodorus he did not publish, although the manuscript had been discovered by himself. Amyot took great pains to find and interpret correctly the best authorities, but the interest of his books lies in the simplicity and purity of language which won the praise of Montaigne. His translation reads like an original work. The personal method of Plutarch appealed to a generation addicted to memoirs. Amyot's book, therefore, obtained an immense popularity and exercised great influence over successive generations of French writers.

There is a good edition of the works of Amyot from the firm of Didot (25 vols., 1818–21). See also Auguste de Blignières, *Essai sur Amyot et les traducteurs français au xvi^e siècle* (1851).

AMYRAUT, MOÏSE (1596–1664), also known as *Amyraldus*, French Protestant theologian and metaphysician, studied at Orleans, Poitiers, and then at Saumur under the famous Scottish Protestant teacher, John Cameron. He was made pastor of Saumur and professor of theology there. Amyraut and his colleagues, Louis Cappel and Josué de la Place, also Cameron's pupils, collaborated in the *Theses Salmurienses*, and in 1631 published his *Traité des religions*.

Amyraut was chosen by the national synod of 1631 to present to the king the complaint of the French Protestants against the revocation of the Edict of Nantes. His oration on this occasion is famous in the history of French Protestantism. Later he conferred with Richelieu, but without success, on the possibilities of reconciliation.

Amyraut held fast to Calvinism, but in his *Traité de la prédestination* he tried to mitigate its harsher features by his "universalism hypotheticus"—that God predestines all men to happiness on condition of their having faith. For this doctrine he was thrice accused of heresy before the synod, but without success. His most important metaphysical work was *De l'élévation de la foy et de l'abaissement de la raison en la créance des mystères de la religion* (1641). But perhaps he is better remembered by his simpler works of devotion, which have remained fireside favourites of the French Protestant peasantry. Moïse Amyraut died Jan. 18, 1664.

ANA, a town on the Euphrates in 34°30' N. and 42° E., 192m. below Deir, and 119 above Hit. The town has retained its name at least since the beginning of the 2nd millennium B.C., but the actual site seems to have changed slightly. The earlier writers describe it as being on an island, and even as late as the 16th

BY COURTESY OF THE MUSEUM OF THE UNIVERSITY OF PENNSYLVANIA

ANA ON THE EUPHRATES, FORMERLY A FLOURISHING TRADE STATION CONTROLLING THE WATER-WAY

century A.D. at least a part of the town was so situated. At this time, however, the greater part of the town already lay on the right bank of the Euphrates, to which it is confined to-day. The town is important as the end of the desert journey from Tadmor in the west, as a station controlling the Euphrates waterway, and as a point of contact and trade with the desert to the south-west. In the early 17th century A.D. at one of its most flourishing periods, the emir of Ana seems to have controlled the desert as far west as Tadmor; it was then the most flourishing Arab town on the Euphrates but since then it has fallen into decay, suffering inroads from the desert. It was formerly known for its wine, and, later on, for its palm groves; it is a region of great fertility.

To-day the population is 15,000 (a rather uncertain estimate) most of whom are Sunni Arabs. It is a centre of considerable trade along the valley road, and for trade with the Bedouins. It is also an agricultural oasis, growing mainly cereals, fruit and dates, the latter of which are traded, and its exports also include butter and wool. The modern motor route and aeroplane track to Damascus runs south of the old caravan route and leaves the Euphrates at Ramadi.

ANA, a Latin neuter plural termination appropriated to various collections of the observations and criticisms of eminent men, delivered in conversation and recorded by their friends, or discovered among their papers after their decease. Though the term Ana is of comparatively modern origin, the introduction of this species of composition is not of recent date. It appears, from d'Herbelot's *Bibliothèque Orientale*, that from the earliest periods the Eastern nations were in the habit of preserving the maxims of their sages. From them the practice passed to the Greeks and Romans. Plato and Xenophon treasured up and recorded the sayings of their master Socrates; and Arrian, in the concluding books of his *Enchiridion*, now lost, collected the casual observations of Epictetus. The numerous apophthegms scattered in Plutarch, Diogenes Laertius, and other writers, show that it was customary in Greece to preserve the colloquially expressed ideas of illustrious men. It appears that Julius Caesar compiled a book of apophthegms, in which he related the *bons mots* of Cicero.

But though vestiges of Ana may be traced in the classical ages, it is only in modern times that they have come to be regarded as constituting a distinct species of composition, comprising literary anecdotes, critical reflections, and historical incidents, mingled with the detail of *bons mots* and ludicrous tales. The term Ana seems to have been applied to such collections as far back as the beginning of the 15th century. Francesco Barbaro, in a letter to Poggio, says that the information and anecdotes which Poggio and Bartolommeo of Montepulciano had picked up during a literary excursion through Germany will be called *Ana*.

Poggio Bracciolini (q.v.) is the first eminent person of modern times whose jests and opinions have been transmitted to pos-

terity. During the pontificate of Martin V., Poggio and other members of the Roman chancery were in the habit of assembling in a common hall adjoining the Vatican, in order to converse freely on all subjects. The jests and stories which occurred in these unrestrained conversations were collected by Poggio and formed the chief materials of his *Facetiae*. This collection, which forms a principal part of the *Poggiana* printed at Amsterdam in 1720, is chiefly valuable as recording interesting anecdotes of eminent men of the 14th and 15th centuries. It also contains a number of quibbles or *jeux de mots*, and a still greater number of *facetiae*, idle and licentious stories.

Though Poggio was the first person whose remarks and *bons mots* were collected under the name of Ana, the *Scaligerana*, which contains the opinions of Joseph Scaliger, was the first work published under that appellation. There are two collections of Scaligerana—the *Prima* and *Secunda*. The first was compiled by a physician named François Vertunien, sieur de Lavau, who attended a family with whom Joseph Scaliger resided. It was published in 1669, under the title of *Prima Scaligerana, nusquam antehac edita*. The second work, known as *Secunda Scaligerana*, was collected by two brothers of the name of Vassan, students of the University of Leyden, of which Scaliger was one of the professors. Being particularly recommended to Scaliger, they were received in his house and enjoyed his conversation.

In imitation of the *Scaligerana*, a prodigious number of similar works appeared in France towards the end of the 17th and beginning of the 18th century. At first these collections were confined to what had fallen from eminent men in conversation; but they were afterwards made to embrace fragments found among their papers, and even passages extracted from their works and correspondence. Of those which merely record the conversations of eminent men, the best known and most valuable is the *Ménagiana*. Gilles Ménage was a person of good sense, of various and extensive information and of a most communicative disposition. A collection of his oral opinions was published in 1693, soon after his death.

The *Perroniana*, which exhibits the opinions of Cardinal du Perron, was compiled from his conversation by C. Dupuy, and published by Vossius in 1666. The *Thuana*, or observations of the president de Thou, have usually been published along with the *Perroniana*, but first appeared in 1669.

The *Valesiana* is a collection of the literary opinions of the historiographer Adrien de Valois, published by his son.

The *Fureteriana* (1696) contains the *bons mots* of Antoine Furetière, the Academician, the stories which he was in the habit of telling, and a number of anecdotes and remarks found in his papers after his decease.

The *Chevræana* (1697), so called from Urbain Chevreau, is more scholarly than most works of a similar description and probably more accurate, as it differs from the Ana proper, of which the works described above are instances, in having been published during the life of the author and revised by himself.

Parrhasiana (1699–1701) is the work of Jean le Clerc, a professor of Amsterdam, who bestowed this appellation on his miscellaneous productions with the view of discussing various topics of philosophy and politics with more freedom than he could have employed under his own name.

The *Huetiana* contains the detached thoughts and criticisms of P. D. Huet (1630–1722), bishop of Avranches, which he himself committed to writing when he was far advanced in life.

The *Casauboniana* presents us with the miscellaneous observations, chiefly philological, of the celebrated Isaac Casaubon.

Besides the above a great many works under the title of Ana appeared in France about the same period. Thus, the opinions and conversations of Charpentier, Colomesius and St. Evremont were recorded in the *Carpenteriana*, *Colomesiana* and *St. Evremontiana*; and those of Segrais in the *Segraisiana*—a collection formed by a person stationed behind the tapestry in a house where Segrais was accustomed to visit, of which Voltaire declared, “que de tous les Ana c’est celui qui mérite le plus d’être mis au rang des mensonges imprimés, et surtout des mensonges insipides.” The Ana, indeed, from the popularity which they now

enjoyed, were compiled in such numbers and with so little care that they became almost proverbial for inaccuracy.

Of the examples England has produced of this species of composition, perhaps the most interesting is the *Walpoliana*, a transcript of the literary conversation of Horace Walpole, earl of Orford. Most other works which in England have been published under the name of Ana, as *Baconiana*, *Atterburyana*, etc., are rather extracts from the writings and correspondence of eminent men than memorials of their conversation.

Of the productions which belong to the class, though they do not bear the name of Ana, the most celebrated are the *Colloquia Mensalia* of Luther and Selden’s *Table-Talk*. The former, which comprehends the conversation of Luther with his friends and coadjutors in the great work of the Reformation, was first published in 1566. The *Table-Talk* of Selden contains a more genuine and undisguised expression of the sentiments of that eminent man than we find in his more studied productions. It was published after his death by Richard Milward, his amanuensis, who affirms that for 20 years he enjoyed the opportunity of daily hearing his discourse, and made it his practice faithfully to commit to writing “the excellent things that usually fell from him.”

The most remarkable collection of Ana in the English language—and, indeed, in any language—is to be found in a work which does not correspond to the normal type either in the name or in form. In his *Life of Samuel Johnson, LL.D.*, Boswell relates that to his remark, *à propos* of French literature, “Their Ana are good,” Johnson replied, “A few of them are good; but we have one book of that kind better than any of them—Selden’s *Table-Talk*.” Boswell’s own work, however, is incomparably superior to all. Mrs. Thrale (who called her note-book “Thraliana”) gave the world a volume in the orthodox Ana style in her *Anecdotes of the late Samuel Johnson, LL.D.* A good modern collection of Ana is Mountstuart Grant Duff’s *Notes from a Diary* (1897–1905).

J. C. Wolf has given a history of the Ana in a preliminary discourse to his edition of the *Casauboniana*, published in 1710. In the *Répertoire de bibliographies spéciales, curieuses, et instructives*, by Peignot, there is a *Notice bibliographique* of these collections; but many of the books there enumerated consist of mere extracts from the writings of popular authors.

ANABAPTISTS, a name given by their enemies to various sects which denied the validity of infant baptism and for other reasons became prominent in Germany and elsewhere during the period of the Reformation. (Gr. ἀναβαπτίζω, rebaptize.) So used, the word is too well known to be discarded, though it describes these sects by one of the least important of their distinctive doctrines and practices. The Anabaptists of Germany are historically noteworthy, not because they insisted on rebaptism as a condition of admission to their community, but because the enthusiasm of the Reformation manifested itself in them in a form and manner altogether peculiar. Their views as to the true function of the church and its relation to the State, and the efforts which they made to realize these views, furnish a problem, partly theological, partly historical, of which a satisfactory solution is not easy. To one who looks merely at the extravagance and lawlessness which appear on the surface, fanaticism and madness, credulity and imposture may provide a sufficient explanation of the whole Anabaptist movement, but a deeper insight will find elements in it which are quite inconsistent with such a supposition.

Anabaptism, as a system, may be described as the Reformation doctrine carried to its extreme limit; the Anabaptists were the extreme left in the army of the Reformers. The hostility of the orthodox Reformers to them cannot conceal the fact that the most peculiar doctrines of the Anabaptists were to them only corollaries—illegitimately drawn, as the orthodox Reformers believed—from the fundamental principle common to both: the independence of the individual judgment, and the supreme importance of the subjective element, personal faith, in religion. The connection of this principle with their theory of the church and its relation to the State, their doctrine of the sacraments, and even their political risings, is evident.

The history of the Anabaptist movement in its outward development is brief but eventful. In 1521 their first rising took

place at Zwickau, under the leadership of Thomas Münzer, Lutheran pastor of that place. Compelled to leave Zwickau, Münzer visited Bohemia, resided two years at Allstedt in Thuringia, and in 1524 spent some time in Switzerland. During this period he proclaimed his revolutionary doctrines in religion and politics with growing vehemence, and, so far as the lower orders were concerned, with growing success. The crisis came in the so-called Peasants' War in south Germany in 1525. In its origin a revolt against feudal oppression, it became, under the leadership of Münzer, a war against all constituted authorities, and an attempt to establish by force his ideal Christian commonwealth, with absolute equality and the community of goods. The total defeat of the insurgents at Frankenhausen (May 15 1525), followed as it was by the execution of Münzer and several other leaders, proved only a temporary check to the Anabaptist movement. Here and there throughout Germany, Switzerland and the Netherlands there were zealous propagandists, through whose teaching many were prepared to follow as soon as another leader should arise. A second and more determined attempt to establish a theocracy was made at Münster, in Westphalia (1532-35). Here the sect had gained considerable influence, through the adhesion of Rothmann, the Lutheran pastor, and several prominent citizens; and the leaders, Johann Matthyszoon or Matthiesen, a baker of Haarlem, and Johann Bockholdt, a tailor of Leyden, had little difficulty in obtaining possession of the town and deposing the magistrates. Vigorous preparations were at once made, not only to hold what had been gained, but to proceed from Münster, as a centre to the conquest of the world. The town being besieged by Francis of Waldeck, its expelled bishop (April 1534), Matthiesen, who was first in command, made a sally with only 30 followers, under the fanatical idea that he was a second Gideon, and was cut off with his entire band. Bockholdt, better known in history as John of Leyden, was now supreme. Giving himself out as the successor of David, he claimed royal honours and absolute power in the new "Zion." He justified the most arbitrary and extravagant measures by the authority of visions from heaven, as others have done in similar circumstances. With this pretended sanction he legalized polygamy, and himself took four wives, one of whom he beheaded with his own hand in the market-place in a fit of frenzy. As a natural consequence of such licence, Münster was for 12 months a scene of unbridled profligacy. After an obstinate resistance the town was taken by the besiegers on June 24, 1535, and in January 1536, Bockholdt and some of his more prominent followers, after being cruelly tortured, were executed in the market-place. The outbreak at Münster was the crisis of the Anabaptist movement. It never again had the opportunity of assuming political importance, the civil powers naturally adopting the most stringent measures to suppress an agitation whose avowed object was to suppress them. It is difficult to trace the subsequent history of the sect as a religious body. The fact that after the Münster insurrection the very name Anabaptist was proscribed in Europe, is a source of twofold confusion. The enforced adoption of new names makes it easy to lose the historical identity of many who really belonged to the Münster Anabaptists; but, on the other hand, has led to the classification of many with the Münster sect who had no connection with it. The latter mistake, it is to be noted, has been much more common than the former. The Mennonites, for example, have been identified with the earlier Anabaptists on the ground that they included among their number many of the fanatics of Münster. But the continuity of a sect is to be traced in its principles, and not in its adherents, and it must be remembered that Menno and his followers expressly repudiated the distinctive doctrines of the Münster Anabaptists. They have never aimed at any social or political revolution, and have been as remarkable for sobriety of conduct as the Münster sect was for its fanaticism (see MENNONITES). In English history frequent reference is made to the Anabaptists during the 16th and 17th centuries, but there is no evidence that any considerable number of native Englishmen ever adopted the principles of the Münster sect. Many of the followers of Münzer and Bockholdt seem to have fled from persecution in

Germany and the Netherlands to be subjected to a persecution scarcely less severe in England. The excesses of John of Leyden, the Brigham Young of that age, cast an unjust stigma on the Baptists, of whom the vast majority were good, quiet people who merely carried out in practice the early Christian ideals of which their persecutors prated. Broadly speaking, the various branches of the Anabaptist movement held the following doctrines in common. (1) They taught that Jesus did not take the flesh from his mother, but either brought his body from heaven or had one made for him by the Word. The Anabaptists were accused of denying the incarnation of Christ: they did, but not in the sense that he was not divine; they rather denied him to be human. (2) They condemned oaths, and also the reference of disputes between believers to law-courts. (3) The believer must not bear arms or offer forcible resistance to wrongdoers, nor wield the sword. No Christian has the *ius gladii*. (4) Civil government belongs to the world, is Caesar. The believer who belongs to God's kingdom must not fill any office, nor hold any rank under government, which is to be passively obeyed. (5) Sinners or unfaithful ones are to be excommunicated and excluded from the sacraments and from intercourse with believers unless they repent, according to Matt. xviii. 15 *seq.*, but no force is to be used towards them. Some sects calling themselves *Spirituales*, *Pneumatici* or *Perfecti* also held that the baptized, or regenerate man, cannot sin, a very ancient tenet: though the outward man sinned, the inward man sinned not.

One of the most notable features of the early Anabaptists is that they regarded any true religious reform as involving social amelioration. The Socialism of the 16th century was necessarily Christian and Anabaptist. Lutheranism was more attractive to grand-ducal patriots and well-to-do burghers than to the poor and oppressed and disinherited. The Lutherans and Zwinglians never converted the Anabaptists. Those who yielded to stress of persecution fell back into Roman Catholicism and went to swell the tide of the Catholic reaction.

See Beard, *The Reformation in its relation to Modern Thought and Knowledge* (Hibbert lectures, 1883); Lindsay, *History of the Reformation* (1907), vol. ii.; Hastings, *Encyclopaedia of Religion and Ethics*, art. "Anabaptism" with references given there; and the general church histories of the period.

ANABASIS, the title given by Xenophon (*q.v.*) to his narrative of the expedition of Cyrus the younger against his brother, Artaxerxes of Persia, 401 B.C., and adopted by Arrian for his history of the expedition of Alexander the Great (Gr. *ἀνάβασις*, a march up country).

ANABOLISM, the biological term for the building up in an organism of more complex from simpler substances, constructive metabolism. (See BIOLOGY; PHYSIOLOGY.)

ANACHARSIS (*c.* 600 B.C.), a Scythian philosopher, the son of a chief of a nomadic tribe of the Euxine shores and a Greek woman. He went on an embassy to Athens about 589 B.C. and became acquainted with Solon, and it is said that he was initiated into the Eleusinian mysteries. After he had spent several years at Athens, he travelled through different countries and returned home filled with the desire of teaching his countrymen the laws and the religion of the Greeks. According to Herodotus he was killed by his brother. His simple and forcible language originated the proverbial expression "Scythian Eloquence," but his epigrams are as unauthentic as the letters which are often attributed to him.

See Herodotus iv. 76; Lucian, *Scytha*; Cicero, *Tusc. Disp.* v. 32; Diog. Laert. i. 101.

ANACHRONISM, a neglect or falsification, whether wilful or undesigned, of chronological relation (Gr. *ἀνά*, back, and *χρόνος*, time). Its commonest use is in the ante-dating of events, circumstances, or customs; *i.e.*, in the introduction, especially in works of imagination that rest on a historical basis, of details borrowed from a later age. Anachronisms may originate through ignorance of the progress of the arts and sciences and the other ascertained facts of history; artists on the stage and on canvas, in story and in song in all ages and all countries have been inclined to assimilate their *dramatis personae* to their own nationality and time.

ANACOLUTHON, a defectively constructed sentence which does not run on as a continuous whole. When a writer or speaker is full of his subject, or is carried rapidly along by the passion of the moment, such inconsequents are very apt to occur. Of Niebuhr it is told that his oral lectures consisted almost entirely of anacoluthic constructions. To this kind of licence some languages, as Greek and English, readily lend themselves; while the grammatical rigidity of others, as Latin and French, admits of it but sparingly. The following is an example:—"And he charged him to tell no man; *but go show thyself*," etc. (Luke v. 14). The anacoluthon, as might be expected, is found several times in the plays of Shakespeare, e.g.,

Keep your word, Phoebe, *that you'll marry me*,
Or else, refusing me, *to wed this shepherd*.

(*As You Like It*, Act v. 4.)

ANACONDA, a city of Montana, U.S.A., 26 m. N.W. of Butte, at an elevation of 5,300 ft.; the county seat of Deer Lodge county. The population in 1930 was 12,494. The Butte, Anaconda and Pacific (electric) railway connects the city with Butte and with the Northern Pacific, the Great Northern, the Oregon Short Line and the Chicago, Milwaukee, St. Paul and Pacific railways. Anaconda is a product of the Anaconda Mining Company, which in 1884 erected a plant on the north side of Warm Springs valley in order to treat locally the ore from its copper mines at Butte. This site was selected because there was no adequate water supply nearer. The first plant merely smelted the ore into matte which was sent to Swansea or to Baltimore for further reduction. In 1892 a full installation of converters was provided, and since then only metallic copper has been shipped from the district. In 1902 a new plant was erected one mile east of the city, increasing the capacity of the works to 17,000 tons of ore daily. The normal output of copper is 16% of the total produced in the United States, 9% of the world's production. Production of zinc and of manganese has been increasingly important since 1910 and 1918 respectively. The works employ 2,700 men, and use 20,000 electric horse-power from the water-power plants of the Montana Power Company, and 10,000 more that is developed in steam engines on the spot. It is the largest non-ferrous reduction plant in the world.

ANACONDA (*Eunectes murinus*), an aquatic boa, inhabiting the swamps and rivers of Brazil, northeastern Peru and the Guianas in South America. It is the largest of American snakes and rivals the reticulated python as the largest snake in the world. Exaggerated tales have been told by travellers of its size and swallowing capacity, but the largest known have rarely exceeded 30 ft. in length. There is very great dread of this snake among the natives, though authenticated cases of it having attacked man are few. The general colour of the anaconda is olive-brown, with large oval black spots arranged in two alternating rows along the back, and with smaller white-eyed spots along the sides. The belly is whitish, spotted with black. The head is elongate, flat, and very distinct from the neck. The top of the head is very dark and is separated from the paler sides by a black streak forming a point on the snout. An oblique streak is found on each side between the eyes. The nostrils are situated between three large shields. The anaconda feeds chiefly at night upon birds and other animals which it kills by constriction. In contrast to the boa, which rarely takes to the water, the anaconda spends most of its time there, lying entirely submerged, with only a small part of its head above the surface, waiting for any suitable prey. Only seldom does it establish itself in the branches of trees like the boa. It is ovoviviparous and the young are about 36 in. long when born.

A smaller species of anaconda, *Eunectes notreus* inhabits Paraguay and the northern part of Argentina.

ANACONDA COPPER MINING COMPANY, an American company, incorporated in 1895 to succeed the Anaconda Mining Company; it has, through the acquisition of various mining and fabricating companies in the United States and elsewhere, developed into the world's premier company in the non-ferrous metal industry. Directly, or through its subsidiary and associated companies, it controls the annual production of more than 1,000,000,000 lbs. of copper, 500,000,000 lbs. of zinc, 150,000,000 lbs.

of lead, and more than 5% of the world production of silver. In addition to almost the entire ownership of the Butte (Montana) mining district, "the richest hill on earth," it has large investments in fifteen other American states, as well as in Canada, Mexico, Chile and Poland. It is also a large producer of lumber, coal, gold, arsenic, sulphuric acid, superphosphate, zinc oxide and white lead, and has a large custom smelting and refining business, with plants situated at Anaconda and Great Falls, Montana; Tooele, Utah; Miami, Arizona; East Chicago, Indiana; and Perth Amboy, New Jersey. Through its copper wire and rod mill situated at Great Falls, Montana, and through the ownership of The American Brass Company, it is the world's largest user of copper and manufacturer of copper and brass products. Among its subsidiary and associated companies are: American Brass Company and subsidiaries; Anaconda Lead Products Company; Andes Copper Mining Company; Arizona Oil Company; Butte, Anaconda & Pacific Railway Company; Butte Water Company; Chile Copper Company and subsidiary companies; Diamond Coal and Coke Company; Greene Cananea Copper Company; Inspiration Consolidated Copper Company; International Smelting Company; International Lead Refining Company; North Lily Mining Company; Raritan Copper Works; Santiago Mining Company; Tooele Valley Railway Company; Utah-Delaware Mining Company; Walker Mining Company, and the Silesian Holding Company, which, through the Silesian-American Corporation, controls the Giesche Spolka Akcyjna, a Polish corporation, one of the largest producers of zinc and coal in Europe. In 1926 the outstanding capital stock was \$150,000,000, and the total assets, \$514,507,008. The net income was \$14,231,219 and the surplus for the year, \$5,226,203.

The principal office of the Company is at Anaconda, Montana, the executive offices being in New York City. (E. O. S.)

ANACORTES, a city and a port of entry in Skagit county, Wash., U.S.A., occupying the upper end of Fidalgo island, about 20m. S. by W. of Bellingham in a direct line. It is connected with the mainland by the Great Northern railway and the San Juan extension of the Pacific highway; with Vancouver island by an automobile ferry, which winds through enchanting scenery; with the ports on Puget sound by regular steamboat service, and with all parts of the San Juan archipelago by smaller steamers. The population in 1930 was 6,564.

Anacortes has important fishing industries, and is a distributing point for the logs of fir, cedar, hemlock and spruce, brought down from British Columbia; and for the berries, the ginseng, golden-seal, and other medicinal plants, the cabbage seed, and other agricultural products of the region. It had the first glass factory of the North-west. There are large exporting lumber-mills and box-factories. Box shooks are shipped to all parts of the world. Deception Pass State park is four miles away, on the south-western end of Fidalgo island. The city was incorporated in 1889.

ANACREON, Greek lyric poet, was born about 560 B.C., at Teos, an Ionian city on the coast of Asia Minor. Little is known of his life, except a few scattered notices, not in all cases certainly authentic. He may have shared the voluntary exile of the mass of his fellow-townsmen, who, when Cyrus the Great was besieging the Greek cities of Asia (545), sailed to Abdera in Thrace, where they founded a colony. Anacreon seems to have taken part in the fighting, in which, on his own admission, he did not distinguish himself, but, like Alcaeus and Horace, threw away his shield and fled. He is said to have acted as tutor to Polycrates of Samos; that he enjoyed the tyrant's confidence we learn on the authority of Herodotus (iii. 121), who represents the poet as sitting in the royal chamber when audience was given to the Persian herald. Anacreon wrote many complimentary odes upon his patron. Like his fellow-lyrist, Horace, who was one of his great admirers, and in many respects of a kindred spirit, Anacreon seems to have been made for the society of courts. On the death of Polycrates, Hipparchus, who was then in power at Athens and inherited the literary tastes of his father Peisistratus, sent a special embassy to fetch the popular poet to Athens in a galley of 50 oars. Here he became acquainted with the poet Simonides, and other members of the brilliant circle which had gathered round Hipparchus. When this

circle was broken up by the assassination of Hipparchus, Anacreon seems to have returned to his native town of Teos, where, according to a metrical epitaph ascribed to his friend Simonides, he died and was buried. According to others, before returning to Teos, he accompanied Simonides to the court of Echebrates, a Thessalian dynast of the house of the Aleuadae. Lucian (*Macrob.* 26) mentions Anacreon as having completed 85 years. If an anecdote given by Pliny (*Nat. Hist.* vii. 7) is to be trusted, he was choked at last by a grape-stone, but the story has an air of mythical adaptation to the poet's habits. Anacreon was for a long time popular at Athens, where his statue was to be seen on the Acropolis, together with that of his friend Xanthippus, the father of Pericles. On several coins of Teos he is represented, holding a lyre in his hand. A marble statue found in 1835 in the Sabine district, and now in the Villa Borghese, is said to represent Anacreon.

AFTER A CAST IN THE METROPOLITAN MUSEUM OF ART
ANACREON

Anacreon had a reputation as a composer of hymns, as well as of those bacchanalian and amatory lyrics which are commonly associated with his name. Two short hymns to Artemis and Dionysus, consisting of eight and 11 lines respectively, stand first amongst his few undisputed remains, as printed by recent editors; but pagan "hymns" and "Anacreontic" poetry are often not unlike. The tone of Anacreon's lyric effusions has probably led to an unjust estimate of the poet's character. The "triple worship" of the Muses, Wine, and Love, ascribed to him as his religion in an old Greek epigram (*Anthol.* iii. 25, 51), may have been as purely professional in the two last cases as in the first, and his private character on such points was probably neither much better nor worse than that of his contemporaries. Athenaeus remarks acutely that he seems at least to have been sober when he wrote; and he himself strongly repudiates, as Horace does, the brutal characteristics of intoxication as fit only for barbarians and Scythians (*Fr.* 64). Of the five books of lyrical pieces by Anacreon which Suidas and Athenaeus mention as extant in their time, we have now but the merest fragments, collected from the citations of later writers. Those graceful little poems (most of them first printed from the mss. by Henry Stephens in 1554), which long passed among the learned for the songs of Anacreon, and which are well known to many English readers in the translations of Cowley and Moore, are really of much later date, though possibly here and there genuine fragments of the poet are included. Modern critics, however, regard the entire collection as imitations belonging to different periods—the oldest probably to Alexandrian times, the most recent to the last days of paganism. They will always retain a certain popularity from their lightness and elegance, and some of them are fair copies of Anacreon's style. A strong argument against their genuineness lies in the fact that the peculiar forms of the Ionic Greek, in which Anacreon wrote, are not to be found in these reputed odes, while the fragments of his poems quoted by ancient writers are full of Ionicisms. Again, only one of the quotations from Anacreon in ancient writers is to be found in these poems, which further contain no references to contemporaries, whereas Strabo (xiv. p. 638) expressly states that Anacreon's poems included numerous allusions to Polycrates. The character of Love as a mischievous little boy is quite different from that given by Anacreon, who describes him as "striking with a mighty axe, like a smith."

The best edition of the genuine fragments of Anacreon, as well as of the *Anacreontea*, is by Bergk (*Poetae lyrici graeci*, 1882). He includes in an appendix a similar collection of imitations from the

Anecdota graeca of P. Matrangola (1850), which had their origin in the beginning of the middle ages and resemble the Christian anacreontics of Sophronius.

ANACREONTICS (from the name of the Greek poet Anacreon), the title given to short lyrical pieces, of an easy kind, dealing with love and wine. The English word appears to have been first used in 1656 by Abraham Cowley, who called a section of his poems "anacreontiques," because they were paraphrased out of the so-called writings of Anacreon into a familiar measure which was supposed to represent the metre of the Greek. Half a century later, when the form had been much cultivated, John Phillips (1631–1706) laid down the arbitrary rule that an anacreontic line "consists of seven syllables, without being tied to any certain law of quantity." In the 18th century, the antiquary William Oldys (1696–1761) was the author of a little piece which is the perfect type of an anacreontic: this begins:

Busy, curious, thirsty fly,
Drink with me, and drink as I;
Freely welcome to my cup,
Could'st thou sip and sip it up.
Make the most of life you may;
Life is short and wears away.

In 1800 Tom Moore published a collection of erotic anacreontics which are also typical in form; Moore speaks of the necessity of catching "the careless facility with which Anacreon appears to have trifled," as a reason why anacreontics are often tame and worthless. He dwells, moreover, on the absurdity of writing "pious anacreontics," a feat, however, which was performed by several of the Greek Christian poets, and in particular by Gregory of Nazianzus and John of Damascus. (E. G.)

ANADYOMENE, a common Greek epithet of Aphrodite (Venus), expressive of her having sprung from the foam of the sea (from the Greek *anaduomenē*, "rising"). In a famous picture by Apelles she was represented as having just emerged from the sea and in the act of wringing her tresses. This painting was executed for the temple of Asclepius at Cos, from which it was taken to Rome by Augustus in part payment of tribute, and set up in the temple of Caesar. In the time of Nero, owing to its dilapidated condition, it was replaced by a copy made by the painter Dorotheus.

ANADYR, (1) a gulf, and (2) a river, in the extreme north-east of the Kamchatka province of the Far Eastern Area of the Russian S.F.S. Republics. The gulf extends from Cape Chukchi on the north to Cape Navarin on the south, forming part of the Bering sea. The river rises in the Stanovoi mountains as the Ivashki or Ivachno, about 67° N. and 173° E., flows through the Chukchi country, at first south-west and then east, and enters the Gulf of Anadyr after a course of about 500m. The country through which it passes is thinly populated, barren and desolate. For nine months of the year the ground is covered with snow. Reindeer, upon which the inhabitants subsist, are numerous.

ANAEMIA, a generic term for various forms of disease characterized by a defective constitution of the blood, or, more specifically, by a reduction in the oxygen-carrying power of the blood. This reduction is due, either to a decrease in the number of red blood corpuscles, or to a decrease in the amount of haemoglobin they contain, haemoglobin being that constituent of the red corpuscles which makes it possible for them to carry oxygen to the tissues and to play an important rôle in the transfer of carbon dioxide from the tissues to the lungs. The amount of haemoglobin that each red corpuscle contains is represented by a term known as the colour index, which is derived by dividing the percentage of haemoglobin by the percentage of red corpuscles.

Types of Anaemia.—The customary division is as follows: (a) the primary, those in which the cause is yet unknown; and (b) the secondary, those due to some known cause. Chlorosis and pernicious anaemia are primary anaemias. The anaemia caused by haemorrhage, malaria, chronic poisoning by known chemical and biological agents, parasites, malnutrition, malignant disease, etc., is secondary.

Symptoms.—Since the chief derangement in all anaemias is a reduction of the total amount of haemoglobin in the blood, the symptoms and pathological anatomy are quite similar in the dif-

ferent kinds of anaemia. Pallor of the skin and mucous membranes, shortness of the breath, palpitation, faintness, weakness, languor, headache, and usually gastro-intestinal disturbances, are the general symptoms. A special tendency to haemorrhage is frequently present. The physician frequently finds the heart to be dilated and hears systolic murmurs in the heart on auscultation. Anatomically the internal organs are pale, sometimes smaller than normal and atrophic, and their cells contain an excessive amount of fat. The spleen is enlarged in some anaemias and is usually denser than normal. The red bone-marrow, which forms the red corpuscles and haemoglobin, is increased in amount except in rare cases. The diagnosis depends on the clinical picture, the examination of the blood, and a number of other findings.

Causative Factors.—Obviously anaemia must be due to either one or a combination of the following factors: loss of blood, increased destruction of red corpuscles, or a disturbance of the red bone-marrow (erythroblastic tissue), leading to a decrease in the normal supply of red corpuscles or to a decrease in the amount of haemoglobin they contain. The red bone-marrow in health continually supplies the blood with red corpuscles which contain a constant amount of haemoglobin to take the place of those destroyed in the liver, spleen and other tissues; so that the number of red corpuscles and the total amount of haemoglobin in the blood remain constant.

If blood is lost, or if there is an increase in the destruction of red corpuscles, the red bone-marrow compensates by producing red corpuscles at a more rapid rate than normal. In such a case, especially if the loss, or destruction, is great, the red corpuscles so produced are frequently small, contain a subnormal amount of haemoglobin and may even contain a nucleus, which denotes that the cell is young. In the course of time these abnormal cells are replaced by normal cells and the red bone-marrow returns to a normal rate of production. But if the loss or destruction is continuous or intermittent, as in chronic anaemias, the blood contains more and more abnormal red corpuscles. The erythroblastic tissue further attempts to compensate for this continuous demand for red cells by invading and replacing the yellow marrow which does not form red corpuscles. If the demand is in excess of the capacity of the erythroblastic tissue to respond, the condition of the blood seen in the chronic anaemias develops, namely, a decrease in the number of red corpuscles, the presence of abnormal types of corpuscles, and a diminution of the total amount of haemoglobin in the blood.

In some of the anaemias it is possible to state definitely which of the above factors are concerned; in others opinion can be based only upon an interpretation of the known facts. In the anaemia that follows repeated haemorrhage, as occurs in ulcers of the gastro-intestinal tract, the obvious factor is the loss of blood. In the anaemias caused by haemolytic toxins, the destruction of red corpuscles is the chief factor concerned, although these toxins may also act on the erythroblasts or embryonic red corpuscles in the bone-marrow. In the anaemia secondary to malignant disease, *e.g.*, gastric cancer, the anaemia is due to a combination of several factors. First there is a toxæmic condition due to absorption of products of decomposition formed in the growth itself. But in addition there may be present loss of blood from haemorrhage; an increase in the destruction of red corpuscles in some cases; a disturbance of nutrition leading to a lack of proper food supply for the erythroblastic tissue; and the possible action of the autolytic products of the cancer cells which may inhibit the activity of the bone-marrow. The evidence of increased red corpuscle destruction can sometimes be obtained by examination of the spleen and liver, their cells containing a larger quantity of iron than normal, by examination of secretions or excretions, such as the bile and urine (haemoglobinuria), and by determining the fragility of the red corpuscles. The fragility of the red corpuscles is ascertained by determining their ability to withstand a hypotonic solution of sodium chloride without disintegrating, normal red corpuscles being able to resist a 0.4% solution, whereas "fragile corpuscles" will discharge their haemoglobin in a 0.5% solution. The evidence of disturbance of the red bone-marrow is obtained by detailed examination of the blood,

the cellular constituents being markedly altered. In the chronic anaemias regeneration and destruction, or loss, occur simultaneously, so that the blood picture gives an idea more of the capacity of the erythroblastic tissue to respond than of the amount of destruction that is occurring. In aplastic anaemia, a rare condition, the red bone-marrow, does not respond, and as a result the anaemia runs a rapid and progressive course without remissions, contrary to the usual course of the chronic anaemias.

Chlorosis.—Chlorosis and pernicious anaemia are primary anaemias that deserve special discussion because of their common occurrence. Chlorosis occurs almost exclusively in females between the ages of 14 and 25, the most frequent ages of onset being 14 and 15. This disease is characterized by a pronounced haemoglobin deficiency without a proportional decrease in red corpuscles. It is rarely directly fatal and is fortunately very amenable to treatment with iron preparations, blood transfusions being required only in advanced and stubborn cases. The administration by mouth of bone-marrow and spleen is also beneficial. Recurrences of the disease are quite common. The cause of chlorosis is unknown. All evidence shows that a haemolytic agent is probably not responsible. The erythroblastic tissue is at fault, particularly in the formation of haemoglobin. The fact that iron is so beneficial suggests that iron starvation is in some way related to the primary cause, which is also related in some way to the age of puberty and the function of menstruation. Because of this latter factor, some believe that the glands of internal secretion, especially the ovary, are at fault; but no conclusive evidence is as yet available. An improper diet, overwork, worry and lack of fresh air are predisposing factors. Chlorosis does not occur frequently in country-bred girls, which is probably due to the greater exposure to sunshine and "outdoor life," which these girls enjoy. In towns, too, it is less common than formerly. The symptoms of chlorosis are in general those of anaemia.

Pernicious Anaemia.—Pernicious anaemia is a disease of middle life and is twice as common in males as in females. It is characterized by a progressive anaemia interrupted by periods of temporary improvement, and by a fatal termination almost without exception in from two to five years, the body being rarely emaciated. The onset of this disease is slow and insidious. The skin is pale and later takes on a lemon tint. Languor, weakness and breathlessness are not marked at first, but later become extreme. The heart palpitates readily. The mucous membrane of the mouth is glossy and appears bloodless; the tongue is sore. The appetite fails and quite early in the disease acid disappears from the gastric secretion. Attacks of diarrhoea and abdominal pain frequently occur. There is a tendency to bleed into the skin and serous surfaces. Some patients experience sensations of numbness and tingling and complain of neurotic pains.

The blood picture is much changed, the red corpuscles being greatly reduced in number and very abnormal in shape and size, as well as in other respects. The red corpuscles contain an abundance of haemoglobin, the colour index being greater than 1.0. The white blood corpuscles are generally normal or diminished in number, but frequently abnormal forms are present. On post-mortem examination the bone-marrow is red and hyperplastic, except in cases of aplastic anaemia; lesions of the spinal cord are found; the gastric mucosa is frequently atrophic; the internal organs show fatty degeneration; the lymph glands may be deepened in colour (haemolymph glands), and there is much iron pigment in the kidneys, liver and spleen.

In contrast to chlorosis, there appears to be no serious difficulty in the formation of haemoglobin in pernicious anaemia. Many evidences of excessive blood destruction are present, particularly the increased iron content of the organs, free haemoglobin in the blood serum and urine, the frequent occurrence of jaundice, and the increased fragility of the red corpuscles. A condition simulating pernicious anaemia occurs in continued poisoning with toluylenediamine and ricin and in patients infected with bothriocephalus, an intestinal parasite that produces a haemolytic agent.

Haemolytic substances are said to be present in the intestine of anaemic patients that have chronic intestinal disorders, and recently a condition similar to pernicious anaemia has been

observed to occur following intestinal stasis. *B. aerogenes capsulatus*, which frequently inhabits the intestine of man, produces a haemolytic agent, and it is reported that they occur in increased numbers in the intestines of patients that have pernicious anaemia and that their number decreases during the remissions. The feeding of these bacteria in large numbers, or the intravenous injection of their products, produces in animals a condition quite like pernicious anaemia in man. Buckman and Horrall report that an haemolytic substance is present in the serum of pernicious anaemia patients.

Some observers believe that the stomach is in some way related to the cause, because of the high incidence of absence of acid in the stomach (achlorhydria) of patients suffering with this disease and because this disease sometimes occurs after total removal of the stomach. The absence of the acid in the stomach is said to favour the growth of bacteria that produce haemolytic poisons. After total gastrectomy in dogs a grave anaemia is found, which, however, has been controlled by the administration of iron and cod-liver oil. Although the more recent evidence seems to show that the change in the stomach is primary, it is commonly held to be secondary, as are the changes in the bone-marrow and nervous system, to the action of a toxin, irrespective of its source. (A. C. I.)

Treatment and Diet.—As regards treatment, Minot and Murphy of the Harvard Medical School showed in 1926 that very much may be done to stimulate blood-production and improve the patient's condition by feeding with liver. About half a pound of liver must be taken daily until the normal blood picture is restored which may be in a few weeks; subsequently the amount of liver may be reduced. In 1927 Cohn, Minot, Murphy and others found that a non-protein extract from liver containing the unknown factor could be used with equal success. These results have been confirmed in Great Britain, and in March 1928 the Medical Research Council, in a preliminary report, stated that extracts prepared by certain commercial drug firms had proved satisfactory. Certain other animal organs, as well as apricots, peaches and plums, are also of service. It has been debated whether iron must be in organic combination to be utilizable in blood regeneration or whether a simple inorganic salt (as ferrous carbonate) will suffice, but the evidence is that the form and quantity are not significant. Beef kidney and raspberries contain much more iron than do beef liver, apricots and peaches, but are much less effective in blood regeneration. Some unknown substance is supplied by the effective foods enabling the body to utilize the iron. Apricots, peaches and prunes are about as effective as bone marrow, pancreas and spleen; raisins and grapes rank lower, about on a par with brain tissue. The dried fruits are as effective as the fresh and in this connection are far superior to dairy products.

At the same time it may be noted that while diet may help, the liver treatment apparently affects the formation of blood alone and not the underlying condition on which the pernicious anaemia depends; the achlorhydria in particular is unaffected. Hence general measures must be undertaken besides the liver treatment. The source of the toxæmia should be looked for. Plenty of fresh air, sunlight and cod-liver oil are indicated. Dilute hydrochloric acid by mouth improves digestion. Removal of the spleen has been tried extensively, but without definite benefit. It is of great benefit, however, in splenic anaemia. Repeated blood transfusion is sometimes of great, though temporary value.

The benefits of liver diet for pernicious anaemia have been successfully demonstrated, both in America and Great Britain. The treatment was first suggested by G. R. Minot and W. P. Murphy of Harvard Medical school. Because a daily liver diet is intolerable to most patients, there have been extensive efforts to isolate the active principle in liver. As a result, liver extracts from the United States, Germany and Great Britain are now on the market. Since the extracts are soluble in water, a single dose, equivalent to nearly 30 oz. of whole liver, can be given a patient unable to take solid food. It has been demonstrated also that anaemics may obtain variety in apricots, peaches and prunes, either fresh or dried, and in certain other animal organs, such as brain tissue, bone-marrow, pancreas and spleen.

Other Forms of Anaemia.—There are other diseases of the blood and blood-forming organs, such as lymphosarcoma, Hodgkin's disease, chloroma, leucaemia and anaemia pseudoleucaemia of children, in which anaemia occurs. In these diseases the disturbance chiefly involves the white corpuscles, or leucocytes, and hence these diseases are not to be considered in a general discussion of anaemia. (X.)

ANAESTHESIA and ANAESTHETICS, terms used in medicine to describe a state of local or general insensibility to external impressions, and the substances used for inducing this state. In diseases of the brain or spinal cord anaesthesia is an occasional symptom, but in such cases it is usually limited in extent, involving a limb or a definite area of the body's surface and depends upon interference with nerve tracts or centres. Complete anaesthesia occurs in a state of catalepsy or trance.

On April 9, 1799, Sir Humphry Davy, while experimenting on nitrous oxide (the so-called "laughing gas"), discovered its anaesthetic properties, and described the effects it had on himself when inhaled with the view of relieving local pain. In 1818 Faraday showed that the inhalation of the vapour of ether produced similar anaesthetic effects, as was also shown by the American, John D. Godman (1822), James Jackson (1833), Wood and Bache (1834). These observations, in spite of the work of Henry Hickman in his famous pamphlet "A Letter on Suspended Animation" in 1824, remained scientific curiosities until March 30, 1842, when Dr. Crawford D. Long performed at Jefferson, Ga., an operation under ether. His statue now stands in the statutory hall in the Capitol, Washington, D.C. In December 1844 Dr. Horace Wells, a dentist of Hartford (Conn.), underwent in his own person the operation of tooth-extraction while rendered insensible by nitrous oxide. On Sept. 30, 1846, Dr. W. T. G. Morton, a dentist of Boston, following the suggestion of Dr. C. T. Jackson, employed the vapour of ether in private to procure general anaesthesia in a case of tooth-extraction, and thereafter administered it in cases requiring surgical operation with complete success. The first operation in public under ether was performed by Dr. J. C. Warren at the Massachusetts General Hospital on Oct. 16, 1846. On Dec. 19 of the same year Robinson, a dentist in London, and on the 21st Robert Liston, the eminent surgeon, operated on patients anaesthetized by ether; and the practice soon became general both in Great Britain and on the continent.

Sir James Simpson, in 1847, was the first to apply anaesthesia by ether to midwifery practice. On March 8, 1847, M. J. P. Flourens read a paper before the Académie des Sciences on the effect of chloroform on lower animals, and in November of the same year Simpson announced his discovery of the anaesthetic properties of chloroform. During the intervening period other drugs were found to possess anaesthetic properties. Of these ethyl chloride has come into prominence at the present time; nitrous oxide, too, which had been lost sight of, was reintroduced, to become the most popular anaesthetic in dental practice. Frequently, either alone or with oxygen, nitrous oxide is used in the preliminary stages of inducing ether anaesthesia.

The administration of the above-named drugs is by inhalation, and has to be continued throughout the operation, the reason being that all the drugs are as rapidly excreted as they are absorbed, especially by the lungs, and therefore no other method would be of any avail. On the other hand there are drugs which are sufficiently slowly eliminated to allow of an operation being performed between the moment of induction and that of recovery. The use of scopolamine and morphine in the production of "twilight sleep" for childbirth is an example. These drugs are injected with a hypodermic needle. Similarly, urethane produces a profound general anaesthesia but has only been used on the lower animals, as its

depressing effect on the respiratory centre contra-indicates its use in human beings.

Local Anaesthesia.—Much attention has been devoted to the discovery of methods by which the insensibility may be confined to the area of operation and the loss of consciousness avoided. But they have only lately been successfully applied to the severer operations. The earliest local anaesthetic was cold, produced by a mixture of ice and salt. The skin is now frozen by a fine spray of ether or ethyl chloride. The recovery, like that from any other frostbite, is very painful, and the time during which an operation can be done is very short; consequently this method has been very largely superseded by the use of drugs, particularly cocaine and its derivatives. Cocaine has by far the highest anaesthetic properties; it is, however, in certain individuals a most powerful cardiac depressant and has caused numerous fatalities. Eucaïne has now largely taken its place, though its anaesthetic properties are less; it is, however, less toxic, and can be sterilized by heat.

Spinal Analgesia.—The method of inducing analgesia by injecting solutions into the sheath surrounding the spinal cord was devised by Bier in 1898, but was not adopted to any great extent, until Fournieu discovered *stovaine* in 1904. The substances injected, by virtue of their specific action on nervous tissues, cause loss of painful sensations in the lower limbs and for a variable distance up the trunk. The injection is followed, generally within three to five minutes, by the production of analgesia, which lasts for a period varying from half an hour to two hours. Various substances have been used for the purpose of which the following are the chief: tropacocaine, stovaine, novocaine, cocaine, eucaïne and alypin. The chief points in favour of this method of producing analgesia are as follow: (a) The patient is not rendered unconscious, and is often able to assist at his own operation, such as by coughing or moving his limbs in any way as may be desired; (b) there are no troublesome after effects, such as nausea, vomiting and thirst; (c) surgical shock is considerably lessened, especially in such operations as amputations and severe abdominal emergencies; (d) the risk attending a general anaesthetic is avoided. The chief disadvantages are: (a) A severe form of headache may sometimes follow; (b) the paralysis of muscles. In a very few cases this has been permanent. The temporary paralysis of the muscles of respiration is apt to be a serious matter; (c) the uncertainty of the method, so that the analgesia is not always as complete as is desirable; (d) the analgesia for safety must be limited to a line below the level of the second rib in front. Finally, operations have been performed under a local anaesthesia produced by hypnotism (*q.v.*) but this is a method that can only be used on selected cases.

ANAGNIA (mod. Anagni); pop. (1921), town 6,274, commune 10,504; an ancient town of the Hernici, on a hill (1,558ft.) above the valley of Trerus and Via Labicana, Italy. Its position in a fertile district soon gave it importance, and it became the seat of the assembly of the Hernican towns. In the war of 306 B.C. it lost its independence. It was besieged by the Saracens in 877, but in the 11th century was a place of considerable importance, the Conti and Caetani being the chief families; Pope Boniface VIII., a member of the latter, was there made prisoner in 1303. The ancient city walls, built of rectangular blocks of porous limestone, still stand, much restored in places. Within the city the only ancient remains are some massive substruction walls on the hillside. The cathedral, constructed in 1074 at the summit of the hill, is externally plain; it has a fine Gothic interior.

ANAGRAM, the result of transposing the letters of a word or words in such a manner as to produce other words that possess meaning (Gr. *ἀνα* back, and *γράφειν*, to write). The construction of anagrams is an amusement of great antiquity, its invention being

ascribed without authority to the Jews, probably because the later Hebrew writers, particularly the Kabbalists, were fond of it, asserting that "secret mysteries are woven in the numbers of letters." Anagrams were known to the Greeks and also to the Romans, although the known Latin examples of words of more than one syllable are nearly all imperfect. They were popular throughout Europe during the middle ages and later, particularly in France, where a certain Thomas Billon was appointed "anagrammatist to the king" by Louis XIII. Dryden disdainfully called the pastime the "torturing of one poor word ten thousand ways," but many men and women of note have found amusement in it. A well-known anagram is the change of *Ave Maria, gratia plena, Dominus tecum* into *Virgo serena, pia, munda et immaculata*. Among others are the transposition of "Horatio Nelson" into "Honor est a Nilo"; and of "Florence Nightingale" into "Flit on, cheering angel." The pseudonyms adopted by authors are often transposed forms, more or less exact, of their names; the most remarkable pseudonym of this class is the name "Voltaire," which the celebrated philosopher assumed instead of his family name, "François Marie Arouet," and which is generally allowed to be an anagram of "Arouet, l.j.," that is, Arouet the younger. Some of the astronomers of the 17th century embodied their discoveries in anagrams with the design apparently of avoiding the risk that, while they were engaged in further verification, the credit of what they had found out might be claimed by others.

Another species of anagram, called "palindrome," is a word or sentence which may be read backwards as well as forwards, letter by letter, while preserving the same meaning; for example, the word "tenet."

ANAHEIM, a city of Orange county, California, U.S.A., 25 m. S.E. of Los Angeles. It is served by the Santa Fe, the Southern Pacific, and the Union Pacific railways, and by a network of highways. The population was 5,526 in 1920; and was 10,995 in 1930.

It lies in a fertile plain, irrigated from the Santa Ana river, which produces lemons and deciduous fruits, walnuts, berries, sugar beets, grain, and vegetables. The chief industrial products are dried and canned fruits, beet sugar, farm machinery, oil-well drilling supplies and denatured alcohol. Natural gas and crude oil are used for fuel.

Anaheim was the first of the settlements due to co-operative enterprise in Southern California. In 1857, 50 Germans organized an association in San Francisco, bought 1,165 acres of arid land, and prepared it for occupancy. The tract was then divided into 20-acre shares, which were distributed among the members by lot, with bonuses and rebates to equalize differences in value. This ended the co-operative aspect of the venture, except that the irrigating canal remained common property. The town was incorporated in 1870, and received a city charter in 1888. It has a city-manager form of government.

ANÁHUAC, a geographical district of Mexico, limited by the traditional and vaguely defined boundaries of an ancient Indian empire or confederation of that name previous to the Spanish conquest. The word signifies "country by the waters" in the old Aztec language; hence the theory that Anáhuac was located on the sea coast. Anáhuac has been described as all the plateau region of Mexico, with an area equal to three-fourths of the republic, and extending between the eastern and western coast ranges from Rio Grande to the Isthmus of Tehuantepec. But it properly is the great plateau valley in which the city of Mexico is located, between 18° 40' and 20° 30' N. lat., about 200m. long by 75m. wide, with an average elevation of 7,500ft., and a mean temperature of 62°. The existence of the name in southern Utah, United States, and on the Gulf coast of Mexico, has given rise to theories of other locations and wider bounds for the old Indian empire.

ANAKRUSIS, from the Greek, meaning literally "up beat," has been defined in poetry as, "a syllable at the beginning of a verse before the just rhythm"; otherwise, an introductory weak accent preceding a strong one. In music the term is similarly applied to the notes on the weak beats of the bar, more especially to that on the last beat, preceding the strong one on the first beat

of the following bar, and constituting very frequently an apparently incomplete bar when occurring at the beginning of a composition.

ANALCIME, a common mineral of the zeolite group. It crystallizes in the cubic system, the common form being the icositetrahedron (211), either alone or in combination with the cube (100). The crystals are often perfectly colourless and transparent with a brilliant glassy lustre, but some are opaque and white or pinkish-white. The hardness is 5 to $5\frac{1}{2}$, and the specific gravity 2.25. Chemically, analcime is a hydrated sodium and aluminium silicate, $\text{NaAlSi}_3\text{O}_8 \cdot \text{H}_2\text{O}$. Before the blowpipe the mineral readily fuses with intumescence to a colourless glass. It is decomposed by acids with separation of gelatinous silica. Analcime usually occurs, associated with other zeolitic minerals, lining amygdaloidal cavities in basic volcanic rocks such as basalt and melaphyre. The Tertiary basalts of the north of Ireland frequently contain cavities lined with small brilliant crystals of analcime. Larger crystals of the same kind are found in the basalt of the Cyclopean islands, Sicily. Large opaque crystals of the pinkish-white colour are found in cavities in melaphyre at the Seisser Alpe in southern Tirol.

ANALGESIA is the name given to the loss of the sensation of pain, and is due to an interruption of the nervous pathway between skin and brain. Different forms of sensation from one area of skin, such as touch, temperature, and pain, travel to the spinal cord by different nerve fibres in the same nerve bundle. Hence any injury or disease affecting such a nerve would abolish all forms of sensation in the area supplied by it. However, when the sensory nerves reach the spinal cord their fibres separate and pursue different courses on their way upward to the brain. Thus it is possible for certain forms of sensation to be lost, while others are preserved, in diseases which affect only certain areas in the spinal cord. Since the sensations of pain and temperature travel the same path, they are usually lost together. Diseases of the cord which may cause analgesia without loss of the sensation of touch are tabes dorsalis, syringomyelia and tumours of the cord. Analgesia may also be a manifestation of hysteria.

ANALOGY. Originally the general term *analogy* appears to have been used in the sense of "proportion," and so confined to quantitative relationships. Thus, for instance, the relation between three and four would be described as analogous to that between nine and 12; or, more generally, the relation between x and y would be described as analogous to that between nx and ny . Analogy in this sense could obviously serve as a basis for reliable inferences. In the solution of equations of many kinds it is usually possible to determine (that is, to infer) the value of an unknown quantity when its relation to a known quantity is given. Hence the early vogue of the expression "inference (or reasoning) from analogy." In mathematics, however, the term analogy has been displaced by the term proportion, except in the expression "Napier's Analogies" still used in spherical geometry.

Side by side with this *quantitative* application of the term *analogy* we find, already in Aristotle, a *qualitative* use of it. In its quantitative sense of "proportion," analogy designated similarity or identity of quantitative relationship between two pairs of terms; in its qualitative use the term analogy indicates similarity in *any kind* of (non-quantitative) relationship between two sets of terms. In this wider sense the term is very common, and the thought which it expresses is applied very extensively, especially in popular modes of thought and of expression. This is evident from the frequent use of metaphor, which is but one example of analogy. For instance, the metaphorical use of the term "sweet" in the phrase "a sweet melody" is an abridgment of the analogy that "this melody affects the ear in the same pleasing way as sweet things affect the palate." Similarly the expression "Mother Country" implies the analogy that "the relation of a country to its colonies is like that of a mother to her children." Another familiar group of analogies may be seen in the way in which people inflect new terms (or terms which are new to them) on the model of the known inflections of other terms—e.g., "looped" is to "loop" as "looked" is to "look." Or, again, the names of certain organs of animals are often based on analogies—the so-called

"wings" of butterflies are structurally very different from the wings of birds, but their function in relation to the butterfly (viz., in enabling it to fly) is essentially like that of the wings of birds, and so these otherwise different organs of butterflies and of birds are called "analogous organs." Similarly, all kinds of new inventions are frequently given names based on analogy—"air-ships," e.g., are machines which do in the air what ships do in the water. And so on.

As appears already from the case of metaphors, from the case of "analogous organs" in biology, and analogous constructions in grammar, the *similarity of relationships* between pairs or sets of terms is apt to appear as a *similarity between the terms* or things themselves. And so the term "analogy" has come to be extended to *similarities* generally, excepting that close similarity which exists between members of the same recognized class of objects in respect of those qualities which are regarded as characteristic of that class. Thus, e.g., one would not think of potatoes as being "analogous" to one another—they are too much like one another for that. Similarly with apples. But, as is evident from their French and German names, potatoes are regarded as "analogous" to apples.

The Psychology of Analogy.—Psychologically or educationally the importance of analogy lies in the fact that it is a very common form of apperception (*q.v.*), a way of assimilating new and strange objects to older and more familiar ones—a way of profiting from past experience for the proper apprehension and treatment of new situations. Any new thing or occurrence is apt to appear familiar, and so to become acceptable, as soon as it can be linked up in some way with the general store of our already acquired ideas and beliefs. The only safeguard against the evils of so-called "reasoning from analogy," or "analogical argument," is a correct insight into the real nature and function of analogy considered from a logical point of view.

The Logic of Analogy.—As was pointed out above *quantitative* analogy is a basis of valid inferences. *Qualitative* analogy (the only type with which we are now concerned) is also frequently made the ground of inference. In fact some thinkers regard analogical reasoning as one of the fundamental types of inference together with deductive and inductive inference. Some, on the other hand, regard it as a species of deductive inference, and others as a variety of inductive inference. But at all events analogy is commonly accepted as a legitimate ground of inference when due care is taken. Now it is true that, as a matter of fact, people commonly do draw inferences from analogy. The real question, however, is whether such inferences can be regarded as conclusive or cogent. In other words, can reasoning from analogy ever be regarded as more than tentative, as equivalent to proof? This question must be answered in the negative for the following reasons. Reasoning from analogy usually assumes the following form: A certain phenomenon or a certain class of phenomena, say S, resembles a certain other phenomenon or class of phenomena, say Z, in some assignable respect, say M. Now Z is known to be P as well as M. It is accordingly inferred that S which resembles Z in respect of M also resembles it in respect of P; in other words, S is P. Now, strictly speaking, this conclusion could only be justified if it could be shown that M and P are connected by some law, either directly or indirectly. For unless M and P are so connected, the presence of M, in S or in anything else, may be entirely irrelevant to the question of the presence of P. That is why it is usually insisted that analogies or similarities must be *weighed*, not merely counted. For instance, the fact that light and sound resemble each other in respect of being transmitted through considerable distances is in itself no evidence that they also resemble each other in respect of having the same medium, or in respect of polarization, or even in respect of an undulatory form of transmission. If there is any connection between transmissibility and any of these other phenomena, it must be established independently. Now the question whether there is any connection between M and P, and if so, what it is, can only be decided by the usual methods of induction, not by mere analogy. The analogy may suggest *hypotheses* for inductive investigation; but it cannot *prove* anything. Analogy, in brief, is probably the most

fruitful source of suggestions, of hypotheses, that is, of *tentative inferences*, but it is not a type of *proof* at all. If an analogical inference is proved at all it is proved by inductive methods; if it is not proved or verified by inductive methods, it is not proved at all, and remains a mere suggestion, which may indeed be true, but is not yet established. In so far as an analogical suggestion proves fruitful it results in the inductive establishment of a connection between M and P, and so leads to the deductive application of this law of their connection to cases like S, etc. In other words, the analogy may eventually lead to both inductive and deductive proofs; but the analogy itself is neither inductive nor deductive, nor is it a proof at all; it is only an auxiliary to all these.

Of the value of analogy as an auxiliary to inductive investigation there can be no reasonable doubt. The history of science affords abundant evidence of this. A few illustrations may be adduced here. Descartes' perception of the analogy between algebraic and geometrical relationships has led to many important discoveries in modern mathematics. The observation of Jupiter and the Medicean satellites or moons led by analogy to the suggestion of the modern conception of the solar system. Newton's perception of the analogy between a falling apple and the moon led to the establishment of celestial gravitation. But analogy as such never goes beyond helpful *suggestion*—the actual results must be borne out by scientific methods. That is why in the more advanced sciences analogy plays a relatively unimportant part. The finished results are supported by inductive evidence; the analogies by which they may have been first suggested are no part of the evidence, and are of interest only as incidents in the mental history of the discoverer, in the history of the builder rather than in the structure of the building. On the other hand, in the less developed sciences analogy may play a prominent rôle. Much of so-called biological sociology consists in the exploitation of analogies between the structures and functions of animals and those of societies. The reason for the conspicuous part played by analogy in the less developed sciences, or stages of a science, is this: The first problem to be attacked in the history of a science is that of classification—the most helpful (intellectual) grouping of the phenomena to be investigated. Now some phenomena are obviously similar or obviously different (though not always really so). Others are not so, and it may require a keen eye for analogies to bring together things that really belong together but not obviously. In this way analogy may be an early stage in the recognition of a new and somewhat complex class of facts. The history of terms like "boycott" or "Hobson's choice" furnishes popular illustrations of this process. Franklin's study of lightning, and his careful enumeration of the analogies between lightning and electricity, may serve as a scientific illustration of the help that may be rendered by analogy in the classificatory stage, as well as in the later stages, of a science. It should be noted, however, that Franklin did not stop at the analogies between lightning and electricity, but proceeded to test the suggestion experimentally by means of his famous kite. In comparatively simple cases the transition from analogy to a new class concept is easy. After considering a few cases analogous to that of Captain Boycott, or to that of Hobson, one may readily get at the idea of social ostracism, or of apparent without real choice, respectively. But in more complex instances there is the danger that some important feature may be overlooked in the general description or definition of the type as such. Hence probably the legal tendency to cite cases and follow precedents rather than formulate general laws or principles—flexible analogies being regarded as safer than rigid formulae in certain types of legal and similar problems.

BIBLIOGRAPHY.—B. Bosanquet, *Logic*; J. S. Mill, *System of Logic* (1874, etc.); C. Sigwart, *Logic*; A. Wolf, *Essentials of Scientific Method*; see *APPERCEPTION*, and *SCIENTIFIC METHOD*. (A. Wo.)

ANALYSIS, in general, the resolution of a whole into its component elements; opposed to synthesis, the combining of separate elements or minor wholes into an inclusive unity. Both analysis and synthesis may be either purely mental or physical. The analysis and synthesis carried out in psychology, for instance, are purely mental. But even in physics, chemistry, etc., where these processes can also be carried out physically, the

mental analysis or synthesis generally precedes the physical in all well-planned experiments.

In grammar, analysis is the breaking up of a sentence into subject, predicate, object, etc. (an exercise introduced into English schools by J. D. Morell about 1852); so the analysis of a book or a lecture is a synopsis of the main points. The chief technical uses of the word, which retains practically the same meaning in all the sciences, are in (1) philosophy, (2) mathematics, (3) chemistry.

(1.) Logical analysis is the process of examining into the connotation of a concept or idea, and separating the attributes from the whole and each other. It, therefore, does not increase knowledge, but merely clarifies and tests it. In this sense Kant distinguished an analytic from a synthetic judgment, as one in which the predicate is involved in the essence of the subject. Such judgments are also known as verbal, as opposed to real or ampliative judgments. The processes of synthesis and analysis though formally contradictory are practically supplementary; thus to analyse the connotation is to synthesize the denotation of a term, and vice versa; the process of knowledge involves the two methods, analysis being the corrective of synthetic empiricism. In a wider sense the whole of formal logic is precisely the analysis of the laws of thought. Analytical psychology is distinguished from genetic and empirical psychology inasmuch as it proceeds by the method of introspective investigation of mental phenomena instead of by physiological or psycho-physical experiment. For the relation between analysis and synthesis on the one hand, and deduction and induction on the other, see *INDUCTION*.

(2.) In Greek mathematics the method of proving a proposition by resolving it into simpler statements already proved or else assumed as axiomatic. Pappus (c. 275), in his *Synagoge* or *Collection* (Bk. VII., "On the Treasury of Analysis"), gives the best extant Greek definition: "Analysis, then, takes that which is sought as if it were admitted and passes from it through its various consequences to something that is admitted as the result of synthesis." The process was probably used by the early Pythagoreans in the 5th century B.C., and was taught in Plato's school. Pappus speaks of it further as "a method which Plato, as they say, communicated to Leodamas, and by which the latter, too, is said to have discovered many things in geometry."

In the Renaissance period it came to be considered as the method of solving problems by means of equations, as in analytic geometry (*q.v.*). At present the word is used in a much more general way, being considered as including the theory of functions of real variables, infinite series, the differential and integral calculus, definite and multiple integrals, the calculus of variations, the theory of functions of complex variables, algebraic functions, elliptic and modular functions, special functions (Eulerian, Legendre's, Bessel's, hypergeometric, etc.), metrical and projective properties of quadric surfaces, algebraic curves and surfaces, algebraic configurations in general and infinitesimal and differential geometry. These topics are treated in various special articles, including *CURVE*; *FUNCTIONS*; *CALCULUS*, *DIFFERENTIAL* and *INTEGRAL*; and *DIFFERENTIAL GEOMETRY*.

(3.) In chemistry the word analysis was introduced by Robert Boyle to denote the determination of the composition of substances. (See *CHEMISTRY: Analytical*.)

BIBLIOGRAPHY.—For a detailed summary of the scope of modern analysis, with references to scientific literature see the *Catalogue of Scientific Papers* of the Royal Society of London, vol. i. pp. 233–653 (1800–1900). For later material see the *Jahrbuch über die Fortschritte der Mathematik* (annual summary of publications) and the *Revue Semestrielle*.

ANALYSIS SITUS (POSITION ANALYSIS). In this branch of mathematics shape and size are unimportant. The important property may be said, roughly, to be *proximity*; to state it in precise terms, we must introduce the idea of *limit point*. Let *S* denote the collection of all points in the Euclidean plane (*i.e.*, the plane studied in Euclidean plane geometry). Then a point, *P*, is called a *limit point* of a collection of points *M* if every circle whose centre is at *P* encloses at least one point of *M* which is distinct from *P*. It is easily seen from this definition that every

point of S is a limit point of S . Also every point of a line is a limit point of the collection of all points on that line. Similar statements may be made for all the ordinary figures of plane geometry. In *Analysis situs* we are interested only in those properties of figures which can be expressed in terms of collections, or *sets*, of points and their limit points—such properties are called the *topological* properties of the figures. A geometrical figure is regarded more in the sense of being a *point set* than as being a “figure.” (See POINT SETS.)

From another point of view it may be said that *Analysis situs* is interested only in those properties of figures or point sets which are not changed when the figures are subjected to continuous motion in a fluid medium. Thus, it is easy to conceive of a fluid motion carrying a circle into an ellipse and thence into a square, even though the areas enclosed by these figures differ greatly. From the standpoint of *Analysis situs*, then, there is no essential difference between these figures—the differences in their sizes and shapes are unimportant. However, the idea of continuous fluid motion is not precise enough for an exact characterization of *Analysis situs*. In order to make the idea implied by the illustration more exact, we introduce the idea of *homeomorphism*, and here we are led again to the idea of limit point.

Homeomorphism.—Two point sets, A and B , are said to be *homeomorphic* if their points can be made to correspond in a one-to-one manner, those of A to those of B , so that if A_1 is any set of points in A having a point P_1 in A as a limit point, then the set, B_1 , of corresponding points in B has the point P_2 of B which corresponds to P_1 as a limit point, and conversely. In figure 1 consider the sets A , B and C . In A the set of points consisting of a_1, a_3, a_5, \dots , that is, all a 's having odd subscripts, has a as a limit point (we suppose that there are infinitely many points in A , the subscripts of the a 's running through the entire set of positive integers); similarly the set of a 's with even subscripts has a as a limit point. It may be said that these two sets converge to a from two opposite directions. In B there are three sets of points, consisting of (1) b_1, b_4, b_7, \dots , (2) b_2, b_5, b_8, \dots , and (3) b_3, b_6, b_9, \dots , converging to b from three different directions. The set C contains a set of points consisting of c_1, c_2, c_3, \dots , which has two limit points, d_1 and d_2 . Now A and B are homeomorphic, since by simply making every a_n correspond to the b_n of the same subscript, and a to b , the definition is satisfied. But neither A nor B is homeomorphic with C , for no correspondence can be set up between

FIG. 1.—HOMEOMORPHIC POINT SETS

A and C , say, which will satisfy the definition. If both d_1 and d_2 were made to correspond to a , then the latter part of the definition would be satisfied, but then the correspondence would not be one-to-one.

It can be seen that squares, circles, ellipses, triangles and polygons are all equivalent in the sense that they are homeomorphic. And if we substitute the precise notion of homeomorphism for that of fluid motion, we can say that *Analysis situs* is interested only in those properties which are common to all figures that are homeomorphic. It might be asked, after observing that the geometric figures just mentioned do not have a common shape or a common size, and hence seem to have very little in common, just what properties are left to be studied? It may seem that there is very little left to be studied. To show that this is by no means the case, will be the purpose of the remainder of this article. We shall not attempt to cover all of the various aspects of *Analysis*

situs, but take up only sufficient of the elementary notions to accomplish our purpose.

Connectedness.—A glance at the various familiar figures of plane geometry, such as the line, the triangle, the circle and the polygon, impresses one with a general property of such collections of points, namely their *connectedness*. Thus, a straight line, although it is made up of points, is somehow to be thought of as a connected thing, in the sense that if it were possible to pick up the line with one's hands it would not fall apart, but would hang together like a piece of twine. It was an early problem of *Analysis situs* to express in some precise way just what this connectedness of sets of points is. The most successful attempt at this is embodied in the so-called Lennes-Hausdorff definition (1) (2). A point set M is *connected* if it is impossible to separate it into two sets A and B such that A and B have no common points and such that neither A nor B contains a limit point of the other. It can be shown that all of the geometrical figures referred to above are connected according to this definition. Thus, no matter how we divide the set of all points on a line into two groups, at least one of these will contain at least one limit point of the other. It is easy to prove that if two point sets are homeomorphic and one of them is connected, then the other is connected; *i.e.*, connectedness is a common property of homeomorphic point sets.

Recent researches have demonstrated, however, that the connectedness implied by this definition is not as strong as the “connectedness” one has in mind when thinking of a line as the geometric analogue of a piece of twine. If a point is removed from a line, the remainder is separated into two portions each of which is itself connected. If we remove a point from a circle what is left is still connected; *i.e.*, no point of a circle *disconnects* the circle. But the existence has been established (3) (4) of certain sets of points in S , which, though they are connected according to the above definition, can be totally disconnected by the omission of single points. That is, there exists, in S , a connected point set M containing a certain point P which, if omitted from M , leaves no connected portion in M whatsoever.

Closed Sets and Continua.—However, the set of all points on a line has a property which the set of points M just referred to does not have; thus, if P is a limit point of the set, L , of all points on a straight line, then P must be a point of L . For if P were not a point of L , then, denoting by d the perpendicular distance from P to the line, clearly a circle with centre at P and radius equal to one-half of d would enclose no points of L and hence P could not be a limit point of L . The property of containing all limit points has been found to be an important one in *Analysis situs*, and is given a special name; if a set of points contains all of its limit points, it is said to be *closed*. A point set which is both closed and connected and which contains more than one point is called a *continuum*. All ordinary geometrical figures are therefore continua, and it is easy to show that if one of two homeomorphic point sets is a continuum, then the other is a continuum. The set M referred to in the preceding paragraph is not only not closed but fails to contain any continuum whatsoever.

FIG. 2.—LOCALLY CONNECTED POINT SETS

It is natural for the mathematician, having generalized from the figures of geometry to the continuum, to investigate the nature and possible structure of continua from a topological standpoint. Perhaps the simplest continuum is the *arc*, which is a set of points that is homeomorphic with a straight line interval. Another simple continuum is the *simple closed curve* which is a set of points that is homeomorphic with a circle. Both arcs and simple closed curves are special cases of *continuous curves*, which form a much more general class of continua. In order to characterize those continua which are continuous curves we introduce the idea of *local connectedness*.

Local Connectedness.—A set of points M is said to be *locally connected* at a point P provided that if C is any circle with centre at P there exists another circle, K , with centre at P , such that if Q is a point of M interior to K , then there is some connected set in M which contains both P and Q and lies wholly interior to C . In figure 2, let M be the set of all points on the broken line $ABPDE$, and C any circle with centre at P . The circle K can be so selected that it does not enclose any point of the straight-line interval DE , and hence if Q is any point of M within K , there is a connected portion of M joining P to Q without going outside of K . Hence M is locally connected at P .

A continuous curve is a continuum which is locally connected at every one of its points. All of the figures studied in geometry are continuous curves.

FIG. 3.—CONTINUA THAT ARE NOT CONTINUOUS CURVES

However, not all continua are continuous curves. In figure 3, let AA_1 be a straight line interval, whose length may be called 1 unit. Let A_2 be $\frac{1}{2}$ unit from A on AA_1 , A_3 be $\frac{1}{3}$ unit from A on AA_1 , and, in general, let A_n , where n is any positive integer, be at a distance $1/n$ unit from A and AA_1 . At every such point, A_n , erect a perpendicular, A_nB_n , to AA_1 , say 1 unit in length, and at A erect a perpendicular AB that is also 1 unit in length. Consider the set of points, M , consisting of all points on the straight line intervals AA_1 , AB , and A_nB_n (for every n). The set M is a continuum. It is not a continuous curve, however, because it is not locally connected at all of its points. For let P be a point of AB not coincident with A . Let C be a circle of radius r less than the distance from A to P . Then, no matter what circle K is selected with centre P , that circle, K , will enclose a point, Q , of some A_nB_n , say A_nB_n , and there will be no connected portion of M containing both P and Q and lying wholly within C .

For references concerning continuous curves, as well as for a description of some of their properties, the reader is directed to reference (5) of the bibliography at the end of this article. Here we shall close our discussion of those properties of point sets that are studied in *Analysis situs*, having selected only a few of the fundamental ones by way of illustration.

Applications.—The topological theory of manifolds, which is considered in a separate article (*see* MANIFOLDS), has important applications to nearly every branch of mathematics. The topology of other types of point sets has been quite recently evolved, and hence its applications have not yet been very extensive. The methods of *Analysis situs* are applicable to any set of points, however it be defined, so long as the notion of limit point is introduced. That is, the space studied is not necessarily S —it may be the set of points on a sphere, or in three-dimensional space, or in a very general space which is characterized by some set of axioms. (*See*, for instance, the Hausdorff axioms for a "topological space," in reference [1] in Bibliography below, p. 213). An important recent result has been what seems to be a satisfactory definition of the word "dimension"—a definition which not only yields 2 as the dimension number of S , but attaches definite integral dimension numbers to very general spaces. (For bibliography and general discussion, *see* reference [6] below.) The space studied need not, indeed, be a set of points at all, but a set of any sort of elements, so long as the notion of limit element is introduced.

In physics, topological methods and properties of point sets have been used in connection with certain problems in dynamics, and in particular with the problem of showing the impossibility of a certain kind of gas system (7). It seems a possibility that physicists and astronomers of the future will make increasing use of topological ideas.

In a recent work (8) of a philosophical nature—a work which seems to contain much of value not only for the mathematician and physicist but for the scientist in general, and which discusses

the relation between the world as it actually exists with the world as conceived by the physicist—it is interesting to note that the author has made use of quite recent results from the field of *Analysis situs*.

ANALYST, in modern times, a person who is professionally skilled in chemical analysis. He may be called upon in the discharge of his professional duties to analyse a very wide range of substances and report thereon with regard to their composition or their purity. Apart from private practitioners, analysts are employed by manufacturers, their duty being to exercise a constant watch over the processes of manufacture, to test the purity of raw materials used, and of the final product, and generally to engage in research work connected with the industry concerned. The services of analysts are constantly required in judicial enquiries, sometimes in purely criminal cases, sometimes in civil proceedings. In the case of criminal proceedings, the services of the local public analyst are usually employed, but in certain instances the official analyst of the British Home Office may be engaged. At the Government Laboratory, Clement's Inn Passage, London, W.C. a large staff of analysts examine foods, spirits, tobacco, etc., for import or excise duties and for other purposes. Under the Fertilisers and Feeding Stuffs Act, 1927, agricultural analysts are appointed by every county council, whose duty is the analysis of fertilisers and feeding stuffs.

A British public analyst is an analyst appointed by a local authority for the purposes of the administration of the Sale of Food and Drugs and closely allied Acts. He must be possessed of definite qualifications and be a competent authority on the microscopy and chemical analysis of all articles of food and drink. He must also have studied pharmacology and therapeutics.

The Society of Public Analysts was founded in 1874, and membership of the Society is open to any practising analytical chemist.

United States.—In the United States there are, in addition to numerous laboratories dealing exclusively with the control of plant operations, many consulting laboratories whose work is largely on analytical problems. Many of these laboratories deal in specialties, as foodstuffs, clinical, pathological and forensic analysis, fuel and water, and iron and steel. A large share of the consulting work of university laboratories deals with analytical problems. The organization of the U.S. Bureau of Agriculture in 1862 (becoming a department represented in the cabinet in 1889) included a chemist. This branch developed through the Bureau of Chemistry (1900) into the Bureau of Food, Drug and Insecticide Investigation (1927), which is charged with the enforcement of the Food and Drugs Act (1906). A number of branch laboratories assist in this work. Other analytical work on foods, drugs, fertilizers, soils, etc., is fostered by the Bureau of Chemistry and Soils. The official methods of analysis are those of the Association of Official Agricultural Chemists, with the exception of official drugs, the methods for the analysis of which are found in

the U.S. Pharmacopoeia. Supplementing the Bureau of Food, Drug and Insecticide investigation are the analytical laboratories and consulting chemists sponsored by the food commissioners of the several States under authority of their dairy, food and drug legislation. Most of this legislation is modelled after the Federal Food and Drugs Act. Agricultural analysis began in the agricultural experiment stations, organized in conjunction with the land grant colleges which were fostered by the Morrill Act of 1862. The experiment stations were provided for further by the Hatch Act of 1887. Other analytical laboratories of full or semi-public standing are those of the customs service, public health service, and the geological survey and State and municipal boards of health. Associations dealing largely with problems of analytical chemistry include the Association of Official Agricultural Chemists, the American Society for Testing Materials, the Association of Cotton-oil Chemists, the American Association of Cereal Chemists and the American Leather Chemists' Association. The majority of associations of this type publish their own journals and proceedings. Among societies of broader scope in which analytical procedures are given prominent attention are the American Chemical Society, the American Society of Biological Chemists, the American Public Health Association and the American Pharmaceutical Association.

ANALYTIC, of or pertaining to analysis; the method of separating a whole into its parts, the opposite of synthetic. For analytic *chemistry*, analytic *language*, etc., see the articles under the noun-headings. The title of *Analytics* was given by Aristotle to his treatises on logic.

ANALYTIC GEOMETRY. When Descartes first came upon the idea of co-ordinates, a link was made between the sciences of geometry and analysis. Now the connection has grown so close that the results of either can be passed over to the other by definite laws of interpretation. In what follows, a few leading ideas are set out in terms of plane geometry, most of which can be extended to three or more dimensions.

CARTESIAN CO-ORDINATES

Co-ordinates (*q.v.*) are numbers measuring certain geometrical quantities and used to fix the position of a point, *e.g.*, latitude and longitude fix a place on a map. It is possible to build up a geometry, which is not analytical, on the ideas of order and in-

FIG. 1.—CARTESIAN CO-ORDINATES, RECTANGULAR AND OBLIQUE

cidence alone, without introducing measurement; but in analytic geometry we assume that we can measure such things as lengths and angles, and compare two different things of the same kind by measuring them in terms of a common unit. The value of a co-ordinate may depend on the choice of units; or it may be independent of them if it is defined as a ratio of two quantities of the same kind.

The simplest plane co-ordinates are *rectangular cartesian*. Through a fixed point (*origin*) O , we take two lines (*axes*) OX, OY in fixed directions at right angles to each other. (In *oblique cartesian co-ordinates*, the axes are not rectangular, but inclined at a given angle α ; the conditions of a problem often make this an advantage.) We reach any point P of the plane by going from O a certain distance $x=OM$ along OX , and then another distance

$y=MP$ parallel to OY . The pair of numbers (x, y) are the co-ordinates of P . If x and y are positive, this procedure leads only to points in the first quadrant of the plane, bounded by the half-lines OX, OY . Points in the other three quadrants are reached by taking one or both of the steps OM, MP in the opposite direction; to these reversed steps we assign negative co-ordinates. A zero co-ordinate belongs to a point on one or other axis, and the co-ordinates of the origin are $(0, 0)$. Every point of the plane has a unique pair of real numbers as co-ordinates, and every pair of real numbers are the co-ordinates of a unique point.

Thus the point P , and its pair of co-ordinates (x, y) are equivalent data. Any length, or other geometrical quantity, that is fixed when the point P and the axes OX, OY are given, is fixed when x, y are given; thus, $OP^2 = x^2 + y^2$, and $\tan POM = y/x$. (If, instead of x, y , we are given $r=OP = \sqrt{x^2 + y^2}$ and $\theta = \angle POM = \tan^{-1} y/x$, then, since $x = r \cos \theta$, $y = r \sin \theta$, both x and y are determined; thus r, θ , are data equivalent to x, y , and can serve just as well in determining P ; they are called its *polar co-ordinates*.)

With any system of co-ordinates, the formula for the distance d between two given points P_1, P_2 is of great importance. Let the co-ordinates of P_1, P_2 have the suffixes 1, 2. Then, with rectangular cartesian co-ordinates,

$$d^2 = (x_2 - x_1)^2 + (y_2 - y_1)^2;$$

oblique cartesian co-ordinates,

$$d^2 = (x_2 - x_1)^2 + (y_2 - y_1)^2 + 2(x_2 - x_1)(y_2 - y_1) \cos \alpha;$$

polar co-ordinates,

$$d^2 = r_1^2 + r_2^2 - 2r_1r_2 \cos (\theta_2 - \theta_1).$$

The simplest analytic geometry of all is of one dimension; *e.g.*, when we deal with only one line and the points on it. Any point P can be specified by its distance $x=OP$, measured from a fixed origin O in terms of a fixed unit, which can be shown by marking the point A at unit distance from O , so that $OA = 1$. Then x is the one co-ordinate of P .

By far the most important assumption is that of a single point with the co-ordinate ∞ , at an infinite distance from O . This is required, for example, as the homologue of O in ordinary inversion, in which the point whose co-ordinate is x corresponds to the point whose co-ordinate is $1/x$.

Equations.—If we interpret the variables as the co-ordinates of a variable point P , an equation in x, y is a statement of the position of P . For example, the equation $x^2 + y^2 = a^2$ tells us that P is at a distance a from O , that is, P is some point on the circle centre O , radius a . This does not fix P , for one equation does not determine both x and y , but it relates x and y , and it limits P to lie on the curve. The equation holds between the co-ordinates of any point on the circle, and of no other point; it is called the *equation of the curve*.

Any geometrical property of the circle is a statement about P , true if, and only if, P lies on the circle; it has a corresponding equation in x, y which follows from the equation $x^2 + y^2 = a^2$. Suppose we want to prove that, if OX meets the circle in A, A' , then $PM^2 = A'M \cdot MA$. The expression of this desired result in terms of the co-ordinates is $y^2 = (a+x)(a-x)$, which is a simple algebraic deduction from $x^2 + y^2 = a^2$. Thus, in general, any equation in x, y represents a curve, whose properties, when expressed in terms of the co-ordinates of a general point lying on it, are precisely the analytical consequences of this equation.

Since there is, as a general rule, a very much more certain and obvious way of verifying an analytical deduction than of devising a geometrical proof, the translation into equations introduces *method* and helps to turn geometry, from an art into a science. One reason is that an algebraic expression has the property of *form*, which is more easily recognized than its geometrical equivalent. By the help of the conventions of the notation, the

FIG. 2.—RECTANGLE OF SEGMENTS IN A CIRCLE

expression is analysed, almost at first sight, into the components of its structure: variables and constants, terms, factors and indices.

The application of analysis to geometry saves effort by showing the direct way to success for soluble problems, and no less by showing certain others to be insoluble; it enables us to prove a negative. A particular figure may suggest wrongly that a certain property is true in general. In such a case, it is often quite hard to prove by pure geometry that the surmise does not always hold good. But when equations are written down expressing all the properties, both those given by hypothesis and those guessed from the figure, we can find out whether the second set can be deduced from the first or not. If they can, we may return more hopefully, and usually with some definite clue, to the search for a pure proof; if they are not deducible, we cease to waste our time on the matter. The classic example is the squaring of the circle by an Euclidean construction. For centuries, geometers were convinced that only a little more skill or luck was wanted for success, and no one was then in a position to assert that every conceivable attempt must fail. By the aid of analysis, that assertion is now proved. For this kind of special theorem, the analytical method is one of verification rather than discovery.

It is sheer folly to keep the two methods apart. There are occasions for using either alone, but we gain most power by using pure, algebraic and infinitesimal ideas and notations alongside, keeping ever present the relation between them, and the interpretation of each in terms of the others. "Every equation has its little meaning" is a better motto than "shut your eyes and write down the equations." For example, analytic geometry could hardly get going at all without relying on the theorem of Pythagoras, as was done tacitly earlier in this article in writing down $OP^2 = x^2 + y^2$.

Algebraic Curves.—The most important elementary property of cartesian co-ordinates is that an equation of the first degree in x, y represents a line, and conversely every line has an equation of the first degree. Thus:—

$y = \text{constant}$	is a line parallel to OX ,
$x = \text{constant}$	is a line parallel to OY ,
$ax + by = 0$	is a line through O ,
$ax + by + c = 0$	is a line parallel to the last, but does not pass through O if $c \neq 0$,
$x/a + y/b = 1$	is the line cutting off lengths a, b from the axes,
$y - b = m(x - a)$	is the line through the point A whose co-ordinates are (a, b) , making with OX the angle whose tangent is m . For different values of m , this can represent any one of the set of lines through A . The co-ordinates of the point of intersection of two given lines satisfy both their equations. Two independent linear equations in x, y always have one and only one solution, provided we admit infinite values; e.g., with the pair $ax + by = 0, ax + by + c = 0$. The corresponding geometrical convention is that two parallel lines intersect in one point at infinity.

A quadratic equation represents a *conic* (see CONIC SECTIONS), the simplest being the circle $x^2 + y^2 = a^2$. It illustrates the unity of mathematics that the same curves should be the first to present themselves naturally along the two lines of approach. The co-ordinates of the intersection of a line and conic satisfy a linear and a quadratic equation; their determination depends on the solution of the eliminant, a quadratic equation in one variable. Now a line may meet a conic in two different real points, or touch it at one point or pass clear of it. The conditions are the same as that the corresponding quadratic equation may have real and distinct, or equal or imaginary roots. It is therefore convenient to speak of the intersections of the line and conic as always two in number, being real or coincident or imaginary.

If the equation of a curve in cartesian co-ordinates is algebraic and not transcendental, its degree, in the co-ordinates jointly, is called the *degree of the curve*. The co-ordinates of the intersections of a curve of degree n and any line depend on an elimi-

nant of degree n ; there are n such intersections, real or imaginary, finite or coinciding with the one point at infinity on the line. The fundamental theorem about such curves is that two algebraic curves of degrees n_1, n_2 have $n_1 n_2$ points of intersection; as we have just seen in the case when one is a line, $n_2 = 1$. Thus two conics meet in four points.

A common application of co-ordinates in subjects such as engineering or statistics is to show the variation of two connected quantities by means of a graph. This is not really analytic geometry, but rather its converse; not the use of analysis to increase our geometrical knowledge, but the use of geometry to illustrate some analytical knowledge. We can draw a graph whenever we can calculate one co-ordinate directly in terms of the other, and its equation has the form $y = f(x)$.

OTHER TYPES OF CO-ORDINATES

A co-ordinate need not be a distance. In one dimension, a point P of a line can also be specified, for example, by choosing two points of reference A, B , and determining P by the co-ordinate $\lambda = AP/PB$, which is a ratio of lengths, not a length itself. Points within the segment AB have positive co-ordinates, 1 being that of the midpoint, the points beyond A and beyond B have negative co-ordinates of absolute values < 1 and > 1 respectively, and the co-ordinates of A, B and the point at infinity are 0, ∞ and -1 . Again, we can choose three points of reference A, B, C , and define P by the value of the cross ratio

$$\xi = \frac{AP}{PB} \bigg/ \frac{AC}{CB},$$

which is of advantage in dealing with projections.

In plane problems not concerned with actual measurements, the most useful co-ordinates are *areal*. Instead of two independent co-ordinates, each point has three, connected by a simple identity. We refer to a fixed triangle ABC , and the co-ordinates of P are ratios of areas of triangles and are independent of the units of length and area:

$$x = PBC/ABC, \quad y = PCA/ABC, \quad z = PAB/ABC,$$

with the sign convention that x is positive or negative according as A and P are on the same side or opposite sides of BC . Wherever P lies, we have identically

$$x + y + z = (PBC + PCA + PAB)/ABC \equiv 1.$$

The three co-ordinates are equivalent to two independent quantities only, which we could take to be x and y , but it is more convenient to leave them an unspecified pair of the ratios $x : y : z$, for the following reason. Since we may write $x + y + z$ for 1, we can alter the dimension, in x, y, z jointly, of any term without altering its value. We thus arrange that every equation is homogeneous in the three variables; then it alters none of the work if we replace x, y, z by three other quantities having the same ratios, say, ax, ay, az , and these can be taken to be the co-ordinates of P , instead of x, y, z . The sum of these new co-ordinates is a instead of 1, but this does not matter, since we need not use the identity again; the two independent ratios are the same as before. To this extent, the areal co-ordinates of a point are not unique, but each set of co-ordinates always determines a unique point.

The expression for distance in this co-ordinate system is complicated, involving the sides and angles of the triangle of reference, but it is still true that the equation of a line is of the first degree and conversely. If this is to hold without exception, the particular linear equation $x + y + z = 0$, which contradicts the fundamental identity for the co-ordinates of a finite point, must be interpreted as a line altogether at infinity, the locus of the points at infinity on each of the other lines of the plane. There are other systems of homogeneous co-ordinates, in which also linear equations represent lines, the line at infinity having a less simple form; for example, *trilinear co-ordinates*, which are the perpendicular distances of P from the sides of the triangle of reference.

The cartesian co-ordinates (a, b) of a point P can be regarded as specifying the two lines $x = a$ and $y = b$, intersecting at P ,

selected from the two families of lines parallel to the axes OY , OX respectively. We have a more general type of co-ordinate, replacing these two families of lines by other curves; e.g., two families of concentric circles, with fixed centres A_1 , A_2 and varying radii. Then if P is given, it determines the values (ρ_1 , ρ_2) of the radii for which the two circles, one from each family, intersect at P . These are *bipolar co-ordinates*. If ρ_1 , ρ_2 are given, P

FIG. 3—DISTANCE BETWEEN TWO POINTS IN RECTANGULAR, OBLIQUE, AND POLAR CO-ORDINATES

is not uniquely determined, for the two circles through P have another real intersection, the reflection of P in the line A_1A_2 . In some connections, for example, if we are interested in one-half only of the plane, this is no bar to their use.

In each of these systems, all the co-ordinates are elements of the same kind. This is not essential; of the two polar co-ordinates, one is a length and one an angle. In other systems, the interpretation of a co-ordinate by itself is less simple than that of some combination. For example, one of the circles, which determine P in the bipolar system, has a cartesian equation of the form $x^2 + y^2 + 2ax + 2by = \lambda$, where a , b are constants depending on the fixed centre, and λ is a parameter which can serve instead of ρ_1 as a co-ordinate of P , since it determines the circle equally well. Here λ itself is the negative square of the tangent from the cartesian origin to the circle through P ; whereas the combination $\sqrt{(a^2 + b^2 + \lambda)}$ is the radius ρ_1 .

TRANSFORMATIONS

A co-ordinate is always measured with respect to a fixed origin or base or *frame of reference* of some sort. The analytical method gains by choosing the frame so as to simplify the treatment of the problem in hand, and in particular to take advantage of any symmetry. If there is one fixed point outstanding among the data, we may take this as cartesian origin. If there is a pair of equal importance, we may put the origin midway between them, and take the axis of x to join them, so that their co-ordinates are $(a, 0)$, $(-a, 0)$. If the problem is descriptive and involves a triangle, areal co-ordinates are indicated, and so on. For example, the property of the existence of the centre of gravity of a triangle, where the medians concur, becomes the mere statement that there exists a point whose areal co-ordinates are $(1, 1, 1)$.

We often need to change the frame of reference in the middle of a piece of work, and to express, in terms of the new system, any result already obtained in terms of the old co-ordinates. We must find expressions to substitute for each of the old co-ordinates separately, that involve the new co-ordinates and the constants determining the new frame of reference in relation to the old, but that do not involve the other one of the old co-ordinates. Thus the change from cartesian to polar co-ordinates, with the same origin and axis, is effected by $x = r \cos \theta$, $y = r \sin \theta$; and the change back again by $r = \sqrt{(x^2 + y^2)}$, $\theta = \tan^{-1} y/x$.

If we change from one rectangular frame of axes XOY to another $X'O'Y'$, we must know the co-ordinates $OA = a$, $AO' = b$ of the new origin O' referred to the old axes, and also the angle ϕ between the $O'X'$ and OX . Then if P is any point, and (x, y) , (x', y') its two pairs of co-ordinates, we find:

$$x = a + x' \cos \phi - y' \sin \phi, \quad y = b + x' \sin \phi + y' \cos \phi;$$

and if, at a later point in the work, we wish to translate results involving x' , y' into terms of the old co-ordinates we must use

$$x' = (x - a) \cos \phi + (y - b) \sin \phi, \\ y' = -(x - a) \sin \phi + (y - b) \cos \phi,$$

so as to eliminate the new co-ordinates.

If x' , y' are point co-ordinates in a plane, π' , and we make a substitution of the form

$$x' = f_1(x, y), \quad y' = f_2(x, y), \quad (1)$$

and interpret x , y as point co-ordinates in another plane π , then to any point P of π there corresponds the particular point P' of π' , homologue of P , whose co-ordinates are given by (1). If P moves and describes a curve k , then P' also moves and describes a curve k' , which corresponds to k , and whose properties can be deduced from those in the other plane. If P' is a given point of π' , there corresponds to it all the group of points whose co-ordinates satisfy (1), when in these equations we regard x' , y' as known and x , y as unknown. If P' lies on k' , in general only one of the group lies on k . Thus the two curves are transformed into one another so that each point of either corresponds to one and only one of the other. In particular, if (1) are such that they can be solved in the same form $x = f_1'(x', y')$, $y = f_2'(x', y')$, then there is a 1, 1 correspondence between all the points of the two planes, and not only between the points of the two curves.

The degree of a 1, 1 plane transformation is that of the curve in either plane which corresponds to a line in the other. If the two planes are identical, we have a transformation of the plane into itself. The simplest examples are translation, rotation, similarity and their combinations, which are all linear transformations, and inversion, which is quadratic. The last transforms P into the point P' of OP such that $OP \cdot OP' = \text{constant}$; it can be expressed by

$$x' = \frac{a^2 x}{x^2 + y^2}, \quad y' = \frac{a^2 y}{x^2 + y^2},$$

and the reverse equations have the same form. Two different maps of the same region of the earth's surface are 1, 1 transformations of it and of each other. For example, one may show the whole world as a rectangle, and the other may show it as a pair of circles. The shapes of Australia are quite different; but each spot within one map corresponds to one and only one within the other. This is not true of points on the boundaries, which are exceptional. (See CONFORMAL REPRESENTATION.)

So far we have considered co-ordinates of points only; but any variable geometrical object can have co-ordinates, for example, the lines or circles of the plane. If x , y are the cartesian co-ordinates of a point P , the equation of any line l can be taken in standard form $\alpha x + \beta y = 1$, where α , β are the reciprocals of the intercepts which l makes on the axes. For different values of α , β , we can identify l with any given line: thus α , β may be taken as the *line co-ordinates* of l . If x , y are constants and α , β variable, the equation expresses that the variable line l passes through the fixed point P , and is the equation of the point in line co-ordinates. Just as any equation in point co-ordinates defines a continuous set of points lying on a locus, which is a line if the equation is of degree 1, so an equation in line co-ordinates defines a continuous set of lines all touching a curve, called an *envelope* from this point of view, which is a point if the equation is of degree 1. For this reason, line co-ordinates are often called *tangential co-ordinates*. In general, the degree of the envelope is the number of tangents, real or imaginary, which can be drawn to the curve from any given point. This number is called the *class* of the curve, and is equal to the degree n if $n = 1$ or 2, but for $n \geq 3$, the two are not generally the same.

Any piece of analysis, which has a geometrical meaning when a pair of variables are taken to be the co-ordinates of a point, has another meaning when the same variables are taken instead to be the co-ordinates of a line; and all such geometrical theorems occur in pairs, *dual* to each other. Corresponding to any plane figure built up from points and the lines joining them, there is a dual figure, built up in the same way from lines and their points of intersection. For any statement about the one, there is a statement about the other, exactly the same except that points

and lines are replaced by lines and points; and the analytical proofs are the same, except for the definitions of the symbols. The perpendicular distance of the line l from O is p where $1/p^2 = \alpha^2 + \beta^2$; the line equation $\alpha^2 + \beta^2 = 1$ is satisfied by any line at unit distance from O and the envelope represented by this equation is the circle of unit radius centre O . The same equation

FIG. 4.—CHART SHOWING THE CHANGE OF RECTANGULAR AXES

in point co-ordinates represents the same circle, which is a self-dual figure.

THREE OR MORE DIMENSIONS

In three dimensions, a point requires three co-ordinates; a single equation between them represents a surface. For a curve, two equations at least are necessary; since each by itself gives a surface, the points whose co-ordinates satisfy both equations are those lying on both surfaces, and the curve represented is their complete intersection. If this total intersection breaks up into distinct curves, to represent one curve k apart from the other, we use the equation of another surface which passes through k but not through the residual curve. There may or may not exist two surfaces whose total intersection is k ; if not, k cannot be represented by less than three equations. Thus the intersection of two quadrics can consist of a line and a twisted cubic curve. We can represent the line alone by the equations of two planes passing through it, for these have no other common curve; but to express the cubic we use the equation of a third quadric through it, meeting the first two in different residual lines.

In space, the general bilinear equation in two sets of three variables $\alpha x + \beta y + \gamma z = 1$, according to the way we interpret it, represents either a point or a plane, and these elements are dual to each other. A line may be regarded either as the intersection of two planes or as the join of two points, and, in either point or plane co-ordinates, can be represented by two linear equations. The whole set of lines in space is a fourfold infinity, and a line requires four independent or five homogeneous co-ordinates. It is more symmetrical and convenient to use a set of six homogeneous co-ordinates, which are connected by one quadratic identity, and whose ratios involve four independent quantities. If the line is defined as the intersection of two planes whose point

equations are $a_1x + a_2y + a_3z + a_4 = 0$, $b_1x + b_2y + b_3z + b_4 = 0$, the co-ordinates of the line are the six quantities $p_{23}, p_{31}, p_{12}, p_{14}, p_{24}, p_{34}$, where $p_{ab} \equiv a_a b_b - a_b b_a$, connected by the identity:—

$$p_{23}p_{14} + p_{31}p_{24} + p_{12}p_{34} = 0.$$

As far as the algebra is concerned, there is no essential difference, except in complexity, between three dimensions and any higher number. Most people's imagination can deal with line, plane and space, and stops short there; but analysis is more than imagination. With proper extensions, the ideas and language suitable to the lower dimensions, and partly supplied by everyday life, can be carried on. We agree to call a set of n numbers the co-ordinates of a point in a space of n dimensions, the series of sets satisfying one linear equation a *hyperplane*, and so on. This

may seem to be geometry in name only; but properties of lower space suggest valid and interesting extensions in higher space, that retain their geometrical tinge, and, conversely, many results in ordinary space have been suggested, or their mutual relations illuminated, by work in higher dimensions, which, to a specialist imagination, is as geometrical as the lower ranges are to everybody. Moreover, though it is not easy to imagine a fourfold infinity of points, we are familiar with the higher orders of infinity in other objects, for example, all the lines of ordinary space, or all the conics in a plane. Thus the six homogeneous co-ordinates p_{ab} of a line in three dimensions may be interpreted as homogeneous co-ordinates of a point in space of five dimensions, lying on the quadric in that space whose equation is given by the quadratic identity satisfied by the p 's.

Mohrmann (Leipzig, 1903-15, in progress). (H. P. Hv.)

ANALYTIC JUDGMENT: see ANALYSIS.

ANALYTIC MECHANICS: see MECHANICS.

ANAMALAI HILLS (ANAIMALAI), a range of mountains in southern India, in the Coimbatore district of Madras, lying between $10^\circ 13'$ and $10^\circ 31'$ N., and between $76^\circ 52'$ and $77^\circ 23'$ E., forming a portion of the Western Ghats, south of the Palghat pass. They consist of a forest-clad and grassy tableland, with summits rising about 8,000ft.; Anaimudi peak (8,850ft.) is the highest in southern India. Their formation is metamorphic gneiss, veined with felspar and quartz, and interspersed with reddish porphyrite. The lower slopes yield valuable teak and other timber.

ANAMORPHOSIS (än'ä-mör'fō-sis) [Gr.], a deformation or distortion of appearance in drawing, the representation of an object as seen; for instance, as altered by reflection in a mirror; in botany, e.g., in the case of fungi or lichens, an abnormal change giving the appearance of a different species.

'ANAN BEN DAVID, a Persian Jew of the 8th century, and founder within Judaism of the sect of Qaraites (Karaites) which set itself in opposition to the rabbinic tradition. 'Anan ben David was an unsuccessful candidate for the dignity of Exilarch, and thus his opposition to the rabbanite Jews was political as well as theological. His secession occurred at a moment when the time was ripe for a reaction against rabbinism, and 'Anan became the rallying point for many opponents of tradition. (See QARAITEs.)

ANANDA, one of the principal disciples of the Buddha (q.v.), known as the beloved disciple of the Buddhist story. According to the commentaries he was the son of Amitodana, an uncle of the Buddha, entered the order in the second year of the Buddha's ministry, and in the 25th year was appointed his permanent attendant. He attained enlightenment just before the first council, of which he was a member, and at which he repeated the *Suttapiṭaka*. From canonical passages we learn that he persuaded the Buddha to allow women to become nuns, and he is represented as being interlocutor in many discourses and the actual author of several. A collection of verses is ascribed to him in *Thera-gāthā*, 1,018 ff. In the time of Fa Hien (4th century A.D.) his relics were worshipped at Vesālī, and special devotion was shown by the nuns owing to his having obtained their admission to the order. (E. J. T.)

ANANIAS, the Greek form of Hananiah or Ananiah, a not uncommon name in the Bible. Best known are (1) A member of the first Christian community who, with his wife Sapphira, was punished by Peter with sudden death for falsehood (Acts v. 1-10; cf. Josh. vii.). (2) A disciple at Damascus in the story of the conversion and baptism of Paul (Acts ix. 10-17, xxii. 12-16). (3) Son of Nedeaios (Jos. Ant. xx. 5. 2), a high priest who presided during the trial of Paul at Jerusalem (Acts xxiii. 2, xxiv. 1-5). He was high priest A.D. 47-59, and being accused of acts of violence was sent to Rome for trial (A.D. 52), but was acquitted by the

emperor Claudius. As a friend of the Romans he was murdered by the people at the beginning of the Jewish war of revolt.

ANANKE (*Ἀνάγκη*), Necessity or Fate personified. She is fairly prominent in posthomeric literature and theological speculation, particularly Orphic, but is definitely known to emerge into cult only at Corinth, where she was worshipped with *Bia* (Might, Force), see Pausanias, ii., 4, 6; there are one or two faint and dubious traces of her cult elsewhere. In literature, she is associated with *Adrasteia*, the *Moirai*, and similar deities. In Italy she does not appear to have been worshipped at all; the famous description of Necessitas (Ananke) in Horace, *Carm.* i., 35, 17, which makes her attendant on Tyche, is purely literary.

See Roscher's *Lexikon*, arts. Ananke, Necessitas.

ANANTAPUR, a town and district of India, in the Madras presidency. The town has a station on the Madras railway, 62m. S.E. from Bellary. Pop. (1921) 11,452. The district of Anantapur was constituted in 1882 out of the unwieldy district of Bellary. It has an area of 6,722 sq.m., and the north and centre form a high plateau, generally undulating, with large granite rocks or low hill ranges rising here and there above its surface. The south is more hilly, the plateau there rising to 2,600ft. above the sea. There is a remarkable fortress rock at Gooty, and a similar but larger rock at Penukonda, over 3,000ft. above the sea. Gooty fortress was a stronghold of the Mahrattas, but was taken from them by Hyder Ali. In 1789 it was ceded by Tippoo Sahib to the nizam, and in 1800 the nizam ceded the district of Anantapur with others to the British in payment for a subsidiary British force. The population in 1921 was 955,917. The principal crops are millet, rice, other food grains, pulse, oil seeds and cotton. There are factories for pressing cotton. Two railways traverse the district.

ANAPA, a port on the Black sea, north of Novorossisk, in the North Caucasian area of the R.S.F.S.R., 44° 58' N. 37° 18' E. It was formerly the scene of struggles between the Turks and Russians, until it became Russian in 1829. The fortifications were dismantled by the Russians during the Crimean war (1855). Pop. 13,320 (1926). The district has an experimental station for the encouragement of vine-growing and wine manufacture. Anapa is on the site of the ancient Gorgippia.

See M. I. Rostovtsev, *Iranians and Greeks in S. Russia*, with a bibl. (Oxford, 1922).

ANAPAEST, a metrical foot consisting of three syllables, the first two short and the third long (from Gr. *anapaistos*, beaten upwards). An anapaestic verse is one which contains only or mostly anapaests. In Greek tragedy, a passage in this metre denotes a marching movement of the chorus or an actor.

ANAPHRODISIACS are agents used to allay sexual desire. In general mild sedatives may accomplish this effect, such as bromides or luminal. Avoidance of a diet rich in meats and spices, and especially of intoxicating beverages, is important. Epsom salts in the usual purgative doses may be of service. Failing benefit by such means the advice of a psychiatrist may be helpful.

ANAPHYLAXIS, the state of exaggerated susceptibility of an animal or man to a biologically foreign protein which may follow a first injection of that protein. Richet, who first used the term in 1893, found that after two properly spaced injections of an animal with eel serum, the second dose produced a toxic (often fatal) effect, much greater than did the first dose. He considered it to be the reverse of prophylaxis such as results from the use of bacterial vaccines. Theobald Smith, and later, Otto, extended these observations, using guinea-pigs and horse serum in their experiments.

The Anaphylactic Phenomenon.—If, for example, a guinea-pig be injected intravenously, subcutaneously or intraperitoneally with horse serum in an amount ordinarily not harmful, it becomes "sensitized" to horse serum, so that, if after ten to 14 days it be again injected with horse serum (*intoxicating dose*), there promptly result striking symptoms. The animal appears depressed and nervous, scratches its nose, shows a rapidly increasing difficulty in breathing, rapid pulse, and may die in a few minutes from respiratory failure. This symptom picture is called *Anaphylactic shock*. If the animal survive, it is for a time non-reactive to horse serum injections and is said to be *antianaphylactic*. After

some weeks this refractory state wears off and the animal will again suffer shock if injected. Sensitivity may be transferred from one animal to another (*passive anaphylaxis*) and a similar passive transfer occurs from mother to offspring.

Anaphylactic sensitivity is strictly specific; a guinea-pig hypersensitive to horse serum is not shocked by sheep serum. One can even distinguish by an anaphylaxis experiment between two such closely related proteins as duck and hen egg-albumin. A single animal may be sensitized to a number of proteins. Animals vary widely in the ease with which they may be rendered sensitive; guinea-pigs are easiest to sensitize, 0.000 001gm. of horse serum at times sufficing as the sensitizing dose, and 0.000 000 1gm. as the intoxicating dose. Rats are most difficult to sensitize; man is moderately so. The symptoms of anaphylactic shock differ in various species but are always characteristic for that species. The basis of symptoms is in each instance the contraction of involuntary muscle and an increased permeability of the capillary blood-vessel walls.

The Sensitizing Substances and Their Operation.—The substances to which animals may be sensitized (*antigens*) are protein in nature, with a large molecule, and optically active in solution. If a protein be racemized (rendered optically inactive by heat or sodium hydroxide) it can no longer produce sensitization or shock.

The method whereby anaphylaxis occurs is probably as follows. The body normally protects itself against foreign protein in the intestinal tract where the digestive ferments break down the protein beyond the stage of intermediate (at times toxic) split-products. If an intact foreign protein reaches the blood in any way, the same digestion is carried out (rather slowly) by the ferments of the blood and tissues. But so abnormal is this, that the body's protective mechanism is stimulated to produce an excessive amount of a specific ferment (*antibody*) which can act on that particular protein. When a second dose of that protein gets into the blood, there is an intensely rapid combination of protein (*antigen*) and ferment (*antibody*) with the production, through partial digestion, of a poisonous substance (*anaphylatoxin*).

There are reasons to believe that the reaction occurs largely within the body cells. Thus, sensitized animals after perfusion with normal blood can still suffer shock, and a strip of uterus muscle from a sensitized guinea-pig, after being thoroughly washed so as to remove all traces of blood, still contracts when exposed to the protein. The intracellular site of the reaction probably accounts for its intensity. The poisonous substance was at first supposed to be derived wholly from the second dose of foreign protein, but there is adequate evidence to show that much or all of it is derived from the proteins of the shocked animal.

Anaphylaxis in Man.—Typical anaphylactic shock is in rare instances seen in man. It has followed a second injection of horse serum (diphtheria or tetanus antitoxin, immune sera for treating scarlet fever, epidemic meningitis, pneumonia, etc.) given at a suitable interval after the initial dose. The symptoms are a feeling of apprehension, sneezing, nettle-rash, tickling in the throat, swelling of the face or more generalized swellings, violent asthma, rapid weak pulse; occasionally convulsions; death may ensue in a few minutes or hours. *Serum Sickness*, the symptoms which often follow even the first injection of a foreign serum, is probably anaphylactic in nature.

The presence in an individual of hypersensitiveness to a substance, horse serum for example, may be determined by suitable tests (see below), and this hypersensitiveness can be temporarily lessened by frequently repeated injections of increasing amounts of serum, beginning with extremely small, non-toxic doses. The patient can then be given the needed diphtheria antitoxin or other type of serum treatment with safety. In the actual attack a hypodermic injection of adrenalin may be life-saving.

Phenomena in Man Allied to Anaphylaxis.—Ten per cent of Caucasians are hypersensitive to a wide range of substances, usually protein in nature, that may be ingested (*foods*; e.g., egg, milk, shellfish, berries; *drugs*; e.g., quinine) or inhaled (*pollens*; *animal emanations*; e.g., feathers, hair, dandruff; *dusts* of organic origin; e.g., flour, wood dusts, house dust). Even tiny

amounts of these substances, in susceptible subjects, provoke a variety of diseases (*q.v.*): asthma, hay fever, *Urticaria*, some forms of eczema, etc. Some of the phenomena of infections and parasitic infestations may be due to acquired hypersensitiveness to proteins of bacterial or parasitic origin (skin reactions to tuberculin and luetin, urticaria in *Ascaris* and *Echinococcus* infestations, etc.).

Hypersensitiveness of an individual to a protein may be demonstrated by applying the protein to an abrasion in the skin or injecting it in solution into the skin: swelling and redness at the site of contact indicate sensitiveness to that substance. Such *skin testing* is used in the diagnosis of suspected hypersensitiveness. The treatment of human hypersensitiveness is (1) Avoidance of the offending substance; *e.g.*, omission of a food from the diet; substituting a cotton pillow for the feathers to which the patient is sensitive; and (2) Creation of tolerance for the offending substance by repeated administration of increasing amounts of the substance, beginning with small non-toxic doses. Avoidance gives better results than does the second method.

Though human hypersensitiveness is probably closely allied to anaphylaxis, it differs therefrom by being usually a natural, not an acquired state; it tends to be hereditary, following the Mendelian law; it is not usually accompanied by presence of specific blood antibodies of the precipitin type (*see* IMMUNITY); it may exist towards non-protein as well as protein substances, etc.

The terminology of the entire subject is somewhat confusing. The term *allergy* was introduced by von Pirquet to include all manifestations of human hypersensitiveness. The term *atopy* has been applied by Coca to the natural (inherited) type of human hypersensitiveness. The term *anaphylaxis* is usually restricted to those instances of human hypersensitiveness which follow an initial sensitizing dose, and conform in other respects to hypersensitiveness as seen in laboratory animals.

Detailed discussions of the subject will be found in the standard text-books on immunology, pathology and internal medicine. (R. A. KN.)

ANARCHISM, the name given to a principle or theory of life and conduct under which society is conceived without government (from Gr. *ἀν-* and *ἀρχή*, without authority)—harmony in such a society being obtained, not by submission to law, or by obedience to any authority, but by free agreements concluded between the various groups, territorial and professional, freely constituted for the sake of production and consumption, as also for the satisfaction of the infinite variety of needs and aspirations of a civilized being. In a society developed on these lines, the voluntary associations which already now begin to cover all the fields of human activity would take a still greater extension so as to substitute themselves for the State in all its functions. They would represent an interwoven network, composed of an infinite variety of groups and federations of all sizes and degrees, local, regional, national and international—temporary or more or less permanent—for all possible purposes: production, consumption and exchange, communications, sanitary arrangements, education, mutual protection, defence of the territory, and so on; and, on the other side, for the satisfaction of an ever-increasing number of scientific, artistic, literary and sociable needs. Moreover, such a society would represent nothing immutable. On the contrary—as is seen in organic life at large—harmony would (it is contended) result from an ever-changing adjustment and readjustment of equilibrium between the multitude of forces and influences, and this adjustment would be the easier to obtain as none of the forces would enjoy a special protection from the State.

If, it is contended, society were organized on these principles, man would not be limited in the free exercise of his powers in productive work by a capitalist monopoly, maintained by the State; nor would he be limited in the exercise of his will by a fear of punishment, or by obedience towards individuals or metaphysical entities, which both lead to depression of initiative and servility of mind. He would be guided in his actions by his own understanding, which necessarily would bear the impression of a free action and reaction between his own self and the ethical

conceptions of his surroundings. Man would thus be enabled to obtain the full development of all his faculties, intellectual, artistic and moral, without being hampered by overwork for the monopolists, or by the servility and inertia of mind of the great number. He would thus be able to reach full *individualization*, which is not possible either under the present system of *individualism*, or under any system of State Socialism in the so-called *Volkstaat* (popular State).

The Anarchist writers consider, moreover, that their conception is not a Utopia, constructed on the a priori method, after a few desiderata have been taken as postulates. It is derived, they maintain, from an *analysis of tendencies* that are at work already, even though State Socialism may find a temporary favour with the reformers. The progress of modern technics, which wonderfully simplifies the production of all the necessities of life; the growing spirit of independence, and the rapid spread of free initiative and free understanding in all branches of activity—including those which formerly were considered as the proper attribution of Church and State—are steadily reinforcing the no-government tendency.

Anarchists and the State.—As to economical conceptions, the Anarchists, in common with all Socialists, of whom they constitute the left wing, maintain that the now prevailing system of private ownership in land, and our capitalist production for the sake of profits, represent a monopoly which runs against both the principles of justice and the dictates of utility. They are the main obstacle which prevents the successes of modern technics from being brought into the service of all, so as to produce general well-being. The Anarchists consider the wage-system and capitalist production altogether as an obstacle to progress. But they point out also that the State was, and continues to be, the chief instrument for permitting the few to monopolize the land, and the capitalists to appropriate for themselves a quite disproportionate share of the yearly accumulated surplus of production. Consequently, while combating the present monopolization of land, and capitalism altogether, the anarchists combat with the same energy the State, as the main support of that system, not this or that special form, but the State altogether, whether it be a monarchy or even a republic governed by means of the *referendum*.

The State organization, having always been, both in ancient and modern history (Macedonian empire, Roman empire, modern European States grown up on the ruins of the autonomous cities), the instrument for establishing monopolies in favour of the ruling minorities, cannot be made to work for the destruction of these monopolies. The Anarchists consider, therefore, that to hand over to the State all the main sources of economical life—the land, the mines, the railways, banking, insurance, and so on—as also the management of all the main branches of industry, in addition to all the functions already accumulated in its hands (education, State-supported religions, defence of the territory, etc.), would mean to create a new instrument of tyranny. State capitalism would only increase the powers of bureaucracy and capitalism. True progress lies in the direction of decentralization, both *territorial* and *functional*, in the development of the spirit of local and personal initiative, and of free federation from the simple to the compound, in lieu of the present hierarchy from the centre to the periphery.

In common with most Socialists, the Anarchists recognize that, like all evolution in nature, the slow evolution of society is followed from time to time by periods of accelerated evolution which are called revolutions; and they think that the era of revolutions is not yet closed. Periods of rapid changes will follow the periods of slow evolution, and these periods must be taken advantage of—not for increasing and widening the powers of the State, but for reducing them, through the organization in every township or commune of the local groups of producers and consumers, as also the regional, and eventually the international, federations of these groups.

In virtue of the above principles the anarchists refuse to be party to the present State organization and to support it by infusing fresh blood into it. They do not seek to constitute, and

invite the working men not to constitute, political parties in the parliaments. Accordingly, since the foundation of the first International Working Men's Association in 1864, they have endeavoured to promote their ideas directly amongst the labour organizations and to induce those unions to a direct struggle against capital, distrusting parliamentary legislation.

Historical Development of Anarchism.—The conception of society just sketched, and the tendency which is its dynamic expression, have always existed in mankind, in opposition to the governing hierarchic conception and tendency—now the one and now the other taking the upper hand at different periods of history. To the former tendency we owe the evolution, by the masses themselves, of those institutions—the clan, the village community, the guild, the free mediaeval city—by means of which the masses resisted the encroachments of the conquerors and the power-seeking minorities. The same tendency asserted itself with great energy in the great religious movements of mediaeval times, especially in the early movements of the reform and its forerunners. At the same time it evidently found its expression in the writings of some thinkers, since the times of Lao-tsze, although, owing to its non-scholastic and popular origin, it obviously found less sympathy among the scholars than the opposed tendency.

As has been pointed out by Prof. Adler in his *Geschichte des Sozialismus und Kommunismus*, Aristippus (b. c. 430 B.C.), one of the founders of the Cyrenaic school, already taught that the wise must not give up their liberty to the State, and in reply to a question by Socrates he said that he did not desire to belong either to the governing or the governed class. Such an attitude, however, seems to have been dictated merely by an Epicurean attitude towards the life of the masses.

The best exponent of Anarchist philosophy in ancient Greece was Zeno (342–267 or 270 B.C.), from Crete, the founder of the Stoic philosophy, who distinctly opposed his conception of a free community without government to the State Utopia of Plato. He repudiated the omnipotence of the State, its intervention and regimentation, and proclaimed the sovereignty of the moral law of the individual—remarking already that, while the necessary instinct of self-preservation leads man to egotism, nature has supplied a corrective to it by providing man with another instinct—that of sociability. When men are reasonable enough to follow their natural instincts, they will unite across the frontiers and constitute the *Cosmos*. They will have no need of law-courts or police, will have no temples and no public worship, and use no money—free gifts taking the place of the exchanges. Unfortunately, the writings of Zeno have not reached us and are only known through fragmentary quotations. However, the fact that his very wording is similar to the wording now in use, shows how deeply is laid the tendency of human nature of which he was the mouthpiece.

In mediaeval times we find the same views on the State expressed by the illustrious bishop of Alba, Marco Girolamo Vida, in his first dialogue *De dignitate reipublicae* (Ferd. Cavalli, in *Mem. dell' Istituto Veneto*, xiii.; Dr. E. Nys, *Researches in the History of Economics*). But it is especially in several early Christian movements, beginning with the 9th century in Armenia, and in the preachings of the early Hussites, particularly Chojceki, and the early Anabaptists, especially Hans Denk (cf. Keller, *Ein Apostel der Wiedertäufer*), that one finds the same ideas forcibly expressed—special stress being laid of course on their moral aspects.

Rabelais and Fénelon, in their Utopias, have also expressed similar ideas, and they were also current in the 18th century amongst the French Encyclopaedists, as may be concluded from separate expressions occasionally met with in the writings of Rousseau, from Diderot's *Preface* to the *Voyage* of Bougainville, and so on. However, in all probability, such ideas could not be developed then, owing to the rigorous censorship of the Roman Catholic Church.

These ideas found their expression later during the great French Revolution. While the Jacobins did all in their power to centralize everything in the hands of the Government, it appears now, from recently published documents, that the masses of the people,

in their municipalities and "sections," accomplished a considerable constructive work. They appropriated for themselves the election of the judges, the organization of supplies and equipment for the army, as also for the large cities work for the unemployed, the management of charities, and so on. They even tried to establish a direct correspondence between the 36,000 communes of France through the intermediary of a special board, outside the National Assembly (cf. Sigismund Lacroix, *Actes de la commune de Paris*).

It was W. Godwin, in his *Enquiry concerning Political Justice* (2 vols., 1793), who was first to formulate the political and economical conceptions of anarchism, even though he did not give that name to the ideas developed in his remarkable work. Laws, he wrote, are not a product of the wisdom of our ancestors: they are the product of their passions, their timidity, their jealousies and their ambition. The remedy they offer is worse than the evils they pretend to cure. If and only if all laws and courts were abolished, and the decisions in the arising contests were left to reasonable men chosen for that purpose, real justice would gradually be evolved. As to the State, Godwin frankly claimed its abolition. A society, he wrote, can perfectly well exist without any government: only the communities should be small and perfectly autonomous. Speaking of property, he stated that the rights of every one "to every substance capable of contributing to the benefit of a human being" must be regulated by justice alone: the substance must go "to him who most wants it." His conclusion was communism. Godwin, however, had not the courage to maintain his opinions. He entirely rewrote later on his chapter on property and mitigated his Communist views in the second edition of *Political Justice* (8vo., 1796).

Proudhon Names Anarchy.—Proudhon was the first to use, in 1840 (*Qu'est-ce que la propriété?* first memoir), the name of anarchy with application to the no-government state of society. The name of "anarchists" had been freely applied during the French Revolution by the Girondists to those revolutionaries who did not consider that the task of the Revolution was accomplished with the overthrow of Louis XVI., and insisted upon a series of economical measures being taken (the abolition of feudal rights without redemption, the return to the village communities of the communal lands enclosed since 1669, the limitation of landed property to 120 acres, progressive income-tax, the national organization of exchanges on a just value basis, which already received a beginning of practical realization, and so on).

Now Proudhon advocated a society without government, and used the word anarchy to describe it. Proudhon repudiated, as is known, all schemes of Communism, according to which mankind would be driven into communistic monasteries or barracks, as also all the schemes of State or State-aided Socialism which were advocated by Louis Blanc and the collectivists. When he proclaimed in his first memoir on property that "Property is theft," he meant only property in its present, Roman law sense of "right of use and abuse"; in property rights, on the other hand, understood in the limited sense of *possession*, he saw the best protection against the encroachments of the State. At the same time he did not want violently to dispossess the present owners of land, dwelling-houses, mines, factories, and so on. He preferred to attain the same end by rendering capital incapable of earning interest; and this he proposed to obtain by means of a national bank, based on the mutual confidence of all those who are engaged in production, who would agree to exchange among themselves their products at cost-value, by means of labour cheques representing the hours of labour required to produce every given commodity. Under such a system, which Proudhon described as "Mutuellisme," all the exchanges of services would be strictly equivalent. Besides, such a bank would be enabled to lend money without interest, levying only something like 1%, or even less, for covering the cost of administration. Every one being thus enabled to borrow the money that would be required to buy a house, nobody would agree to pay any more a yearly rent for the use of it. A general "social liquidation" would thus be rendered easy, without violent expropriation. The same applied to mines, railways, factories, and so on.

In a society of this type the State would be useless. The chief relations between citizens would be based on free agreement and regulated by mere account keeping. The contests might be settled by arbitration. A penetrating criticism of the State and all possible forms of government, and a deep insight into all economic problems, were well-known characteristics of Proudhon's work.

It is worth noticing that French mutualism had its precursor in England, in William Thompson, who began by mutualism before he became a Communist, and in his followers John Gray (*A Lecture on Human Happiness*, 1825; *The Social System*, 1831) and J. F. Bray (*Labour's Wrongs and Labour's Remedy*, 1839). It had also its precursor in America. Josiah Warren, who was born in 1798 (cf. W. Bailie, *Josiah Warren, the First American Anarchist*, Boston, 1900), and belonged to Owen's "New Harmony," considered that the failure of this enterprise was chiefly due to the suppression of individuality and the lack of initiative and responsibility. These defects, he taught, were inherent to every scheme based upon authority and the community of goods. He advocated, therefore, complete individual liberty. In 1827 he opened in Cincinnati a little country store which was the first "Equity Store," and which the people called "Time Store," because it was based on labour being exchanged hour for hour in all sorts of produce. "Cost—the limit of price," and consequently "no interest," was the motto of his store, and later on of his "Equity Village," near New York, which was still in existence in 1865. Keith's "House of Equity" at Boston, founded in 1855, is also worthy of notice.

While the economical, and especially the mutual-banking, ideas of Proudhon found supporters and even a practical application in the United States, his political conception of anarchy found but little echo in France, where the Christian Socialism of Lamennais and the Fourierists, and the State Socialism of Louis Blanc and the followers of Saint-Simon, were dominating. These ideas found, however, some temporary support among the left-wing Hegelians in Germany, Moses Hess in 1843, and Karl Grün in 1845, who advocated anarchism. Besides, the authoritarian Communism of Wilhelm Weitling having given origin to opposition amongst the Swiss working men, Wilhelm Marr gave expression to it in the '40s.

On the other side, individualist anarchism found, also in Germany, its fullest expression in Max Stirner (Kaspar Schmidt), whose remarkable works (*Der Einzige und sein Eigentum* and articles contributed to the *Rheinische Zeitung*) remained quite overlooked until they were brought into prominence by John Henry Mackay.

Prof. V. Basch, in a very able introduction to his interesting book, *L'Individualisme anarchiste: Max Stirner* (1904), has shown how the development of the German philosophy from Kant to Hegel, and "the absolute" of Schelling and the *Geist* of Hegel, necessarily provoked, when the anti-Hegelian revolt began, the preaching of the same "absolute" in the camp of the rebels. This was done by Stirner, who advocated, not only a complete revolt against the State and against the servitude which authoritarian Communism would impose upon men, but also the full liberation of the individual from all social and moral bonds—the rehabilitation of the "I," the supremacy of the individual, complete "a-moralism" and the "association of the egotists." The final conclusion of that sort of individual anarchism has been indicated by Prof. Basch. It maintains that the aim of all superior civilization is, not to permit *all* members of the community to develop in a normal way, but to permit certain better endowed individuals "fully to develop," even at the cost of the happiness and the very existence of the mass of mankind. It is thus a return towards the most common individualism, advocated by all the would-be superior minorities, to which indeed man owes in his history precisely the State and the rest, which these individualists combat. Their individualism goes so far as to end in a negation of their own starting-point, to say nothing of the impossibility for the individual to attain a really full development in the conditions of oppression of the masses by the "beautiful aristocracies." His development would remain unilateral. This is why

this direction of thought, notwithstanding its undoubtedly correct and useful advocacy of the full development of each individuality, finds a hearing only in limited artistic and literary circles.

Anarchism in the International Working Men's Association.—A general depression in the propaganda of all factions of Socialism followed, as is known, after the defeat of the uprising of the Paris working men in June 1848 and the fall of the republic. All the Socialist press was gagged during the reaction period, which lasted fully 20 years. Nevertheless, even anarchist thought began to make some progress, namely in the writings of Bellegarrique (*Coeurderoy*) and especially Joseph Déjacque (*Les Lazaréennes, L'Humanisphère*, an anarchist-Communist Utopia, lately discovered and reprinted). The Socialist movement revived only after 1864, when some French working men, all "mutualists," meeting in London during the Universal Exhibition with English followers of Robert Owen, founded the International Working Men's Association. This association developed very rapidly and adopted a policy of direct economical struggle against capitalism, without interfering in the political parliamentary agitation, and this policy was followed until 1871. However, after the Franco-German War, when the International Association was prohibited in France after the uprising of the Commune, the German working men who had received manhood suffrage for elections to the newly constituted imperial parliament, insisted upon modifying the tactics of the International, and began to build up a Social-Democratic political party. This soon led to a division in the Working Men's Association, and the Latin federations, Spanish, Italian, Belgian and Jurassic (France could not be represented), constituted among themselves a federal union which broke entirely with the Marxist general council of the International. Within these federations developed now what may be described as *modern anarchism*. After the names of "federalists" and "anti-authoritarians" had been used for some time by these federations the name of "anarchists," which their adversaries insisted upon applying to them prevailed, and finally it was revindicated.

Bakunin (*q.v.*) soon became the leading spirit among these Latin federations for the development of the principles of anarchism, which he did in a number of writings, pamphlets and letters. He demanded the complete abolition of the State, which—he wrote—is a product of religion, belongs to a lower state of civilization, represents the negation of liberty, and spoils even that which it undertakes to do for the sake of general well-being. The State was an historically necessary evil, but its complete extinction will be, sooner or later, equally necessary. Repudiating all legislation, even when issuing from universal suffrage, Bakunin claimed for each nation, each region and each commune, full autonomy, so long as it is not a menace to its neighbours, and full independence for the individual, adding that one becomes really free only when, and in proportion as, all others are free. Free federations of the communes would constitute free nations.

As to his economical conceptions, Bakunin described himself, in common with his federalist comrades of the International (Cesar De Paepe, James Guillaume, Schwitzguébel), a "collectivist anarchist"—not in the sense of Vidal and Pecqueur in the '40s, or of their modern Social-Democratic followers, but to express a state of things in which all necessities for production are owned in common by the Labour groups and the free communes, while the ways of retribution of Labour, Communist or otherwise, would be settled by each group for itself. Social revolution, the near approach of which was foretold at that time by all Socialists, would be the means of bringing into life the new conditions.

Anarchism and Violence.—The Jurassic, the Spanish, and the Italian federation and sections of the International Working Men's Association, as also the French, the German and the American anarchist groups, were for the next years the chief centres of anarchist thought and propaganda. They refrained from any participation in parliamentary politics, and always kept in close contact with the Labour organizations. However, in the second half of the '80s and the early '90s of the 19th century, when the influence of the anarchists began to be felt in strikes, in May-

day demonstrations, where they promoted the idea of a general strike for an eight-hour day, and in the anti-militarist propaganda in the army, violent prosecutions were directed against them, especially in the Latin countries (including physical torture in the Barcelona castle) and the United States (the execution of five Chicago anarchists in 1887). Against these prosecutions the anarchists retaliated by acts of violence which in their turn were followed by more executions from above, and new acts of revenge from below. This created in the general public the impression that violence is the substance of anarchism, a view repudiated by its supporters, who hold that in reality violence is resorted to by all parties in proportion as their open action is obstructed by repression, and exceptional laws render them outlaws. (Cf., *Anarchism and Outrage*, by C. M. Wilson, and *Report of the Spanish Atrocities Committee*, in "Freedom Pamphlets"; *A Concise History of the Great Trial of the Chicago Anarchists*, by Dyer Lum (N.Y., 1886); *The Chicago Martyrs: Speeches*, etc.)¹

Anarchism continued to develop, partly in the direction of Proudhonian "Mutuellisme," but chiefly as Communist-anarchism, to which a third direction, Christian-anarchism, was added by Leo Tolstoi, and a fourth, which might be ascribed as literary-anarchism, began amongst some prominent modern writers.

The ideas of Proudhon, especially as regards mutual banking, corresponding with those of Josiah Warren, found a considerable following in the United States, creating quite a school, of which the main writers are Stephen Pearl Andrews, William Grene, Lysander Spooner (who began to write in 1850, and whose unfinished work, *Natural Law*, was full of promise) and several others, whose names will be found in Dr. Nettlau's *Bibliographie de l'anarchie*.

¹It is important to remember that the term "anarchist" is inevitably rather loosely used in public in connection with the authors of a certain class of murderous outrages, and that the same looseness of definition often applies to the professions of "anarchism" made by such persons. As stated above, a philosophic anarchist would repudiate the connection. And the general public view, which regards anarchist doctrines indiscriminately, is to that extent a confusion of terms. But the following résumé of the chief modern so-called "anarchist" incidents is appended for convenience in stating the facts under the heading where a reader would expect to find them.

Between 1882 and 1886 in France, Prince Kropotkin, Louise Michel and others were imprisoned. In England, Most, one of the German anarchist leaders, founded *Die Freiheit*, and, for defending in it the assassination of Alexander II. at St. Petersburg, was sentenced to 18 months' imprisonment with hard labour. After this he moved to the United States, and re-established his paper there in New York, in May 1886. During this period there were several anarchist congresses in the United States. In one at Albany, in 1878, the revolutionary element, led by Justus Schwab, broke away from the others; at Allegheny city, in 1879, again there was a rupture between the peaceful and the revolutionary sections. *The Voice of the People* at St. Louis, the *Arbeiter Zeitung* at Chicago, and the *Anarchist* at Boston, were the organs of the revolutionary element. In 1883, at Pittsburgh, a congress of 28 delegates, representing 22 towns, drew up an address to the working men of America. The programme it proposed was as follows:—

First, Destruction of the existing class rule by all means; i.e., energetic, relentless, revolutionary and international action.

Secondly, Establishment of a free society, based upon co-operative organization of production.

Thirdly, Free exchange of equivalent products by and between the productive organizations, without commerce and profit-mongery.

Fourthly, Organization of education on a secular, scientific and equal basis for both sexes.

Fifthly, Equal rights for all, without distinction of sex or race.

Sixthly, Regulation of all public affairs by free contracts between the autonomous (independent) communes and associations, resting on a federalistic basis.

This, together with an appeal to the working men to organize, was published in Chicago, Nov. 1883, by a local committee of four, representing French, Bohemian, German and English sections, the head of the last being August Spies, who was hanged in 1887 for participation in the Haymarket affair in Chicago, May 4, 1886. This affair was the culmination of a series of encounters between the Chicago working men and the police, which had covered several years. The meeting of May 4 was called by Spies and others to protest against the action of the police, by whom several working men had been killed in collisions growing out of the efforts to introduce the eight-hour day. The mayor of the city attended the meeting, but, finding it peaceful, went home. The meeting was subsequently entered by the police and commanded to disperse. A bomb was thrown, several policemen being killed and a number wounded. For this crime eight men were tried in one panel and condemned, seven—Spies, Parsons, Engel, Fischer, Fielden, Schwab

A prominent position among the individualist anarchists in America has been occupied by Benjamin R. Tucker. His journal *Liberty* was started in 1881 and his conceptions are a combination of those of Proudhon with those of Herbert Spencer. Starting from the statement that anarchists are egotists, strictly speaking, and that every group of individuals, be it a secret league of a few persons, or the Congress of the United States, has the right to oppress all mankind, provided it has the power to do so, that equal liberty for all and absolute equality ought to be the law, and "mind every one your own business" is the unique moral law of anarchism, Tucker goes on to prove that a general and thorough application of these principles would be beneficial and would offer no danger, because the powers of every individual would be limited by the exercise of the equal rights of all others. He further indicated (following H. Spencer) the difference which exists between the encroachment on somebody's rights and resistance to such an encroachment, between domination and defence: the former being equally condemnable, whether it be encroachment of a criminal upon an individual, or the encroachment of one upon all others, or of all others upon one; while resistance to encroachment is defensible and necessary. For their self-defence, both the citizen and the group have the right to any violence including capital punishment. Violence is also justified for enforcing the duty of keeping an agreement. Tucker thus follows Spencer, and, like him, opens (in the present writer's opinion) the way for reconstituting under the heading of "defence" all the functions of the State. His criticism of the present State is very searching, and his defence of the rights of the individual very powerful. As regards his economical views B. R. Tucker follows Proudhon.

and Ling—to death, and one—Neebe—to imprisonment for 15 years. The sentences on Fielden and Schwab were commuted by Governor Oglesby to imprisonment for life, on the recommendation of the presiding judge and the prosecuting attorney. Ling committed suicide in gaol, and Spies, Parsons, Engel and Fischer were hanged, Nov. 11, 1887. On June 26, 1893, an unconditional pardon was granted the survivors, Fielden, Schwab and Neebe, by Governor Altgeld. The reasons for the pardon were stated by the governor to be that, on an examination of the records he found that the jury had not been drawn in the usual manner, but by a special bailiff, who made his own selection and had summoned a "prejudiced jury"; that the "State had never discovered who it was that threw the bomb which killed the policemen, and the evidence does not show any connection whatever between the defendants and the man who did throw it," . . . or that this man "ever heard or read a word coming from the defendants, and consequently fails to show that he acted on any advice given by them." Judge Gary, the judge at the trial, published a defence of its procedure in the *Century Magazine*, vol. xliii., p. 803.

A number of outbreaks in later years were attributed to the propaganda of reform by revolution, like those in Spain and France in 1892, in which Ravachol was a prominent figure. In 1893 a bomb was exploded in the French Chamber of Deputies by Vaillant. The spirit of these men is well illustrated by the reply which Vaillant made to the judge who reproached him for endangering the lives of innocent men and women: "There can be no innocent bourgeois." In 1894 there was an explosion in a Parisian café, and another in a theatre at Barcelona. For the latter outrage six men were executed. President Carnot of the French Republic was assassinated by an Italian at Lyons in the same year. The Empress Elizabeth of Austria was assassinated in Sept. 1898. These events, all associated by the public with "anarchism," led to the passage by the United States Congress of a law, in 1894, to keep out foreign anarchists, and to deport any who might be found in the country, and also to the assembling of an international conference in Rome, in 1898, to agree upon some plan for dealing with these revolutionists. It was proposed that their offences should no longer be classed as political, but as common-law crimes, and be made subject to extradition. The suppression of the revolutionary press and the international co-operation of the police were also suggested. The results of the conference were not, however, published; and the question of how to deal with the campaign against society fell for a while into abeyance. The attempt made by the youth Sipido on the (then) prince of Wales at Brussels in 1900 recalled attention to the subject. The acquittal of Sipido, and the failure of the Belgian Government to see that justice was done in an affair of such international importance, excited considerable feeling in England, and was the occasion of a strongly-worded note from the British to the Belgian Government. The murder of King Humbert of Italy in July 1900 renewed the outcry against Italian anarchists. Even greater horror and indignation were excited by the assassination of President McKinley by Czolgosz on Sept. 6, 1901, at Buffalo, U.S.A. and by an attempt made to blow up the young king and queen of Spain on their wedding-day in 1906. (En. E.B.)

The individualist anarchism of the American Proudhonians finds, however, but little sympathy amongst the working masses. Those who profess it—they are chiefly “intellectuals”—soon realize that the *individualization* they so highly praise is not attainable by individual efforts, and either abandon the ranks of the anarchists, and are driven into the liberal individualism of the classical economists, or they retire into a sort of Epicurean a-moralism, or super-man-theory, similar to that of Stirner and Nietzsche. The great bulk of the anarchist working men prefer the anarchist-Communist ideas which have gradually evolved out of the anarchist collectivism of the International Working Men's Association. To this direction belong—to name only the better known exponents of anarchism—Elisée Reclus, Jean Grave, Sébastien Faure, Emile Pouget in France; Enrico Malatesta and Covelli in Italy; R. Mella, A. Lorenzo, and the mostly unknown authors of many excellent manifestos in Spain; John Most amongst the Germans; Spies, Parsons and their followers in the United States, and so on; while Domela Nieuwenhuis occupied an intermediate position in Holland. The chief anarchist papers which have been published since 1880 also belong to that direction; while a number of anarchists of this direction have joined the so-called syndicalist movement—the French name for the non-political Labour movement, devoted to direct struggle with capitalism, which has lately become so prominent in Europe.

Scientific Anarchist-Communism.—As one of the anarchist-Communist direction, the present writer for many years endeavoured to develop the following ideas: to show the intimate, logical connection which exists between the modern philosophy of natural sciences and anarchism; to put anarchism on a scientific basis by the study of the tendencies that are apparent now in society and may indicate its further evolution; and to work out the basis of anarchist ethics. As regards the substance of anarchism itself, it was Kropotkin's aim to prove that Communism—at least partial—has more chances of being established than collectivism, especially in communes taking the lead, and that free, or anarchist-Communism is the only form of Communism that has any chance of being accepted in civilized societies; Communism and anarchy are therefore two terms of evolution which complete each other, the one rendering the other possible and acceptable. He has tried, moreover, to indicate how, during a revolutionary period, a large city—if its inhabitants have accepted the idea—could organize itself on the lines of free Communism; the city guaranteeing to every inhabitant dwelling, food and clothing to an extent corresponding to the comfort now available to the middle classes only, in exchange for a half-day's or a five-hours' work; and how all those things which would be considered as luxuries might be obtained by every one if he joins for the other half of the day all sorts of free associations pursuing all possible aims—educational, literary, scientific, artistic, sports and so on. In order to prove the first of these assertions he has analysed the possibilities of agriculture and industrial work, both being combined with brain work. And in order to elucidate the main factors of human evolution he has analysed the part played in history by the popular constructive agencies of mutual aid and the historical rôle of the State.

Without naming himself an anarchist, Leo Tolstoi, like his predecessors in the popular religious movements of the 15th and 16th centuries, Chojecki, Denk and many others, took the anarchist position as regards the State and property rights, deducing his conclusions from the general spirit of the teachings of the Christ and from the necessary dictates of reason. With all the might of his talent he made (especially in *The Kingdom of God in Yourself*) a powerful criticism of the church, the State and law altogether, and especially of the present property laws. He describes the State as the domination of the wicked ones, supported by brutal force. Robbers, he says, are far less dangerous than a well-organized Government. He makes a searching criticism of the prejudices which are current now concerning the benefits conferred upon men by the church, the State and the existing distribution of property, and from the teachings of the Christ he deduces the rule of non-resistance and the absolute condemnation of all wars. His religious arguments are, however, so

well combined with arguments borrowed from a dispassionate observation of the present evils, that the anarchist portions of his works appeal to the religious and the non-religious reader alike.

It would be impossible to represent here, in a short sketch, the penetration, on the one hand, of anarchist ideas into modern literature, and the influence, on the other hand, which the libertarian ideas of the best contemporary writers have exercised upon the development of anarchism. One ought to consult the ten big volumes of the *Supplément littéraire* to the paper *La révolte* and later the *Temps nouveaux*, which contain reproductions from the works of hundreds of modern authors expressing anarchist ideas, in order to realize how closely anarchism is connected with all the intellectual movement of our own times. J. S. Mill's *Liberty*, Spencer's *Individual versus The State*, Marc Guyau's *Morality without Obligation or Sanction*, and Fouillée's *La morale, l'art et le religion*, the works of Multatuli (E. Douwes Dekker), Richard Wagner's *Art and Revolution*, the works of Nietzsche, Emerson, W. Lloyd Garrison, Thoreau, Alexander Herzen, Edward Carpenter and so on; and in the domain of fiction, the dramas of Ibsen, the poetry of Walt Whitman, Tolstoi's *War and Peace*, Zola's *Paris* and *Le travail*, the works of Merezhkovski and an infinity of works of less known authors,—are full of ideas which show how closely anarchism is interwoven with the work that is going on in modern thought in the same direction of enfranchisement of man from the bonds of the State as well as from those of capitalism. (P. A. K.)

Anarchism Since Kropotkin's Death.—Peter Kropotkin, the author of the foregoing article, died in 1921, at the age of 79. The son of a distinguished Russian family, he renounced the life of the soldier and courtier which opened to him to devote himself to the natural sciences. But the reading of Proudhon turned his mind to social questions, and he became an anarchist of the Proudhonian school. To the propagation of these ideas he devoted the last 60 years of his life; and after the death of Bakunin he was probably the best known anarchist of the last two generations. Imprisoned in both Russia and Switzerland for his activities, he ultimately settled in London, where he was the centre of a distinguished circle of liberal-minded writers and Russian exiles. He wrote prolifically, some of his works, especially *Memoirs of a Revolutionist* (1901), *Mutual Aid* (1904) and *The Conquest of Bread* (1906) exercising considerable influence; while his *History of the French Revolution* is one of the best analyses of its subject written from the angle of extreme hostility to the State. In 1917, the revolution of March permitted him to return to Russia, where he lived until his death. It cannot be said that his last years were happy. He had never sympathised with the Marxist system; and his own passion for anarchist federalism found no comfort in the rigorous and authoritarian centralization of which the Bolsheviks were the sponsors. He was, however, honoured by the new régime as a great figure in the history of Russian revolutionary effort; and his house has been turned into a museum of social history.

It cannot be said, indeed, that anarchism has been other than a declining movement in recent years. It still has its groups of enthusiasts, especially in the Latin countries. Attention was drawn to it in 1909 by the execution, in the face of all the evidence, of the Spanish anarchist Francisco Ferrer, who had mainly been concerned with educational reform movements and was, on all the evidence, a man of the highest nobility of character. A wave of excitement in America in 1919 led to the deportation of certain well-known anarchists to Russia. Among these were Alexander Berkman and Emma Goldman, both of whom were well-known for their propaganda work. They found the new régime intolerable by reason of its sternly authoritarian character, and the constant imprisonment of their anarchist colleagues led them to leave Russia in disgust. Both published angry denunciations of the new system, of which *My Disillusionment in Russia* (1925), by Emma Goldman, is an interesting picture of the reaction of the Bolshevik State upon a mind strongly wedded to freedom. America again became the centre of attention in the civilized world in the summer of 1927 when, after a delay of seven years, two Italian anarchists, Sacco and Vanzetti, were executed

for supposed participation in a crime of violence (see F. Frankfurter, *The Sacco-Vanzetti Case*, 1927). As with Ferrer, 20 years before, the public opinion of the world felt that the execution had taken place less upon the evidence than for the crime of holding extreme opinions.

While anarchism in its classic form has made little headway in recent years, it can, however, claim that its central doctrines have not been without considerable influence. In the form of Proudhonian federalism it has created something like a revival of federalism in France: and the traces of this revival are to be found in the most diverse quarters. Its most usual thesis has been the danger of the centralized State to individual liberty, and under the name of Proudhon, a movement for decentralization has assumed considerable proportions. (See Charles-Brun, *Le Régionalisme* [1911]; *Cahiers du Cercle Proudhon* [1913]; and the prefaces to the new complete edition of Proudhon now in course of publication in Paris.) Another neo-anarchist current of opinion in France derives from Stirner and is ably represented by H. L. Follin, M. L. Lefort and E. Armand. (See especially the latter's *Initiation individualiste-anarchiste* [1923] and, generally, G. Pirou, *Les Doctrines Economiques en France depuis 1870* [1925]).

In England there has been no important anarchist thinker for many years. But, as in France, the reaction against the sovereign State had led to the growth of a political pluralism in which the influence of anarchist theories is apparent. (See, for instance, Bertrand Russell, *Roads to Freedom* [3rd ed., 1920]; H. J. Laski, *A Grammar of Politics* [1925]. G. D. H. Cole, *Social Theory* [2nd ed., 1921]). Anarchist groups, of course, remain but there is no evidence to suggest that they are at all largely influential. (H. J. L.)

ANASTASIUS, the name of four popes. ANASTASIUS I., pope from 399 to 401. He it was who condemned the writings of Origen shortly after their translation into Latin.

ANASTASIUS II., pope from 496 to 498. He lived in the time of the schism of Acacius of Constantinople. He showed some tendency towards conciliation, and thus brought upon himself the lively reproaches of the author of the *Liber pontificalis*. On the strength of this tradition, Dante has placed this pope in hell.

ANASTASIUS III., pope from 911 to 913, was a Roman by birth. Practically nothing is recorded of him, except that he took an active part in determining the ecclesiastical divisions of Germany, his pontificate falling in the period when Rome was in the power of the Roman nobles.

ANASTASIUS IV. was pope from 1153 to 1154. He was a Roman named Conrad, son of Benedictus, and at the time of his election, on July 9 1153, was cardinal bishop of Sabina. He had taken part in the double election of 1130, had been one of the most determined opponents of Anacletus II. and when Innocent II. fled to France had been left behind as his vicar in Italy. During his short pontificate, however, he played the part of peacemaker; he came to terms with the emperor Frederick I. in the vexed question of the appointment to the see of Magdeburg and closed the long quarrel, which had raged through four pontificates, about the appointment of William Fitzherbert (d. 1154)—commonly known as St. William of York—to the see of York, by sending him the pallium in spite of the continued opposition of the powerful Cistercian order. Anastasius died Dec. 3 1154, and was succeeded by Cardinal Nicholas of Albano (Nicholas Breakspear) as Adrian IV.

ANASTASIUS I. (c. 430–518), Roman emperor, was born at Dyrrhachium not later than A.D. 430. At the time of the death of Zeno (491), Anastasius, a palace official (*silentiarius*), bore a very high character, and was raised to the throne of the Roman empire of the East, through the choice of Ariadne, Zeno's widow, who married him shortly after his accession. His reign, though afterwards disturbed by foreign and intestine wars and religious distractions, commenced auspiciously. He gained popular favour by a judicious remission of taxation, and displayed great vigour and energy in administering the affairs of the empire. The principal wars in which Anastasius was engaged were those known as the Isaurian and the Persian wars. The former (492–496) was stirred up by the supporters of Longinus, the brother of Zeno. The victory of Cotyaeum in 493 "broke the back" of the revolt, but a guerilla warfare continued in the Isaurian mountains for some years longer. In the war with Persia (502–505), Theodosiopolis and Amida were captured by the enemy, but the Persian provinces also suffered severely and the Romans recovered Amida. Both adversaries were exhausted when peace was made (506) on the basis of *status quo*.

In 507 Anastasius built the strong fortress of Daras to hold Nisibis in check. The Balkan provinces were devastated by invasions of Slavs and Bulgarians; to protect Constantinople and its vicinity against them he built the "Anastasian Wall" in 512, extending from the Propontis to the Euxine. The emperor was a convinced Monophysite, but his ecclesiastical policy was moder-

ate; he endeavoured to maintain the principle of the *Henotikon* of Zeno and the peace of the church. It was the uncompromising attitude of the orthodox extremists, and the rebellious demonstrations of the Byzantine populace, that drove him in 512 to abandon this policy and adopt a monophysitic programme of religious unity in the East at the cost of Rome's hostility. His consequent unpopularity in the European provinces was utilized by an ambitious man, named Vitalian, to organize a dangerous rebellion, in which he was assisted by a horde of "Huns" (514-515); the rebellion was finally suppressed by a naval victory won by the general Marinus. The financial policy of Anastasius was so prudent and economical that it gained him a reputation for avarice and contributed to his unpopularity. He died July 9 518.

ANASTASIUS II. (d. 721), Roman emperor in the East, whose original name was Artemius, was raised to the throne of Constantinople in A.D. 713, on the deposition of Philippicus, whom he had served in the capacity of secretary. Anastasius sent an army under Leo the Isaurian, afterwards emperor, to defend Syria against the Saracens; adopted wise and resolute measures for the defence of his capital; attempted to reorganize the discipline of the army; and equipped and despatched to Rhodes a formidable naval force. The troops of the Opsician province, resenting the emperor's strict measures, mutinied, slew the admiral, and proclaimed Theodosius emperor. After a six months' siege, Constantinople was taken by Theodosius; and Anastasius, who had fled to Nicaea, was compelled to submit to the new emperor and, retiring to Thessalonica, became a monk (716). In 721 he headed a revolt against Leo, who had succeeded Theodosius; but, though he besieged Constantinople, the enterprise failed and Anastasius, falling into Leo's hands, was put to death by his orders.

ANASTIGMAT, or anastigmatic lens, a photographic lens free from astigmatism (*q.v.*), and which is capable of forming a large sharp image in which a relatively great quantity of light is concentrated. (See **PHOTOGRAPHY: Apparatus**.)

ANASTOMOSIS, the intercommunication between two vessels; a word used chiefly of blood-vessels and other tubes in anatomy for the communication between arteries and veins containing fluid, and also for the communication between the veins or branches of leaves, trees, insect-wings or river-connections, and by analogy in art-design.

ANATASE, one of the three mineral forms of titanium dioxide. It is always found as small, isolated and sharply developed crystals, and like rutile, a more commonly occurring modification of titanium dioxide, it crystallizes in the tetragonal system; but, although the degree of symmetry is the same for both, there is no relation between the interfacial angles of the two minerals, except, of course, in the prism-zone of 45° and 90°. There are also important differences between the physical characters of anatase and rutile; the former is not quite so hard (*H.* = 5½-6) or dense (*sp. gr.* = 3.9); it is optically negative, rutile being positive.

Two types or habits of anatase crystals may be distinguished. The commoner occurs as simple acute double pyramids with an indigo-blue to black colour and steely lustre. Crystals of this kind are abundant at Le Bourg d'Oisans in Dauphiné, where they are associated with rock-crystal, felspar and axinite in crevices in granite and mica-schist. Similar crystals, but of microscopic size, are widely distributed in sedimentary rocks, such as sandstones, clays and slates, from which they may be separated by washing away the lighter constituents of the powdered rock. Crystals of the second type have numerous pyramidal faces developed, and they are usually flatter or sometimes prismatic in habit; the colour is honey-yellow to brown. Such crystals occur attached to the walls of crevices in the gneisses of the Alps, the Binnenthal, Switzerland, being a well-known locality. Another common name for this mineral is octahedrite.

ANATHEMA, any curse, but especially one uttered by the Church for flagrant offences against faith or morals, and accompanied by exclusion from the community. Such exclusion was early practised in Judaism (*cf.* Ezra x. 8) and was developed into a formidable legal instrument by the rabbis (*cf.* "Ban" and "Anathema" in the *Jewish Encyclopedia*). Occasional complaints against the Jewish practice are heard from early Christians (*cf.* John ix. 22, xii. 42, xvi. 2) but similar customs were early adopted by the Church (*cf.* 2 Thess. iii. 14; 1 Cor. v. 5). 1 Cor. xii. 3, xvi. 22; Gal. i. 8, 9 are probably no more than private curses, but Rom. ix. 3 is a significant anticipation of later usage.

Instances of anathema in formulae of condemnation issued by councils are frequent, beginning with the 4th century, *e.g.*, a synod at Elvira (*c.* 300) issued an anathema against those who posted anti-Christian satires in churches and the Council of Nicea (325) anathematized Arianism. The formula, which later became regular and official appears in the canons of a council at Gangra (340?), "If any one (says such and such or behaves so and so), let him be anathema." A distinction between excommunication and anathema was drawn as early as the 6th century, and Pope John VIII. (878) defined "excommunication" as isolation from fellow Christians and "anathema" as separation from the body of Christ, *i.e.*, the Church. The Gratian Decree interprets this definition as implying exclusion from the sacraments. In spite of occasional uncertainty in usage, "anathema" has generally been reserved as a term for the gravest censure pronounced by the Church. In the *Corpus iuris canonici* (Rome, 1917), canon 2,257, it differs from excommunication only in the peculiarly solemn form in which it is pronounced.

The ecclesiastical legislation in canons 2,258-2,267 gives an excellent picture of the far-reaching effects of excommunication in Catholic society, even at the present day. Excommunicated persons are there divided into two classes, *vitandi* who have been publicly and by name denounced by the Apostolic see, and *tolerati* upon whom this sentence has not yet fallen. The society of *vitandi*, even in secular pursuits, is to be avoided except in special circumstances. Excommunicated persons may hear sermons but may not attend mass, and, although a *toleratus* attending mass need not be expelled from the church unless he attempt to take an active part in the service, a *vitandus* should be ejected or the service abandoned, if this can be managed without too great inconvenience. After formal condemnation no excommunicated person may receive sacraments or sacramentalia, or be buried in a Church cemetery, and he may not benefit by the indulgences, suffragia or public prayers of the Church, though private prayers and even masses may be offered on his behalf. In the case of *vitandi*, however, masses may only be said for their conversion. An excommunicated person ordinarily has no right to administer sacraments or sacramentalia, but may do so in the absence of clergy in good standing. Requests for sacraments and sacramentalia, however, should be made by the faithful to *vitandi* only in cases of extreme danger (*in solo mortis periculo*). No excommunicated person may take part in ecclesiastical transactions or procedure, except to appeal from the sentence of excommunication passed upon him, and should enjoy no ecclesiastical benefit or preferments. Ecclesiastical acts (*tam fori externi quam fori interni*) performed by excommunicated persons are, with few exceptions, illegal. For offences by which anathema may be incurred, *cf.* canons 2,314 *seq.* and D. M. Prümmer O. Pr., *Manuale iuris Ecclesiastici* (Friburg in Bregau, 1920), pp. 660 *seq.*

The ritual of anathema, now seldom used, is described in the *Pontificale Romanum* (ed. Joseph Catalan, Rome, 1740, iii. pp. 176 *seq.*). It is performed at the high altar, or in some other public place, by a bishop and 12 priests, all vested and carrying lighted tapers. The bishop recites a solemn formula describing the state of the condemned and the authority by which his excommunication is pronounced. It concludes, "*et (eum) a societate omnium Christianorum separamus, et a liminibus sanctae Matris Ecclesiae in coelo, et in terra excludimus, et excommunicatum, et anathematizatum esse decernimus, et damnatum cum diabolo, et angelis eius, et omnibus reprobis in ignem aeternum indicamus; donec a diaboli laqueis resipiscat, et ad emendationem, et poenitentiam*

redeat, et Ecclesiae Dei, quam laesit, satisfaciatur; tradentes eum satanae in interitum carnis, ut spiritus eius salvus fiat in die iudicii." At this point all cry, "*Fiat, fiat, fiat,*" and dash their lighted candles to the ground. (R. P. C.)

ANATOLI, JACOB (c. 1194–1256), Hebrew translator from the Arabic. He was invited to Naples by Frederick II., and, in association with Michael Scot, made Arabic learning accessible to Western readers. Among his most important services were translations of works by Averroes.

ANATOLIA (Gr. *ἀνατολή*, sunrise, *i.e.*, eastern land), ancient geography, the country east of the Aegean, *i.e.*, Asia Minor. It is now used by the Turks in the form *Anadolu* as the equivalent of the western part of Asia Minor (*q.v.*).

ANATOMY, literally dissection or cutting asunder, a term always used to denote the study of the structure of living things, animal or vegetable. Animal anatomy may include the study of the structure of different animals (*comparative anatomy* or *animal morphology*), or it may be limited to one animal only (*special anatomy*). From a utilitarian point of view the study of Man is the most important division of special anatomy, and this *human anatomy* may be approached from different points of view. From that of the medical man it consists of a knowledge of the exact form, position, size and relationship of the various structures of the human body in health (*descriptive or topographical human anatomy*). From the morphological point of view, human anatomy has for its object the discovery of the causes which have brought about the existing structure of Man, and needs a knowledge of the allied sciences of embryology or ontogeny, phylogeny and histology. Pathological or morbid anatomy is the study of diseased organs, while sections of normal anatomy, applied to various purposes, receive special names such as medical, surgical, gynaecological, artistic and superficial anatomy. The comparison of the anatomy of different races of mankind is part of the science of physical anthropology or anthropological anatomy.

In the present edition of this work the subject of anatomy is treated systematically rather than topographically. Each anatomical article contains first a description of the structures of an organ or system (such as nerves, arteries, heart, etc.), as it is found in Man; and this is followed by an account of the development or embryology and comparative anatomy or morphology, as far as vertebrate animals are concerned.

The following separate anatomical articles will be found under their own headings:—

Alimentary canal.	Nerve.
Arteries.	Nervous system.
Brain.	Olfactory system.
Coelom and serous membranes.	Pancreas.
Connective tissues.	Pharynx.
Diaphragm.	Placenta.
Ductless glands.	Reproductive system.
Ear.	Respiratory system.
Epithelium, Endothelium and glands.	Scalp.
Eye.	Skeleton.
Heart.	Skin and Exoskeleton.
Joints and Ligaments.	Skull.
Liver.	Spinal cord.
Lymphatic system.	Teeth.
Mammary gland.	Tongue.
Mouth and salivary glands.	Urinary system.
Muscular system.	Vascular system.
	Veins.

From the year 1910 onwards the government authorities have not only supervised the administration of the law, but also helped the schools to obtain an adequate supply of unclaimed bodies for their needs. The immediate result has been an extension of sources of supply so as to improve considerably the state of affairs which prevailed previously in Great Britain.

NOMENCLATURE

There is still much confusion in the nomenclature of anatomy. This has arisen from an attempt to revise and improve the

terminology which had previously been in common use. At present either the original or the new "Basle" terminology or a combination of both is employed, a manifest disadvantage. The most important recent advance has been the application of X-rays in the study of macroscopic anatomy, particularly of the living body—an advance which has proved of immense importance in the practice of medicine and surgery. Great improvements have been made in apparatus and technique and particularly in use of materials opaque to the rays for injections.

Osteology.—Advances in connection with the skeleton have been largely concerned with its development, and new views have been expressed as regards the origin, growth and fate of osteoblasts and osteoclasts. Important contributions have been made dealing with the human clavicle, ribs and bones of the face, with sexual differences in the human skull and sexual and racial characters of the human ilium and with the morphology of mammalian teeth and sternum.

Muscular System.—The investigations of Prof. Kulchitsky upon the innervation of muscle fibres, the suggestions of Prof. Hunter that muscle fibres are of two kinds with separate nerve supplies from the central and autonomic systems, and the actual designing of surgical measures for amelioration of muscle spasm based upon these ideas have not yet been sufficiently confirmed.

Nervous System.—C. W. Ariens Kappers has demonstrated that control is exercised upon the grouping of brain cells by forces, probably of a bio-electric character, emanating from the nerve tracts with which these are functionally associated. Attention has been given to the comparison of particular areas of the central nervous system in a series of vertebrates with a view to elucidating the evolutionary significance of these areas in man.

Organs of Sense.—Investigations have been carried out by Karl Pearson, E. Nettleship and C. H. Usher on the subject of albinism in man, showing that eyes, hair and skin may alone show perfect albinism, and that perfect albinism in eyes may be accompanied by imperfect or wholly absent albinism in hair. Other recent publications of importance concern the eye and the ear.

Vascular System.—Recent additions to the knowledge of the vascular system have been chiefly in relation to function, to the blood supply of the valves, the muscular architecture and the development of the human heart, and to the arterial supply of the pons, medulla, and fore-brain, and the development and comparative anatomy of the arteries of the extremities.

Digestive System.—Particular attention has been paid to the teeth, the shape and size of the tonsils at different ages, the minute structure of the oesophagus in mammalia, the form and immediate relations of the abdominal viscera with special reference to their peritoneal attachments, their blood and nerve supply and lymphatic connections.

Respiratory System.—Papers have been written upon the human and comparative anatomy and development of this system with special reference to the lobes of the lungs and the nerve supply of the larynx. Knowledge has been acquired, by means of X-rays, regarding the position of the diaphragm and thoracic viscera.

Genito-Urinary System.—Valuable additions have been made to our knowledge of the appearance of the urethra, bladder and ureter by the cystoscope, and of the kidney by radiography.

See Piersol, *Human anatomy* (6th ed. 1918); Testut, *Traité d'anatomie humaine* (7th ed. 1921–23); Cunningham, *Textbook of anatomy* (5th ed. 1922); Gray, *Anatomy descriptive and applied* (23rd ed. 1926). (F. G. P.; R. W. R.)

SUPERFICIAL AND ARTISTIC

The objects of the study of superficial anatomy are to show, first, the form and proportions of the human body and, second, the surface landmarks which correspond to deeper structures hidden from view. This study blends imperceptibly with others, such as physical anthropology, physiognomy, phrenology and palmistry, but whereas these deal chiefly with variations, superficial anatomy is concerned with the type.

With regard to the proportions of the body the artist and anatomist approach the subject from slightly different points of

A STUDY OF THE HUMAN BODY ACCORDING TO MEASUREMENTS SUGGESTED IN 1890 TO SERVE THE PURPOSE OF ANATOMIST AND ARTIST. Superficial anatomy has a two-fold object: to show the proportions of the human body and to mark the features on the surface which correspond to internal structures. To serve both these purposes the body is divided into $7\frac{1}{2}$ head lengths. Four of these are above the fork and $3\frac{1}{2}$ below. Two heads are allowed for the greatest width of shoulders; $1\frac{1}{2}$ for greatest width of hips, one for narrowest part of waist, and $\frac{3}{4}$ for breadth of head on a level with the eyes.

view. The former, by a process of artistic selection, seeks the ideal and adopts the proportions which give the most pleasing effect, while the latter desires to know only the mean of a large series of measurements.

The scheme which Dr. Paul Richer suggested (*Anatomie artistique*, Paris, 1890), and Professor Arthur Thomson approves (*Anatomy for Art Students*, 1896), is to divide the whole body into head-lengths, of which seven and a half make up the stature. Four of these are above the fork and three and a half below (see figs. 1 and 2). Of the four above, one forms the head and face, the second reaches from the chin to the level of the nipples, the third from the nipples to the navel, and the fourth from there to the fork. By dividing these into half-heads other points can be determined; for instance the middle of the first head-length corresponds to the eyes, the middle of the second to the shoulder, of the fourth to the top of the hip-joint, and of the fifth to the knee-joint.

The elbow-joint, when the arms are by the side, is a little above the lower limit of the third head-length, while the wrist is opposite the very centre of the stature, three head-lengths and three-quarters from the crown or the soles. The tips of the fingers reach a little below the middle of the fifth head-length. (In fig. 1 the fingers are bent.) By making the stature eight head-lengths instead of seven and a half the artistic effect is increased, as it is also by slightly lengthening the legs in proportion to the body. Approximate average breadth measurements are two heads for the greatest width of the shoulders, one and a half for the greatest width of the hips, one for the narrowest part of the waist, and three-quarters for the breadth of the head on a level with the eyes.

The relation of superficial landmarks to deep structures cannot be treated here in full detail, but the chief points may be indicated. Certain parts of the head may easily be felt through the skin. If the finger is run along the upper margin of the orbit, the notch for the supraorbital nerve may usually be felt at the junction of the inner and middle thirds. At the outer end of the margin is its junction with the malar bone, and this easily felt point is known as the external angular process. The junction of the frontal and nasal bones at the root of the nose is the nasion, while at the back of the skull the external occipital protuberance or inion is felt and marks the position of the torcular Herophili, where the venous sinuses meet. The zygoma may be felt running back from the malar bone to just in front of the ear, and two fingers' breadth above the middle of it marks the pterion, a very

important point in the localization of intracranial structures. It corresponds to the anterior branch of the middle meningeal artery, to the Sylvian point where the three limbs of the fissure of Sylvius diverge, to the middle cerebral artery, the central lobe of the brain or island of Reil, and the anterior part of the corpus striatum. The fissure of Sylvius can be marked out by drawing a line from the external angular process back through the Sylvian point to the lower part of the parietal eminence. The position of the sulcus of Rolando is important because of the numerous cortical centres which lie close to it. It may be mapped out by taking the superior Rolandic point, $\frac{1}{2}$ in. behind the bisection of a line drawn from the nasion to the inion over the vault of the skull, and joining that to the inferior Rolandic point, which is just above the line of the fissure of Sylvius and 1 in. behind the Sylvian point. The external parieto-occipital fissure, which forms the boundary between the parietal and occipital lobes of the brain, is situated practically at the lambda, which is a hand's breadth ($2\frac{3}{4}$ in.) above the inion. The lateral sinus can be mapped out by joining the inion to the asterion, a point two-thirds of the distance from the lambda to the tip of the mastoid process; thence the sinus curves downward and forward toward the tip of the mastoid process. A point 1 in. horizontally backward from the top of the external auditory meatus will always strike it.

The Face.—On the front of the face a line drawn down from the supraorbital notch between the bicuspid teeth to the side of the chin will cut the exit of the second division of the fifth nerve from the infraorbital foramen, a quarter of an inch below the infraorbital margin, and also the exit of the third division of the fifth at the mental foramen, midway between the upper and lower margins of the body of the jaw. The angle of the mouth at rest usually corresponds to the interval between the bicuspid teeth. The skin of the eyelids is very thin, and is separated from the subjacent fibrous tarsal plates by the orbicularis palpebrarum muscle. On everting the lids the delicate conjunctival membrane is seen, and between this and the tarsal plates lie the meibomian glands, which can be faintly seen as yellowish streaks. From the free edges of the eyelids come the eyelashes, between which many large sweat-glands open, and when one of these is inflamed it causes a "stye." Internally the two eyelids form a little recess called the internal canthus, occupied by a small red eminence, the caruncula lachrymalis, just external to which a small vertical fold of conjunctiva may often be seen, called the plica semilunaris, representing the third eyelid of birds and many mammals. By gently drawing down the lower eyelid the lower punctum may

be seen close to the caruncula; it is the pinhole opening into the lower of the two canaliculi which carry away the tears to the lachrymal sac and duct. On the side of the face the facial artery may be felt pulsating about an inch in front of the angle of the jaw; it runs a tortuous course to near the angle of the mouth, the angle of the nose and the inner angle of the eye; in the greater part of its course its vein lies some distance behind it. The parotid gland lies between the ramus of the jaw and the mastoid process; anteriorly it overlaps the masseter to form the *socia parotidis*, and just below this its duct, the duct of Stensen, runs forward to pierce the buccinator and open into the mouth opposite the second upper molar tooth. The line of this duct may be marked out by joining the lower margin of the tragus to a point midway between the lower limit of the nose and the mouth. The facial or seventh nerve emerges from the skull at the stylo-mastoid foramen just in front of the root of the mastoid process; in the parotid gland it forms a network called the *pes anserinus*, after which it divides into six branches which radiate over the face to supply the muscles of expression.

The Neck.—In the middle line below the chin can be felt the body of the hyoid bone, just below which is the prominence of the thyroid cartilage called “Adam’s apple,” better marked in men than in women. Still lower the cricoid cartilage is easily felt, while between this and the suprasternal notch the trachea and isthmus of the thyroid gland may be made out. At the side the outline of the sterno-mastoid muscle is the most striking mark; it divides the anterior triangle of the neck from the posterior. The upper part of the former contains the submaxillary gland, which lies just below the posterior half of the body of the jaw. The line of the common and the external carotid arteries may be marked by joining the sterno-clavicular articulation to the angle of the jaw. The eleventh or spinal accessory nerve corresponds to a line drawn from a point midway between the angle of the jaw and the mastoid process to the middle of the posterior border of the sterno-mastoid muscle and thence across the posterior triangle to the deep surface of the trapezius. The external jugular vein can usually be seen through the skin; it runs in a line drawn from the angle of the jaw to the middle of the clavicle, and close to it are some small lymphatic glands. The anterior jugular vein is smaller, and runs down about half an inch from the middle line of the neck. The clavicle or collar-bone forms the lower limit of the neck, and laterally the outward slope of the neck to the shoulder is caused by the trapezius muscle.

The Chest.—It is important to realize that the shape of the chest does not correspond to that of the bony thorax which encloses the heart and lungs; all the breadth of the shoulders is due to the shoulder girdle, and contains the axilla and the head of the humerus. In the middle line the suprasternal notch is seen above, while about three fingers’ breadth below it a transverse ridge can be felt, which is known as Ludovic’s angle and marks the junction between the manubrium and gladiolus of the sternum. Level with this line the second ribs join the sternum, and when these are found the lower ribs may be easily counted in a moderately thin subject. At the lower part of the sternum, where the seventh or last true ribs join it, the ensiform cartilage begins, and over this there is often a depression popularly known as the pit of the stomach. The nipple in the male is situated in front of the fourth rib or a little below; vertically it lies a little external to a line drawn down from the middle of the clavicle; in the female it is not so constant. A little below it the lower limit of the great pectoral muscle is seen running upward and outward to the axilla; in the female this is obscured by the breast, which extends from the second to the sixth rib vertically and from the edge of the sternum to the mid-axillary line laterally. The female nipple is surrounded for half an inch by a more or less pigmented disc, the areola. The apex of a normal heart is in the fifth left intercostal space, three and a half inches from the mid-line.

The Abdomen.—In the mid-line a slight furrow extends from the ensiform cartilage above to the symphysis pubis below; this marks the *linea alba* in the abdominal wall, and about its

middle point is the umbilicus or navel. On each side of it the broad recti muscles can be seen in muscular people. The outline of these muscles is interrupted by three or more transverse depressions indicating the *lineae transversae* in the recti; there is usually one about the ensiform cartilage, one at the umbilicus, and one between; sometimes a fourth is present below the umbilicus. The upper lateral limit of the abdomen is the sub-costal margin formed by the cartilages of the false ribs (8, 9, 10) joining one another; the lower lateral limit is the anterior part of the crest of the ilium and Poupart’s ligament running from the anterior superior spine of the ilium to the spine of the pubis (*see* fig. 1, δ); these lower limits are marked by definite grooves. Just above the pubic spine is the external abdominal ring, an opening in the muscular wall of the abdomen for the spermatic cord to emerge in the male. The most modern method of marking out the abdominal contents is to draw three horizontal and two vertical lines; the highest of the former is the transpyloric line of C. Addison (fig. 1, T.P.), which is situated half-way between the suprasternal notch and the top of the symphysis pubis; it often cuts the pyloric opening of the stomach an inch to the right of the mid-line. The hilum of each kidney is a little below it, while its left end approximately touches the lower limit of the spleen. It corresponds to the first lumbar vertebra behind. The second line is the subcostal (fig. 1, S.C.), drawn from the lowest point of the subcostal arch (tenth rib); it corresponds to the upper part of the third lumbar vertebra, and is an inch or so above the umbilicus; it indicates roughly the transverse colon, the lower ends of the kidneys, and the upper limit of the transverse (3rd) part of the duodenum. The third line is called the intertubercular (fig. 1, I.T.), and runs across between the two rough tubercles, which can be felt on the outer lip of the crest of the ilium about two and a half inches from the anterior superior spine. This line corresponds to the body of the fifth lumbar vertebra, and passes through or just above the ileo-caecal valve where the small intestine joins the large. The two vertical or mid-Poupart lines are drawn from the point midway between the anterior superior spine and the pubic symphysis on each side vertically upward to the costal margin. The right one is the most valuable, as the ileo-caecal valve is situated where it cuts the intertubercular line, while the orifice of the vermiform appendix is an inch lower down. At its upper part it meets the transpyloric line at the lower margin of the ribs, usually the ninth, and here the gall-bladder is situated. The left mid-Poupart line corresponds in its upper three-quarters to the inner edge of the descending colon. The right subcostal margin corresponds to the lower limit of the liver, while the right nipple is about half an inch above the upper limit of this viscus.

The Back.—There is a well-marked furrow stretching down the middle line of the back from the external occipital protuberance to the cleft of the buttocks. In this the spinous processes of the vertebrae can be felt, especially if the model bend forward. The cervical spines are difficult to feel, except the seventh and sometimes the second, and although the former is called the vertebra prominens, its spine is less easily felt than is that of the first thoracic. In practice it is not very easy to identify any one spine with certainty: one method is to start from the prominent first thoracic and to count down; another is to join the lower angles of the two scapulae (fig. 2, γ) when the arms are hanging down, and to take the spine through which the line passes as the seventh.

The spinal furrow is caused by the prominence of the erector spinae muscles on each side; these become less well marked as they run upward. The outlines of the scapulae can be well seen; they cover the ribs from the second to the seventh inclusive. The scapular spine is quite subcutaneous, and can be followed upward and outward from the level of the third thoracic spine to the acromion, and so to the outer end of the clavicle. On the lower margin of the acromion is a little tubercle known as the metacromial process or acromial angle, which is very useful for taking measurements from. The tip of the twelfth rib may usually be felt about two inches above the middle of the iliac crest, but this rib is very variable in length. The highest point

of the iliac crest corresponds to the fourth lumbar spine, while the posterior superior iliac spine is on a level with the second sacral vertebra. This posterior superior spine is not easily felt, owing to the ligaments attached to it, but there is usually a little dimple in the skin over it (fig. 2, β). By drawing horizontal lines through the 1st, 3rd and 5th lumbar spines, the transpyloric, subcostal and intertubercular lines or planes may be reproduced behind and the same viscera localized.

The Arm.—Running downward and outward from the inner half of the clavicle, where that bone is convex forward, is the clavicular part of the pectoralis major, while from the outer third of the bone, where it is concave forward, is the clavicular part of the deltoid; between these two muscles is an elongated triangular gap with its base at the clavicle, and here the skin is somewhat depressed, while the cephalic vein sinks between the two muscles to join the axillary vein. The tip of the coracoid process is situated just under cover of the inner edge of the deltoid, one inch below the junction between the outer and middle thirds of the clavicle. The deltoid muscle (fig. 1, β) forms the prominence of the shoulder, and its convex outline is due to the presence of the head of the humerus deep to it; when this is dislocated the shoulder becomes flattened. The pectoralis major forms the anterior fold of the axilla or armpit, the posterior being formed by the latissimus dorsi and teres major muscles. The skin of the floor of this space is covered with hair in the adult, and contains many large sweat-glands. The axillary vessels and brachial plexus of nerves lie in the outer wall, while on the inner wall are the serrations of the serratus magnus muscle, the outlines of some of which are seen on the side of the thorax, through the skin, when the arm is raised (fig. 1, α). Below the edge of the pectoralis major, the swelling of the biceps (fig. 1, γ) begins to be visible, and this can easily be traced into its tendon of insertion, which reaches below the level of the elbow-joint. On each side of the biceps is the external and internal bicipital furrow, in the latter of which the brachial artery may be felt and compressed. The median nerve is here in close relation to the artery. At the bend of the elbow the two condyles of the humerus may be felt; the inner one projects beneath the skin, but the outer one is obscured by the rounded outline of the brachio-radialis muscle. The superficial veins at the bend of the elbow are very conspicuous; they vary a good deal, but the typical arrangement is an M, of which the radial and ulnar veins form the uprights, while the outer oblique bar is the median cephalic and the inner oblique the median basilic vein. At the divergence of these two the median vein comes up from the front of the forearm, while the two vertical limbs are continued up the arm as the cephalic and basilic, the former on the outer side, the latter on the inner. On the back of the arm the three heads of the triceps are distinguishable, the external forming a marked oblique swelling when the forearm is forcibly extended and internally rotated (fig. 2, δ). In the upper part of the front of the forearm the antecubital fossa or triangle is seen; its outer boundary is the brachio-radialis, its inner the pronator radii teres, and where these two join below is the apex. In this space are three vertical structures—externally the tendon of the biceps, just internal to this the brachial artery, and still more internally the median nerve. Coming from the inner side of the biceps tendon the semi-lunar fascia may be felt; it passes deep to the median basilic vein and superficial to the brachial artery, and in former days was a valuable protection to the artery when unskilful operators were bleeding from the median basilic vein. About the middle of the forearm the fleshy parts of the superficial flexor muscles cease, and only the tendons remain, so that the limb narrows rapidly. In front of the wrist there is a superficial plexus of veins, while deeper down two tendons can usually be made to start up if the wrist be forcibly flexed; the outer of these is the flexor carpi radialis, which is the physician's guide to the radial artery where the pulse is felt. If the finger is slipped to the outer side of this tendon, the artery, which here is very superficial, can be felt beating. The inner of the two tendons is the palmaris longus, though it is not always present. On cutting down between these two the median nerve is reached.

The wrist-joint may be marked out by feeling the styloid process of the radius on the outer side, and the styloid process of the ulna on the inner side behind, and joining these two by a line convex upward. The superficial appearance of the palm of the hand is described in the article on PALMISTRY; with regard to anatomical landmarks the superficial palmar arterial arch is situated in the line of the abducted thumb, while the deep arch is an inch nearer the wrist. The digital nerves correspond to lines drawn from the clefts of the fingers toward the wrist. On the back of the forearm the olecranon process of the ulna is quite subcutaneous, and during extension of the elbow is in a line with the two condyles, while between it and the inner condyle lies the ulnar nerve, here known popularly as the "funny-bone." From the olecranon process the finger may be run down the posterior border of the ulna, which is subcutaneous as far as the styloid process at the lower end. When the thumb is extended, two tendons stand out very prominently; the outer of these is the tendon of the extensor brevis, the inner of the extensor longus pollicis. Situated deeply in the space is the radial artery, covered by the radial vein. On the dorsum of the hand there is a plexus of veins, and deep to these the tendons of the extensor longus digitorum stand out when the wrist and fingers are extended.

The Leg.—Just below Poupart's ligament (fig. 1, δ), a triangular depression with its apex downward may be seen in muscular subjects; it corresponds to Scarpa's triangle, and its inner border is the tendon of the adductor longus, which is easily felt if the model forcibly adducts the thigh. In this triangle the superficial inguinal glands may be made out. The head of the femur lies just below the centre of Poupart's ligament. The sartorius muscle forms the outer boundary of the triangle, and may be traced from the anterior superior spine obliquely downward and inward, across the front of the thigh, to the inner side of the knee. The two vasti muscles are well marked, the internal being the lower and forming with the sartorius the rounded bulging above the inner side of the knee. The internal saphenous vein runs superficially up the inner side of the thigh from behind the internal condyle of the femur to the saphenous opening in the deep fascia, the top of which is an inch horizontally outward from the spine of the pubis. On the other side of the thigh a groove runs down which corresponds to the ilio-tibial band, a thickening of the fascia lata or deep fascia; the lower end of this leads to the head of the fibula. On the front of the thigh, below the sartorius, the rectus muscle makes a prominence which leads down to the patella, the outlines of which bone are very evident (fig. 1, ϵ). The only part of the femur besides the great trochanter which is superficial is the lower end, and this forms the two condyles for articulation with the tibia. If the posterior part of the inner condyle be joined to the mid-point between the anterior superior spine and the symphysis pubis, when the thigh is externally rotated, the line will correspond in its upper two-thirds to that of the common and superficial femoral arteries, the former occupying the upper inch and a half. The common femoral vein lies just internal to its artery, while the anterior crural nerve is a quarter of an inch external to the latter. The rounded mass of the buttock is formed by the gluteus maximus muscle covered by fat; the lower horizontal boundary is called the fold of the nates, and does not correspond exactly to the lower edge of the muscle. At the side of the buttock is a depression (fig. 2, ϵ) where the great trochanter of the femur can be felt; a line, named after Nelaton, drawn from the anterior superior spine to the tuberosity of the ischium, passes through the top of this. On the back of the thigh the hamstrings form a distinct swelling; below the middle these separate to enclose the diamond-shaped popliteal space (fig. 2, ζ), the outer hamstrings or biceps being specially evident, while, on the inner side, the tendons of the semi-tendinosus and semi-membranosus can be distinguished.

On the front of the leg, below the knee, the ligamentum patellae is evident, leading down from the patella (fig. 1, ϵ) to the tubercle of the tibia. From this point downward the anterior border of the tibia or shin is subcutaneous, as is also the internal surface

of the tibia. External to the shin is the fleshy mass made by the tibialis anticus and extensor longus digitorum muscles. At the inner side of the ankle the internal malleolus is subcutaneous, while on the outer side the tip of the external malleolus is rather lower and farther back. Both this malleolus and the lower quarter of the shaft of the fibula are subcutaneous, and this area, if traced upward, is continuous with a furrow on the outer side of the leg which separates the anterior tibial from the peroneal groups of muscles, and eventually leads to the subcutaneous head of the fibula. At the back of the leg the two heads of the gastrocnemius form the calf, the inner one (fig. 2, η) being larger than the outer. Between the two, in the mid-line of the calf, the external saphenous vein and nerve lie, while lower down they pass behind the external malleolus to the outer side of the foot. The internal saphenous vein and nerve lie just behind the internal border of the tibia, and below pass in front of the internal malleolus. At the level of the ankle-joint the tibialis posticus and flexor longus digitorum tendons lie just behind the internal malleolus, while the peroneus longus and brevis are behind the external. Running down to the heel is the tendo Achillis with the plantaris on its inner side. On the dorsum of the foot the musculo-cutaneous nerve may be seen through the skin in thin people when the toes are depressed; it runs from the anterior peroneal furrow, already described, to all the toes, except the cleft between the two inner ones. There is also a venous arch to be seen, the two extremities of which pass respectively into the external and internal saphenous veins. The long axis of the great toe, even in races unaccustomed to boots, runs forward and outward, away from the mid-line between the two feet, so that perfectly straight inner sides to boots are not really anatomical. The second toe in classical statues is often longer than the first, but this is seldom seen in Englishmen. On the outer side of the sole the skin is often in contact with the ground all along, but on the inner side the arch is more marked, and, except in flat-footed people, there is an area in which the sole does not touch the ground at all.

RADIOGRAPHY

The Skull.—An instructive radiogram of the skull is obtained by placing the tube generating the rays on one side of the head and by laying the photographic plate flat against the other. Fig. 1 on plate shows a lateral view of the head resting upon the upper part of the spinal column. A good view is obtained of the extent of the cavity which contains the brain. The orbital and nasal chambers with their accessory air sinuses (antrum of Highmore and sphenoidal air sinus) are well seen. Particularly there is noticeable, immediately behind the sphenoidal sinus, the saddle-shaped sella turcica for the lodgment of the pituitary gland.

Shoulder.—A front view of the shoulder and neighbouring part of the chest when the arm hangs by the side of the body, discloses the relative position of the bones of that region. The ribs pursue an obliquely downward course and their movements in life are well seen.

The clavicle passes outwards and slightly upwards toward the acromion process of the scapula, with it to form a bony arch overhanging the shoulder joint and thus helping to prevent upward displacement of the humerus at that joint. The body of the scapula rests on the ribs thickening at its axillary border and upper and outer angle where it expands to form the glenoid fossa for reception of the head of the humerus. The coracoid process which is swung by fibrous tissue to the clavicle in the recent state is very evident.

The ball and socket character of the shoulder-joint is so arranged as to allow of extensive movement of the arm at the joint, the socket (glenoid cavity) being small as compared with the large articulating surface of the ball. The upper extremity of the

humerus with its articular surface and tuberosities are well seen.

Elbow.—A good picture of this region is obtained by taking a radiograph from its inner side with the elbow-joint slightly bent and the forearm in such a position that the palm of the hand is directed toward the median plane of the body. The lower end of the humerus shows the internal condyle with a ridge running upward and a groove behind for the passage of the ulnar nerve from the arm into the forearm. The upper end of the ulna shows the deep concavity by which it articulates with the pulley-shaped surface of the humerus and its helmet-shaped upward extension (olecranon process) for the attachment of the triceps muscle. The head of the radius supported upon its conical neck articulates with the humerus above and the ulna at the side. The whole picture emphasizes the hinge-like character of the elbow-joint and the pivot character of the joint between the bones of the forearm at the elbow.

Wrist and Hand.—Fig. 5 on plate shows the lower part of the forearm and hand viewed from the palmar aspect. The radius and ulna, the carpal, metacarpal and phalangeal bones form distinct shadows. The outline of the wrist-joint shows that the hand is supported mainly by the expanded lower end of the radius, the head of the ulna being separated from the carpus by an interval which in the recent state is filled up by a fibrocartilaginous pad.

The outlines of all the eight bones of the carpus can clearly be made out forming a group consisting of two rows of bones with an ω -shaped joint between them. The os magnum is the largest bone of the group and lies with its long axis in line with the middle finger, the semi-lunar and the radius. Its rounded head fits into a cup formed by the scaphoid and semi-lunar; its body is flanked by the trapezoid and unciform, and its base supports the third and to a lesser degree the second and fourth metacarpal bones. The pisiform is rather indefinitely seen immediately below the ulna and in front of the cuneiform. The trapezium partially hides the trapezoid.

The four inner metacarpal bones lie close to one another, while the first or that of the thumb is separated from the second by a wide interval. A small sesamoid bone is seen lying upon the inside of its head.

The phalanges of the fingers and thumb are shown very distinctly, and the ball and socket character of the metacarpophalangeal and the hinge-like nature of the inter-phalangeal joints are also manifest.

Pelvis and Hip-joint.—The architecture of the bony framework of the pelvis which transmits the weight of the trunk and upper extremities allowing at the same time room for viscera is well seen in fig. 6 on plate.

The relation of the wedge-shaped sacrum with its coccygeal appendage to the rest of the body girdle is apparent. The sacrum is seen to be interlocked between the ilia of the innominate bones, so as to form with them an arch transmitting the superincumbent weight either to the lower extremity in the erect position or to the ischial tuberosity in the sitting position. The tendency towards the spreading of the arch is prevented by the front portions of the pelvic girdle acting as tie beams, and there are three "buffers" which break shocks, one at the symphysis pubis in the middle of the front part of the girdle, and the other two at joints between the sacrum and ilia. The foramina for the exit of nerves from the spinal cord to supply the lower extremities and soft parts of pelvis are apparent. The general character of the female as compared with the male pelvis is well exemplified in fig. 6; e.g., the widely spreading ilia, the great width of cavity below the ilia and the wide sub-pubic angle.

To get a good radiogram of the region of the hip-joint is a somewhat difficult matter. One taken from the front shows the thigh occupying its position in the erect posture, revealing the socket or acetabulum, the head of the femur with its pit for the round ligament, the oblique neck, and the upper part of the shaft with the great and small trochanters. The arrangement of the cancellous bone tissue is such as to bear the superincumbent weight in the best possible way.

Knee.—A good general idea of the region is obtained by taking

BY COURTESY OF DR. LEVACK, DR. SPRIGGS, AND DR. SALMOND

PARTS OF THE HUMAN ANATOMY PHOTOGRAPHED BY RADIOGRAPHY

1. Lateral view of the head of a living person
2. Radiogram showing a side view of the knee
3. Normal stomach after ingestion of a barium meal
4. The bone structure of the ankle and foot
5. Radiogram showing the thumb as opposable to the rest of the hand
6. The bone structure of the pelvis and hip-joint

a radiogram from the side (fig. 2 on plate). It shows the lower part of the femur with its condyles, upper part of the tibia with its spine, tuberosities and tubercle, and the upper part of the fibula with its head.

There is seen to be but little interlocking between the femur, tibia and patella, which enter into the formation of the knee-joint. The tibia articulates by a relatively small surface with the relatively large articular surface of the femur, the joint so formed being an example of a hinge joint with the pin of the hinge a movable one. The spine of the tibia is seen projecting upward between the condyles of the femur acting like the flange of a wheel and so helping to prevent lateral displacement of the tibia from the femur at the joint. The knee-cap, to which are attached the great extensor muscles of the leg, moves upward and downward on the femur only. The fibula is seen articulating with the tibia, the joint surface being oblique in direction in order to break shocks between the two bones.

Ankle and Foot.—In fig. 4 on plate a view of the skeleton of the lower part of the leg and of the foot is given from the inside. The tibia and fibula of the leg, and the tarsal and metatarsal and some of the phalangeal bones are shown.

The tibia articulates with the astragalus at the ankle joint, and on close inspection the relative positions of the malleoli of both the tibia and fibula to the astragalus can be made out, the bones of the leg and the astragalus forming a hinge joint. The tip of the outer malleolus formed by the fibula reaches to a lower level than the tip of the inner malleolus, which belongs to the tibia.

The antero-posterior and to a less extent the transverse arch of the foot are shown, the pillars of the former consisting of the great tuberosity of the os calcis behind and of the heads of the metatarsal bones in front. The astragalus forms the keystone of the arch, and transmits the weight of the body from the tibia to the astragalus and os calcis behind, and to the scaphoid, cuboid, cuneiform and metatarsal bones in front. The spicules of the cancellous tissue in these bones are arranged so as to bear the weight of the body transmitted through them. The so-called tunnel of the tarsus and the mediotarsal joint across the foot between the astragalus and os calcis behind and the scaphoid and cuboid in front are very apparent, showing at the same time that the articulation between the os calcis and cuboid forms a separate joint. The front of the middle cuneiform is indicated by a narrow vertical shadow situated a little behind the shadow indicating the anterior border of the internal cuneiform.

The radiogram illustrates vividly the essential difference between the hand and the foot, in that the big toe is seen to be closely applied to the second toe and not opposable to the rest of the foot as the thumb is to the rest of the hand.

Ossification.—Ossification begins in each bone of the skeleton at one or more spots called "primary centres of ossification." Each appears before birth and by their spreading they form the main part of the bone. After birth "secondary centres of ossification" begin to show themselves independently of the main mass, form what are known as "epiphyses" and join it at various periods after birth to make the adult bone. Radiography, when applied to the living body, affords information as to the forms, times of first appearance and times of junction of the epiphyses with the main parts of bones to which they belong. It has shown that there is very great variability in the times, appearance and fusion of epiphyses in different individuals.

Thorax and its Contents.—Apart from revealing the skeleton of the thorax, radiography permits inspection of the position and contour of the heart and great vessels, the lungs and mediastinum.

Abdomen and its Contents.—Subsequent to the introduction of matter opaque to X-rays such as barium or bismuth salts into certain organs, radiography has played an important part in elucidating the anatomy of the alimentary canal and urinary tract.

Fig. 3 on plate shows a normal stomach and first part of the duodenum immediately after the ingestion of a barium meal. The clear area at the upper part indicates the air-containing portion of the cavity in the neighbourhood of the entrance of the oesophagus.

The writer of this article is indebted to Dr. Levack, Radiologist,

Royal Infirmary, Aberdeen; Dr. Spriggs, Duff House, Ruthin Castle, North Wales; and Dr. Salmond, Radiologist, University College hospital, London, for the radiograms that are reproduced in Figs. 1 to 6.

ANAU, site of an abandoned settlement 20m. E.S.E. from Ashkhabad in the Turkmenistan S.S.R. There are indications of four different cultures, the two earlier from a *kurgan* (mound) about a mile west of the ruins and $\frac{1}{2}$ mile south of the Transcaspian railway and the two later from a *kurgan* about 1 mile further south. The earliest inhabitants were grain cultivators and had handmade pottery geometrically decorated. Pumpelly, calculating from loess deposits, dated the cultures 8,000-6,000 B.C., but 3,900-3,300 B.C. seems more probable.

ANAXAGORAS, Greek philosopher, born probably about 500 B.C. (Apollodorus *ap. Diog. Laert.* ii. 7) at Clazomenae in Asia Minor. He went to Athens, which was rapidly becoming the headquarters of Greek culture (c. 464-462 B.C.). There he is said to have remained for 30 years. Pericles learned to love and admire him and the poet Euripides derived from him an enthusiasm for science and humanity. Some authorities assert that even Socrates was among his disciples. His influence was due partly to his astronomical and mathematical eminence, but still more to the ascetic dignity of his nature and his superiority to ordinary weaknesses.

It was he who brought philosophy and the spirit of scientific inquiry from Ionia to Athens. His observations of the celestial bodies led him to form new theories of the universal order, and brought him into collision with the popular faith. He attempted to give a scientific account of eclipses, meteors, rainbows and the sun, which he described as a mass of blazing metal, larger than the Peloponnesus; the heavenly bodies, he said, were masses of stone torn from the earth and ignited by rapid rotation. The polytheism of the time could not tolerate such explanation, and the enemies of Pericles used the superstitions of their countrymen as a means of attacking him in the person of his friend.

Anaxagoras was arrested on a charge of contravening the established dogmas of religion (some say the charge was one of Medism) and it required all the eloquence of Pericles to secure his acquittal. Even so he was forced to retire from Athens to Lampsacus (434-433 B.C.), where he died about 428 B.C. Anaxagoras holds that all things have existed in a sort of way from the beginning. But originally they existed in infinitesimally small fragments of themselves, endless in number and inextricably combined throughout the universe.

All things existed in this mass, but in an indistinguishable form. There were the seeds (*σπέρματα*) of corn and flesh and gold in the mixture; but these parts, of like nature with their wholes (the *δμοιομερῆ* of Aristotle), had to be eliminated from the complex mass before they could receive a definite name and character.

The existing species of things having thus been transferred, with all their specialties, to the prehistoric stage, they were multiplied endlessly in number by reducing their size through continued subdivision; at the same time each thing is so connected with every other that the keenest analysis can never completely sever them. The work of arrangement, the segregation of like from unlike and the summation of the *ἁπλομερῆ* ("simple substances") into totals of the same name, was the work of Mind or Reason. This peculiar thing called Mind (*νοῦς*), was no less illimitable than the chaotic mass, but, unlike the Intelligence of Heraclitus (*q.v.*), it stood pure and independent (*μόνος ἐφ' ἑωυτοῦ*), a thing of finer texture, and everywhere the same.

This agent, possessed of all knowledge and power, is especially seen ruling in all the forms of life. Its first appearance, and the only manifestation of it which Anaxagoras describes, is Motion. It originated a rotatory movement in the mass which, arising at one point, gradually extended till it gave distinctness to the aggregates of like parts. But even after it has done its best, the original intermixture is not wholly overcome. No one thing in the world is ever abruptly separated from the rest. The name given to it signifies merely that in that congeries of fragments the particular "seed" is preponderant. Every *a* of this present universe is only *a* by a majority, and is also in lesser number *b*, *c*, *d*. It is noteworthy that Aristotle accuses Anaxagoras of failing to differentiate between *νοῦς* and *Ψυχή* while Socrates (Plato, *Phaedo*, 98 B) objects that his *νοῦς* is merely a *deus ex machina* to which he refuses to attribute design and knowledge.

Anaxagoras gave some account of the process from original chaos to present arrangements. First came the division into cold mist and warm ether. With increasing cold, the former gave rise to water, earth and stones. The seeds of life in the air were carried down with the rains and produced vegetation. Animals, including man, sprang from the warm and moist clay. We seem to see things coming into being and passing from it; but reflection tells us that decrease and growth only mean a new aggregation (*σύνκρισις*) and disruption (*διάκρισις*). Thus Anaxagoras distrusted the senses, and preferred the conclusions of reflection. Accordingly, he maintained that there must be blackness as well as whiteness in snow; how otherwise could it be turned into dark water?

With Anaxagoras speculation passed from the colonies of Greece to settle at Athens. His theory of minute constituents and mechanical processes paved the way for the atomic theory. On the other hand the conception of reason in the world passed from him to Aristotle, to whom it seemed the dawn of sober thought after a night of disordered dreams. From Aristotle it descended to his commentators, and under the influence of Averroes became the engrossing topic of speculation.

BIBLIOGRAPHY.—The fragments of Anaxagoras have been collected by E. Schaubach (Leipzig, 1827), and W. Schorn (Bonn, 1829); see also F. W. A. Mullach, *Fragmenta Philos. Graec.*, i. 243–252; A. Fairbanks, *The First Philosophers of Greece* (1898). For criticism see T. Gomperz, *Greek Thinkers* (Eng. trans., L. Magnus, 1901), bk. ii. chap. 4; E. ANAXIMANDER, the second of the physical philosophers of Ionia, was a citizen of Miletus and a companion or pupil of Thales. The computations of Apollodorus have fixed his birth in 611, and his death shortly after 547 B.C. He taught the obliquity of the ecliptic, is said to have introduced into Greece the gnomon (for determining the solstices) and the sundial, and to have made the first map. But his reputation is due mainly to his work on nature. From the few fragments which remain we learn that the first principle was a boundless mass (*ἄπειρον*), eternal and indestructible, from which all beings came, by the separating out of

opposites, and to which they will return. From this primal body there sprung a central fiery mass enclosing the rings of sun, moon and stars, with the earth in the middle, cylindrical in shape, and held in place "because of its equal distance from everything." Living creatures arose from moisture evaporating in the sun. Man was supposed by Anaximander to have sprung from some other species of animals, probably aquatic, "for had he been originally as he is now he would never have survived."

See Histories of the Ionian School by Ritten, Mallet; Schleiermacher, "Dissert. sur la philosophie d'Anaximandre," in the *Mémoires de l'Acad. des sciences de Berlin* (1815); J. Burnet, *Early Greek Philosophy* (1892); A. W. Benn, *Greek Philosophers* (1883 foll.); A. Fairbanks, *First Philosophers of Greece* (1898); Ritter and Preller, *Historia Phil.* 88 17–22; Mullach, *Fragmenta Phil. Graec.* i. 237–240; Burnet, *Early Greek Philosophy* (1908), ch. i. § 2; Diels, *Fragmente der Vorsokratiker*, vol. i. (1912); and IONIAN SCHOOL OF PHILOSOPHY.

ANAXIMENES, of Lampsacus (c. 380–320 B.C.), Greek rhetorician and historian, was a favourite of Alexander the Great, whom he accompanied in his Persian campaigns. He wrote histories of Greece and of Philip, and an epic on Alexander (fragments in Müller, *Scriptores Rerum Alexandri Magni*). As a rhetorician, he was a determined opponent of Isocrates and his school. The *Rhetorica ad Alexandrum*, usually included among the works of Aristotle, is now generally admitted to be by Anaximenes, although some consider it a much later production (edition by Spengel, 1847).

See P. Wendland, *Anax. von Lampsakos* (1905); see also RHETORIC.

ANAXIMENES, of Miletus, Greek philosopher in the latter half of the 6th century, said to have been the "associate of Anaximander." He held that air is the primary substance; it expands with heat or contracts with cold, and by these changes of density is the source of all that exists. The earth is a flat disc floating in air, with the heavenly bodies rotating round it.

Graec.* i. 241–243; J. Burnet, *Early Greek Philosophy*, ch. i. § 3 (1920); also IONIAN SCHOOL OF PHILOSOPHY; EVOLUTION.

ANAZARBUS, an ancient Cilician city, situated in the Aleian plain about 10 m. W. of the main stream of the Pyramus (Jihun) and near its tributary, the Sempas Su. A lofty isolated ridge formed its acropolis. Under the early Roman empire the place was known as *Caesarea*, and was the metropolis of Cilicia Secunda. Rebuilt by the emperor Justin after an earthquake, it became *Justinopolis* (A.D. 525); but the old native name persisted, and when Thoros I., king of Lesser Armenia, made it his capital early in the 12th century, it was known as Anazarva. Its great natural strength and situation not far from the mouth of the Sis pass, and near the great road which debouched from the Cilician gates, made Anazarbus play a considerable part in the struggles between the Byzantine empire and the early Muslim invaders. It had been rebuilt by Harun al-Rashid in A.D. 796, refortified at great expense by Saif addaula, the Hamdanid (10th century), and Saiked, and ruined by the crusaders.

The present wall of the lower city is of late construction, probably Armenian. It encloses a mass of ruins conspicuous in which are a fine triumphal arch, the colonnades of two streets, a gymnasium, etc. A stadium and a theatre lie outside.

ANBAR (originally Firuz Shapur or Perisopora), a ruined town on the left bank of the Euphrates in 33° 30' N., 43° 50' E., below the modern Ramadi (*q.v.*) and between 40 and 50 m. from Baghdad. The town lies just south of the Sakhlawiye canal, the most northerly of the canals which link with the Tigris. It was originally founded in A.D. 350 by Shapur II., was destroyed by Julian, but rebuilt and became a Christian and Jewish centre; and it is said to have had 90,000 Jews at the time of its capture by Ali in A.D. 657. It was the original capital of the Abbasid caliphate until the founding of Baghdad. It continued to be an important centre and even had a Christian governor under Caliph Mu'tadid.

ANCACHS, a department of central Peru, between the Pacific and the valley of the Marañon, with the department of La Libertad on the north, and that of Lima on the south (area 14,705 sq.m., estimated population 428,703, doubtless somewhat below the actual figure). Lying partly on the arid coast, partly in the

high cordilleras, it has a variety of climates and products. Two lofty chains parallel with the coast, Cordillera Negra on the west, Cordillera Blanca on the east, include some of the highest peaks in Peru (Huascarán). They hem in a wide, fertile valley, that of the Sante or Huaráz, the largest coast stream. It is unique among the rivers of Peru as it rises east of the continental divide, flows from south to north in a longitudinal valley, cuts the western cordillera in a narrow gorge and empties into the Pacific. The climate of this valley is in general mild, with moderate rainfall. From south to north the principal crops are barley, potatoes, wheat and maize. Cattle and sheep are also raised. A series of towns, Recuay, Huaráz, Yungai, Caráz, Huailás, follow the stream. On the eastern slopes of the Cordillera Blanca tributaries of the Marañon flow east, while from western slopes of the Cordillera Negra, short streams cross the desert to the Pacific. In their valleys sugar-cane, cotton, rice and tropical fruits are grown. The chief ports, Chimbote, Samanco and Casma, each with a few hundred inhabitants, are situated on protected though shallow harbours. A road from Casma over the Cordillera Negra (pass 14,000ft.) is the chief means of access to the capital, Huaráz (*q.v.*). The highly mineralized mountains are at present but little exploited; the largest establishment is in Ticapampa, at the south. The principal deposits are silver and lead, placer gold (Chuquicara), copper (Huari), tungsten (Pallasca), coal (Ancos and Caráz). Living conditions are still primitive owing to lack of transportation facilities. There are 426m. of finished roads in the department, and construction is actively going forward. One narrow-gauge State railway runs from Chimbote up the Santa valley to Huallaca, 85m. distant. Many interesting pre-Columbian remains can be seen both on the coast and in the mountains.

ANCAEUS, in Greek legend, son of Zeus or Poseidon, king of the Leleges of Samos. In the Argonautic expedition, after the death of Tiphys, helmsman of the "Argo," he took his place. It is said that, while planting a vineyard, he was told by a soothsayer that he would never drink of its wine. As soon as the grapes were ripe, he squeezed the juice into a cup, and, raising it to his lips, mocked the seer, who retorted with the words, Πολλὰ μεταξύ πέλει κύλικος καὶ χεῖλεος ἀκροῦ ("there is many a slip between the cup and the lip"). At that moment it was announced that a wild boar was ravaging the land. Ancaeus set down the cup, leaving the wine untasted, hurried out, and was killed by the boar.

ANCELOT, JACQUES ARSENE FRANÇOIS POLYCARPE (1794-1854), French dramatist and *littérateur*, was born at Havre, Feb. 9 1794, and died in Paris Sept. 7 1854. His best-known plays were *Louis IX.* (1819), *Le Maire du palais* (1825) and *Maria Padilla* (1838).

ANCESTOR-WORSHIP. In savage and barbarian belief, as in civilized sentiment, death does not make a person cease to belong to his social unit (family, clan, tribe, village, nation). Hence, since the living and the dead of any given community are as much one as any other two classes thereof—for instance, the older and the younger men—we might expect to find the dead treated much as are the older living members of the community, especially the dead who died at a ripe age, or at least after bearing or begetting offspring. For those who die immature are often treated as of less account, or as in some way different, while a common confusion of thought leads to conceiving all persons who died a long time ago as old. Now the aged are regarded in three different ways: (a) with contempt, owing to their physical weakness; hence they are not infrequently killed as *bouches inutiles*; (b) with fear, owing to their supposed magical powers; (c) with respect, as repositories of the traditional wisdom of their people, and often as more or less definite rulers; *e.g.*, the elders of an Australian tribe. We find the dead regarded more or less in all these ways by various peoples, but the matter is complicated by the following considerations: (1) All dead, as such, are terrible, because death is contagious, and where one person has died (especially by violence) more deaths are apt to follow. (2) The dead cannot fend for themselves, cannot hunt or look for vegetable food, etc., but as they are beloved or venerated members of the community they should be provided with necessities, as a sick

brother or a wise but feeble old medicine-man, tribal counsellor, or witch might be. (3) The dead or some of the dead (*e.g.*, chiefs or sorcerers) become more powerful than ever by reason of their death; they are now spirits able to help or harm, and should therefore be propitiated. This often blends with (1). (4) The dead, or some of them, return and are re-born into the community. (5) The older dead, if not quite forgotten, tend to become vague, idealized figures, often passing into gods.

Mere neglect of the dead, as of no account, is very rare; awe or fear, with or without affection as for kinsmen or fathers and mothers, is the prevailing attitude. The ideas given under (2) lead rather to tendance of the dead (offerings of food, etc., at their graves, soul feasts, destruction of all or some of the dead man's property to be of use to him in the other world) than to actual worship. All the ideas numbered (1), (3), and (5) may and do lead to worship of one sort or another; (4) is somewhat more complicated in its results.

Clearly, if the dead can be re-born (*see* RE-INCARNATION), it is desirable to make sure that only the "good" dead shall thus re-enter the community. For persons unlucky, inefficient, scorners of law and justice, the survivors have no use whatever and do not want them back. Moreover, of the good dead, *i.e.*, those powerful, magically or materially efficient, observers of custom, some are so important that they will not condescend to become babies. Hence we get, among other things, a difference in funeral ceremonies; ordinary decent people are buried in one way, great chiefs in another; criminals, women dead in childbirth, men killed by wild beasts, etc., perhaps in a third (*see* DEAD, DISPOSAL OF THE). So far, no worship is necessarily implied, but we get prayers addressed to those of the dead who are expected to return. For instance, the Edo imagine that their normal dead will go to their heaven, *elimi*, stay there for a time, during which they can send blessings to the survivors, and finally return. "My father," one of their prayers runs, "tell Osa (God) to give you things when you come back." This touches ancestor-worship, at least at one point; for a time the dead man is a worshipful ghost whose favours may be sought; he can also confer a last favour by providing well for his own life on earth before he returns (*Journ. Roy. Anth. Inst.*, 1920, p. 380 ff.). But it is not yet complete and typical.

Another practice very like ancestor-worship at first sight is the worship of what may be called the life-stream. The object of this cult is not any man, living or dead, but the power which enables the community to continue in existence by natural increase—a power which may be embodied for the time being in the head of the family or clan and worshipped by him and his dependents. The Roman *genius* (*q.v.*) in its earliest form is an example of this.

TYPES OF ANCESTOR-WORSHIP

But ancestor-worship pure and simple is directed towards ancestors possessing venerable powers of one sort or another, coupled with either a kindly interest in their descendants or at least the ability to do them harm if they neglect them. It may be of several kinds, according to the beliefs of the people practising it.

Communal Worship.—(I.) The dead may be worshipped *en masse* by the family, clan, or other community to which they belong; *i.e.*, of which, while alive, they were really or supposedly members. The best known instances of this come from ancient Italy. The cult of the *manes* (*q.v.*) at Rome was not a worship of any individuals; that of the *di parentes* or *parentum* was the cult or tendance of all the dead of a particular line. This fits the belief in the *genius* quite logically. The really worshipful thing, the life-force, is gone from the dead man and there is little or nothing left to give him individuality or importance. For the most part, the cult consisted in the provision of food, either solemnly given to the ghosts, as at the Lemuralia, etc., or in the form of a communal banquet, in which presumably the ghosts had their share. But that these ghosts were not without power, at least collectively, is shown to some extent by the story that once, when the rites of the *parentalia* in February were neglected, the result was a plague which lasted until they were restored (*cf.* [1], above; Ovid. *Fast.*, ii. 545-554), but more decisively (for

such tales may be the result of Ovid's or another's imagination) by the dates of the festivals, in early spring and early summer, just when the ghosts who live in the ground can help or harm the crops, and by the inclusion of the *di manes* in the formula of *devotio* (Livy, viii. 9, 6), from which it appears that they were strong at least to curse.

Individual Worship.—(II.) On the whole, however, the worship of individual ancestors is more common. This may, after a fashion, be combined with (I.), for a large number, or even the entire series of ancestors, so far as they are remembered, may receive collective cult. This is often the case in Africa. For instance, at the *adae* or ceremony of worship of ancestral spirits carried out by a queen-mother among the Ashanti, Capt. Rattray heard of seven stools, each belonging to one of the dead queen-mothers, having each an offering placed upon it (Rattray, *Ashanti*, p. 104). But these same people have many prayers in which the ancestral spirits (*samanfo*) are addressed collectively. Such things, however, are to be expected among a people believing in more than one supernatural being of any kind, for it is not always thought necessary to address each object of cult in a separate prayer or ceremony.

Grades of Ancestors.—(III.) For the reason given in (3) above, not all ancestors are equally worshipful. It is plain that since a commoner was of little importance in life he is not a very powerful ghost; consequently, while such minor spirits are tended only by their immediate relatives, or perhaps not at all, the ghosts of great men are singled out for much more elaborate cult by the whole community. Thus the spirit of a Samoan chief is "supposed to be nearer than the spirits of common people," and is consulted "on all important occasions" (Rev. G. Brown, *Melanesians and Polynesians*, p. 209). His magical power, of course, was far greater than that of a commoner in his lifetime; but the ghosts even of commoners count for something; they "are consulted also" by their own descendants (*ibid.*). This is much the same idea as that underlying Greek hero-cult. But it is not merely prominence, even magical prominence, in life which brings about promotion after death to the rank of a worshipful ancestor. Seniority also has much to do with it; we often find that the founder of a family continues to be worshipped by that family throughout an indefinite number of generations; this worship is, of course, not affected by the circumstance that the founder in question never had any real existence. We find this at all manner of stages in culture, from the reverence paid by Australian blacks of to-day to their mythical *alcheringa* (see FAMILY; ARUNTA), to the practice of the civilized Greeks, who not only described themselves as "sons or descendants of such a one" (e.g., Iamidae, descended from the legendary seer, Iamus, son of Apollo) but also definitely worshipped their founder, honouring him above all the intervening ancestors. On the other hand, the older ghosts may be forgotten in time—the number of generations in a pedigree that can be remembered, while often considerable, is not without limits—and in that case the once worshipful ancestor fades vaguely into the mass of ghosts or disappears altogether, unless he becomes a god. A ghost who has shown himself formidable, or a person whose death was in some way strange, may quite well enjoy high rank among the venerated ancestors, even if he has been of little account in life. Again, the ancestor most worshipped may be the last person of importance to die: "their father whom they knew is the head by whom they begin and end in their prayer, for they know him best," says one of Callaway's Zulu witnesses (*Religious System of the Amazulu*, p. 144). It by no means always follows that the character of the ghost, venerated or not, will be identical with that of the living person: "perhaps he, too, who was good becomes bad when he is dead; and he who was bad, when he is dead, is good and becomes a good Itongo" (*ibid.*, p. 151).

Ancestors as Gods.—(IV.) Finally, some one ancestor may so combine in his own person all the worshipful qualities a good ancestral ghost should have, or show such pre-eminence in some one quality, that he is no longer treated as a ghost, however venerable, but receives the full honours due to a god. Among many peoples it is a matter of considerable doubt, both to themselves,

when they give any thought to the matter, and to European investigators, whether they have any gods; i.e., any beings supernatural and non-human from the start, or only more or less worshipful ghosts adored by a greater or smaller portion of the community. This confusion is illustrated by the classical case of Asclepius, who was worshipped in many parts of Greece as a god, but is also several times spoken of as a hero; i.e., a worshipful ghost, with a clan, the *Asclepiadae*, called after him. It was an artificial clan, a guild of physicians; but this makes no difference. It is quite possible that a real man, renowned in his lifetime for his medical skill, lies behind the cult and myth of the god (see L. R. Farnell, *Greek Hero-Cults*, p. 234 ff.). Practically any work on the Pacific cultures will give instances of the same confusion.

If we ask why ancestors are worshipped, apart from the desire to propitiate them and prevent them doing harm because they are neglected and angry, the answer varies almost indefinitely. Ghosts are often thought of as living in or just outside the house; thus the Zulu *amatongo* frequently enter houses in the form of snakes (Callaway, *op. cit.*, p. 126 ff.). A Greek house had frequently a house-hero (*ἡρώς οἰκουρὸς*), originally no doubt the spirit of some ancestor, whose influence, if he was properly looked after by the inhabitants, was good. In particular, he might intervene to beget a much desired child on the housewife, taking the form of her husband for the purpose (see HERODOTUS, vi. 69; the hero Astrabacus, one of the ancient royal house, comes from his shrine in the form of King Ariston of Sparta and becomes by the latter's wife the father of Demaratos). Offspring is indeed a boon regularly expected from ancestors, who, even if they are not supposed themselves to return and be re-incarnated, naturally are interested in the continuance of the line which tends or worships them. For a like reason they are expected to protect it in various ways, averting illness, giving warning and advice in dreams, and so forth. Again, as ghosts often are supposed to live in the ground, the ancestors are commonly worshipped in hopes of getting good crops. Thus in Malabar, at the feast of Vishnu, (the beginning of the agricultural year) the celebrant prays: "May the gods on high, and the deceased ancestors, bless the seed. . . . May they also vouchsafe us a good crop." (C. Karunakara Menon in E. Thurston's *Omens and Superstitions of Southern India*, p. 291). As they are thus associated with gods, they are often called upon to intercede with gods (see Sir J. G. Frazer, *Worship of Nature*, vol. i., p. 159); for they often live in the sky or some other abode of the deity or deities. But the above are only typical examples; there is almost nothing which an ancestral spirit may not be called upon to grant or to avert. Their relation to the gods is usually indeed that of inferior to superior; but they are commonly supposed to enjoy a larger share of divine favour than the dwellers on earth, if only because they live closer to the deities and so can act as "friends at court" for their worshippers. Usually, however, their ritual differs in kind as well as in degree from that of great gods, regularly preserving something of the methods supposed to be efficacious for securing the repose of a ghost.

DIFFUSION OF ANCESTOR-WORSHIP

The custom is found among peoples very widely distributed, and in all grades of culture. It is not, however, so nearly universal as either the fear of ghosts or the cult of supernatural beings of some kind. Thus, the ancestors of totemic tribes are themselves totems; but it can hardly be said that the totem is worshipped; i.e., made the object of prayer and other forms of cult. It is not a god, but rather a respected kinsman. The totemic ceremonies of North America, for instance, consist largely in mimetic dances in which the celebrants are assimilated to the totem, rather than in performances intended to please it, or as requests to it to send some blessing. Totemism may here and there develop into worship, but can hardly be said to be worship (see TOTEMISM and Sir J. G. Frazer, *Totemism and Exogamy*, ii. p. 18). Again, merely to care for the comfort of the dead ancestors is not necessarily to worship them; the Roman *parentalia* were quite as much tendance as worship proper. But examples of true ancestor-worship are very numerous, when all deductions have been made. Instances

have been quoted from Africa, Asia and the Pacific islands, in all three of which it flourishes. Of civilized races, the Greeks, Romans and Vedic Indians all had it in a more or less developed form, and it has been claimed as a common Indo-Germanic heritage. This is possible but not certain. Of existing cultured peoples, the Chinese and Japanese are the best-known examples (*see* CONFUCIUS; TAOISM). Where it has completely disappeared the reason is normally the adoption of a monotheistic religion, as Christianity, Judaism, or Islam; hence it is no longer found in Europe. It is not necessarily inconsistent with the existence of a very high form of religious or ethical belief, such for example as Confucianism.

BIBLIOGRAPHY.—No complete modern work dealing specifically with this subject exists. For the civilized races, *see* the literature of the articles GREEK RELIGION; ROMAN RELIGION, etc. Standard older works are Sir H. Maine, *Ancient Law*; Fustel de Coulanges, *La cité antique*. For uncivilized peoples, besides the works quoted in the text, *see* especially Ploss-Renz, *Das Kind*, chap. xlviii. (Leipzig, 1912); J. G. Frazer, *The Belief in Immortality* (1913-1924); L. Lévy-Bruhl, *La Mentalité primitive* (1922). (H. J. R.)

ANCHISES, in Greek legend, son of Capys and Themis, grandson (according to Hyginus, son) of Assaracus, of the junior branch of the royal family of Troy, king of Dardanus on Mt. Ida. Here Aphrodite met him and, enamoured of his beauty, bore him Aeneas. For revealing the name of the child's mother, he was killed or struck blind by lightning (Hyginus, *Fab.*, 94). In more recent legend, adopted by Virgil in the *Aeneid*, he was conveyed out of Troy on the shoulders of his son Aeneas (q.v.) and died in Sicily.

ANCHOR. The most ancient anchors consisted of large stones, baskets full of stones, sacks filled with sand, or logs of wood loaded with lead. Of this kind were the anchors of the ancient Greeks; they held the vessel merely by their weight and by the friction along the bottom. When iron was introduced for the construction of anchors, an improvement was made by form-

miralty pattern anchor, which is still used for light work and in boats, is shown in fig. 1. The parts of the anchor are known as: the shank, the ring, the stock, the crown, the arms, the flukes, the pea or bill, and the gravity band. It will be noted that, by removing the keep pin, the anchor can be "unstocked" for stow-

FROM THE "MANUAL OF SEAMANSHIP," BY PERMISSION OF THE CONTROLLER OF H.M. STATIONERY OFFICE

FIG. 2.—FRONT VIEW OF MARTIN'S CLOSE STOWING ANCHOR

ing. The anchor must be "stocked" before letting go, to ensure that one of the flukes takes the ground.

Later came the self-canting and close-stowing Martin anchor, which, passing through successive improvements, became the improved Martin anchor (fig. 2).

In this pattern the arms are in one plane and can turn through an angle of about 40° either side of the stock. Projections on the

arms known as tripping palms (K) cause the arms to rotate, if the anchor is dragged along the bottom, when the flukes will catch in the ground. It is superior to the Admiralty pattern because both flukes are holding the ship instead of only one. It is also much easier to stow.

To stow a stocked anchor on the anchor-bed it is hove up close to the forefoot, and by means of a ground chain (secured to a balancing or gravity band on the anchor), which is joined to a catting chain rove through a cat davit, the anchor is hove up horizontally and placed on its bed, where it is secured by chains passing over a rod fitted with a lever for "letting go."

Stockless anchors have now replaced the older pattern almost entirely for bow, sheet, and sometimes stern anchors. The latest type of this anchor is shown in fig. 3.

In 1903 they were adopted generally for the British Navy, after extensive anchor trials begun in 1885. Their advantages are: handiness combined with a saving of time and labour; absence of davits, anchor-beds and other gear, with a resulting reduction in

ing them with teeth or "flukes" to fasten themselves to the bottom.

Until the beginning of the 19th century anchors were of imperfect manufacture, the means of effecting good and efficient welding being absent and the iron poor, whilst the arms, being straight, generally parted at the crown when weighing from good holding-ground. A clerk in the Plymouth yard, named Pering, in the early part of that century (1813) introduced curved arms; and after 1852 the Admiralty anchor, under the direction of the Board, was supplied to H.M. ships. The present form of Ad-

FIG. 3.—FRONT AND SIDE ELEVATION OF A STOCKLESS ANCHOR

The word "anchor" is derived from the Greek ἄγκυρα which Vossius considers is from ἄγκη, a crook or hook.

ANCHORITE, a hermit or recluse, one who has withdrawn himself from the world, usually for religious reasons. The name is specially used for the hermits of the East in the early Christian era.

ANCHOVY (*Engraulis encrasicolus*), a fish of the herring family distinguished by its deeply cleft mouth, the angle of the

which annually migrate from the Zuider Zee to the Atlantic in autumn, returning in the following spring. The shallow and landlocked waters of the Zuider Zee become raised to a higher temperature in summer than any part of the sea about the British coasts, and therefore anchovies are able to spawn in these waters. Spawning takes place in June and July. The eggs are buoyant and transparent but peculiar in having an elongated, sausage-like shape. They resemble those of the sprat and pilchard in having a segmented yolk and no oil globule. The larva hatches two or three days after fertilization and is very minute and

FIG. 4.—METHOD OF STOWING THE STOCKLESS ANCHOR ON SHIPBOARD

transparent. The so-called "Norwegian anchovies" imported into England in little wooden kegs are sprats pickled in brine with bay-leaves and pepper.

ANCHOVY EGGS, a savoury dish. To make it, beat three eggs slightly and stir them over a fire, together with $\frac{3}{4}$ oz. of butter, a tablespoonful of milk, $\frac{1}{2}$ -teaspoonful of anchovy essence, pepper, salt, capers or other seasoning. When the mixture thickens, pour

gape being behind the eyes. The pointed snout extends beyond the lower jaw. The fish resembles a sprat in having a forked tail and a single dorsal fin, but the body is round and slender. The maximum length is $8\frac{1}{2}$ in. Anchovies are abundant in the Mediterranean, and are regularly caught on the coasts of Sicily, Italy, France and Spain. The range of the species also extends along the Atlantic coast of Europe to south Norway. In summer it enters the Zuider Zee in such numbers as to give rise to a regular and valuable fishery. It is also taken in the estuary of the Scheldt. The anchovies found at the western end of the English Channel in November and December are probably those

it on to hot buttered toast and decorate it with capers and anchovies laid crosswise.

ANCHOVY PEAR (*Grias cauliflora*), the common name for a tall slender tree cultivated in the West Indies and belonging to the family Lecythidaceae. The russet-brown fruit, which is about 3 in. long, is eaten pickled.

ANCHOVY TOAST, a pleasant savoury dish, best made as follows: Chop coarsely six boned anchovies, fry in butter with a finely chopped small onion and the yolk of an egg. Add, if desired, chopped parsley and cayenne pepper. When the mixture thickens, pour on to hot buttered toast.

ANCIEN RÉGIME, THE, a French phrase commonly used to denote the social and political system established in France under the old monarchy. (See FRANCE: History.)

ANCIENT or ANTIEN, old or in olden times. "Ancient history" is distinguished from mediaeval and modern, generally as meaning before the fall of the Western Roman empire. "The Ancient of days" is a Biblical phrase for God. In the London Inns of Court the senior barristers used to be called "ancients." From the 16th to the 18th century the word was also used, by confusion with "ensign," i.e., standard-bearer, for that military title (cf. Shakespeare's "ancient Pistol"). (See also ANCIENT LIGHTS; DEMESNE.)

ANCIENT LIGHTS, a phrase in English law for a negative easement (*q.v.*) consisting in the right to prevent the owner or occupier of an adjoining tenement from building or placing on his own land anything which has the effect of illegally obstructing or obscuring the light of the dominant tenement. At common law a person who opens a window in his house has a natural right to receive the flow of light that passes through it. But his neighbour is not debarred thereby from building on his own land even though the effect of his action is to obstruct the flow of light thus obtained. Where, however, a window has been opened for so long a time as to constitute immemorial usage in law, the light becomes an "ancient light," which the law protects from disturbance. The Prescription Act, 1832, created a statutory prescription for light. It provided (s. 3) that "when the access and use of light to and from" (any building) "shall have been actually enjoyed therewith for the full period of 20 years without interruption, the right thereto shall be deemed absolute and indefeasible, any local usage or custom to the contrary notwithstanding, unless it shall appear that the same was enjoyed by some consent or agreement, expressly made or given for that purpose by deed or writing." Since under the statute an "interruption" in order to prevent the right accruing must be one of at least a year, the period of prescription is really only 19 years. But the right given by the statute is inchoate, unless and until the dominant owner's claim is decided by the court, and the period of prescription must be the years immediately preceding the action raising the question. But in the meantime, however long the enjoyment may have been, the dominant owner's right is just the same, and the origin of his right is just the same as if the act had never been passed. These principles were laid down in 1904 by the House of Lords in the leading case of *Colls v. Home and Colonial Stores, Ltd.* (1904, A. C. 179). There has been much difference of judicial opinion as to what constitutes an actionable interference with "ancient lights." On the one hand, the test has been prescribed that if an angle of 45°—uninterrupted sky light—was left, the easement was not interfered with, and, while this is not a rule of law, it is a good rough working criterion. However, it has now been decided by the House of Lords in *Colls v. Home and Colonial Stores (supra)* that there must be a privation of light substantial enough to render the occupation of the house or building uncomfortable according to the ordinary notions of mankind and (in the case of business premises) to prevent the plaintiff from carrying on his business as beneficially as before. See also *Kine v. Jolly* (1905, 1 Ch. 480). The ordinary remedy for a disturbance of "ancient lights" is an injunction. Under the act commonly called Lord Cairns' Act, 1858, however, the court has power to grant damages in lieu of an injunction even before any damage has been done to the premises of the plaintiff (*Leeds Industrial Co-operative Society, Ltd. v. Slack*, 1924, A.C. 851). This jurisdiction is exercised only when the possible damage is certain to be small. (See EASEMENT.)

There is, in Scots law, no special doctrine as to "ancient lights." The servitude of light in Scotland is simply the Roman servitude *non officiendi luminibus vel prospectui*. (See EASEMENT and ROMAN LAW.) The same observation applies to the Code Civil and other European codes based on it. The doctrine as to ancient lights does not prevail generally in the United States. In a considerable number of the more important British dominions the acquisition of a prescriptive right to light and air has been abolished.

ANCILLARY (Lat. *ancilla*, a handmaid), an adjective meaning "subordinate to" or "merely helping," as opposed to "essential." Thackeray and some other writers have also employed it rather affectedly in its primary meaning of "pertaining to a maid-servant."

ANCILLON, CHARLES (1659–1715), one of a distinguished family of French Protestants, was born on July 28 1659, at Metz. His father, David Ancillon (1617–1692), was obliged to leave France on the revocation of the Edict of Nantes, and became pastor of the French Protestant community in Berlin. Charles Ancillon studied law at Marburg, Geneva and Paris, where he was called to the bar. In 1699 he succeeded Pufendorf as historiographer to the elector, and the same year replaced his uncle Joseph Ancillon as judge of all the French refugees in Brandenburg. He died on July 5 1715. Ancillon's chief claim to remembrance is the work that he did for education in Prussia, and the share he took, in co-operation with Leibnitz, in founding the Academy of Berlin. Of his works the only one still of value is the *Histoire de l'établissement des Français réfugiés dans les états de Brandebourg* (1690).

ANCILLON, JOHANN PETER FRIEDRICH (1766–1837), Prussian historian and statesman, great-grandson of Charles Ancillon, was born at Berlin, April 30 1766. He studied theology at Geneva, and after finishing his course was appointed minister to the French community at Berlin. Ancillon wrote a *Tableau des révolutions du système politique de l'Europe depuis le XV^e siècle* (1803; new ed. 1824), which gained him the eulogium of the Institute of France, and admission to the Academy of Berlin. It was the first attempt to recognize psychological factors in historical movements, but otherwise its importance was exaggerated. In 1808 he was appointed tutor to the royal princes, in 1809 councillor of state in the department of religion, and in 1810 tutor of the Crown Prince (afterwards Frederick William IV.), on whose sensitive and dreamy nature he was to exercise a powerful but far from wholesome influence. In Oct. 1814, when his pupil came of age, Ancillon was included by Prince Hardenberg in the ministry, with a view to utilizing his supposed gifts as a philosophical historian in the preparation of the projected Prussian Constitution. But the practical difficulty of the constitutional problem gave the "court parson"—as Gneisenau had contemptuously called him—excuse enough for a change of front which, incidentally, would please his exalted patrons. He became the soul of the reactionary movement at the Berlin court, and the faithful henchman of Metternich in the general politics of Germany and of Europe.

In 1818 Ancillon became director of the political section of the ministry for foreign affairs under Count Bernstorff, and in the spring of 1832, on Bernstorff's retirement, succeeded him as head of the ministry. Ancillon had convinced himself that the rigid class distinctions of the Prussian system were the philosophically ideal basis of the State, and that representation "by estates" was the only sound constitutional principle; his last and indeed only act of importance as minister was his collaboration with Metternich in the Vienna Final Act of June 12 1834, the object of which was to rivet this system upon Germany forever. He died on April 19 1837, the last of his family. His historical importance lies neither in his writings nor in his political activity, but in his personal influence at the Prussian court, and especially in its lasting effect on the character of Frederick William IV.

See C. A. L. P. Varnhagen von Ense, *Blätter aus der preussischen Geschichte* (Leipzig, 1868–69); *ib. Tagebücher*, vol. i. (Leipzig, 1861); H. O. Treitschke, *Deutsche Geschichte* (Leipzig, 1879–94), and essay on Ancillon in *Preussische Jahrbücher* for April 1872; *Allgemeine Deutsche Biographie*, s.v. (Leipzig, 1875).

ANCÓN, a small village and bathing-place on the coast of Peru, 22m. N. of Lima by rail. The bay is formed by two projecting headlands and is one of the best on the coast. It has a gently sloping beach of fine sand and has been a popular bathing-place since the time of President Balta, although the country behind it is arid and absolutely barren. At some time previous to the discovery of America, Ancón had a large aboriginal population. Traces of terraces on the southern headland can still be seen,

and the sand-covered hills and slopes overlooking the bay contain extensive burial-grounds which were systematically explored in 1875 by W. Reiss and A. Stübel (see Reiss and Stübel's *The Necropolis of Ancón in Peru*). In modern times Ancón has been the scene of several important historical events. Its anchorage was used by Lord Cochrane in 1820 during his attacks on Callao; it was the landing-place of an invading Chilean army in 1838; was bombarded by the Chileans in 1880; and in 1883 it was the meeting-place of the Chilean and Peruvian commissioners who drew up the Treaty of Ancón, which ended the war between Chile and Peru.

ANCON, the anatomical name for "elbow" (from the Gr. ἄγκων); "ancones" in architecture are the projecting bosses left on stone blocks or on drums of columns, to allow of their being either hoisted aloft or rubbed backwards and forwards to obtain a fine joint; the term was also given to the trusses or console brackets on each side of the doorway of a Greek or Roman building. A particular sort of sheep, with short crooked forelegs, is called "ancon" sheep.

ANCONA, ALESSANDRO (1835-1914), Italian man of letters, was born at Pisa on Feb. 20 1835 and died at Florence on Nov. 8 1914. He acted as intermediary between Cavour and the Tuscan Liberals in 1855, and represented Tuscany in the Società Nazionale. In 1861 he was appointed professor of Italian literature at Pisa, and was made a senator in 1904.

His chief works are: *Opera di Tommaso Campanella* (Turin, 1854); *Sacre Rappresentazioni dei secoli XIV., XV., e XVI.* (Florence, 1872); *Origini del Teatro in Italia* (Florence, 1877); *La Poesia popolare italiana* (Livorno, 1878), besides several volumes of literary essays, editions of the works of Dante and other early Italian writers, etc.

ANCONA, the Marches, Italy, an episcopal see and capital of the province of Ancona, on the north-east coast of Italy, 185m. N.E. of Rome by rail and 132m. direct, and 127m. S.E. of Bologna. Pop. (1921) 51,575 (town) 66,291 (commune). The town stands on and between the steep slopes of the two extremities of the promontory of Monte Conero, Monte Astagno to the south, occupied by the citadel, and Monte Guasco to the north, on which the cathedral stands (300ft.). The latter, dedicated to S. Ciriaco, is said to occupy the site of a temple of Venus, mentioned by Catullus and Juvenal as the tutelary deity of the place and 14 columns in the interior are attributed to it. It was consecrated in 1128 and completed in 1189. It is fine Romanesque in grey stone, in the form of a Greek cross, with a dodecagonal dome over the centre. The façade has a Gothic portal. The interior, with a crypt in each transept, preserves its original character. In the dilapidated episcopal palace Pope Pius II. died in 1464. S. Maria della Pizza has an elaborate arcaded façade (1210). The Palazzo del Comune (twice restored) with lofty arched substructures at the back, was the work of Margaritone d'Arezzo (1270). Fine late Gothic buildings include churches of S. Francesco and S. Agostino, the Palazzo Benincasa, and the Loggia dei Mercanti, all by Giorgio Orsini, usually called da Sebenico and the prefecture, which has Renaissance additions. The portal of S. Maria della Misericordia is ornate early Renaissance. There is an important archaeological museum.

To the east of the town is the harbour, now an oval basin of 990 by 880 yards, which, though small, is the finest harbour on the south-west coast of the Adriatic, and one of the best in Italy; improvements are in progress. It was originally protected only by the promontory on the north from the elbow-like shape of which (Gr. ἄγκων) the ancient town, founded by Syracusan refugees about 390 B.C., took the name which it still holds. Greek merchants established a purple factory here (Sil. Ital. viii. 438). Even in Roman times it kept its own coinage and continued the use of the Greek language. When it became a Roman colony is doubtful. It was occupied as a naval station in the Illyrian War of 178 B.C. Caesar took possession of it immediately after crossing the Rubicon. Its harbour was of considerable importance in imperial times as the nearest to Dalmatia, and was enlarged by Trajan, who constructed the north quay. It was his starting point for his second expedition to Moesia and Dacia in A.D. 105. At the beginning of it stands the marble triumphal arch, erected in his honour in A.D. 115. Pope Clement II. prolonged the quay, and an inferior imita-

tion of Trajan's arch was set up; he also erected a lazaretto at the south end of the harbour, now a tobacco warehouse, Vanvitelli being the architect-in-chief. The southern quay was built in 1880, and the harbour is now protected by forts on the heights. Steamers run regularly to Zara and Fiume and also to Gravosa. The imports and exports (but mainly the former) in 1921 amounted to 373,000 tons. There is a large sugar refinery and a shipbuilding yard. In 1926 the port dealt with 605,562 tons of merchandise, and 4,568 ships of tonnage 1,912,774, carrying 31,073 passengers.

Ancona was attacked by Goths, Lombards and Saracens, but recovered its importance. It was one of the cities of the Pentapolis under the exarchate of Ravenna, the other four being Fano, Pesaro, Senigallia and Rimini, and eventually became a semi-independent republic under papal protection until Gonzaga took possession for Clement VII. in 1532. From 1797 onwards, when the French took it, it frequently appears in history as an important fortress, until Lamoricière capitulated here on Sept. 29, 1860, eleven days after his defeat at Castelfidardo. It suffered some damage from bombardment by the Austrian fleet on May 24, 1915.

ANCONA, a variety of domestic fowl, very similar to the Leghorn. The Ancona originated in Port Ancona, Italy, and was imported into England about the middle of the last century, and thence to America. It lays a white-shelled egg, and is a non-broody breed. There are two varieties, the Single Comb and the Rose Comb Ancona which, apart from the type of comb, are identical in every respect. The general plumage colour is lustrous black above with certain of the feathers tipped with a v-shaped white tip and slate below. (See POULTRY.)

ANCREN RIWLE, a Middle English prose treatise written for a small community of three religious women and their servants. It is generally supposed to date from the first quarter of the 13th century, but E. Kölbing is inclined to place the Corpus Christi ms. about the middle of the 12th century. There are extant eight English mss. of the work (two fragmentary), four in Latin and one in French. One Latin ms., *Regula Anachoritarum sive de vita solitaria* (Magdalen college, Oxford, No. 67, fol. 50) has a prefatory note:—*Hic incipit prohemium venerabilis patris magistri Simonis de Gandavo, episcopi Sarum, in librum de vita solitaria, quem scripsit sororibus suis anachoritis apud Tarente*. But Bishop Simon of Ghent, who died in 1315, could not have written the book, though he may have been responsible for the Latin recension. It has been tentatively attributed to Richard Poor, bishop successively of Chichester, Salisbury and Durham; but the claim rests on slight foundation.

What was the original language of the *Ancren Riwle*? Morton held that it was English, but his view was challenged by E. E. Bramlette in *Anglia* (XV. 478-498), who argued in favour of a Latin original. Bramlette was, in his turn, challenged by G. C. Macaulay (*Modern Language Review*, IX, 70-78) who showed conclusively that the Latin was translated from English, and not vice versa; but after study of the French ms. (Cotton Vitellius F. vii) Macaulay argued that the English was translated from the French. But the evidence in favour of English cannot really be resisted. What is important, however, about the *Ancren Riwle*, is not the quantity of dispute it occasions, but the fact that it is a genuine contribution to English literature—almost the earliest English prose work that the ordinary person can read with pleasure. It combines religious sincerity with simple, affectionate charm in a singularly high degree.

Ancren Riwle was edited for the Camden Society by the Rev. James Morton in 1853 from the Cotton ms. (Nero A xiv.). A collation of this text with the ms. by E. Kölbing is printed in the *Jahrbuch für romanische u. engl. Spr. und Lit.* xv. 180 seq. (1876). The *Ancren Riwle* (ed. F. A. Gasquet, 1905) is available for the ordinary reader in *The King's Classics*. For specimens of texts and discussions of details see, in addition to works quoted, Kölbing in *Englische Studien*, lii. 535; Panes in *Englische Studien*, xxx. 344-346; McNabb in *Modern Language Review*, xi. 1-8, claiming a Dominican, Friar Robert Bacon, as author; Miss Hope Allen in *Publications of the Modern Language Association of America*, xxxiii. 538-546, suggesting that the work was written for three ladies of Kilburn; Miss Dorothy Dymes in *Essays and Studies by Members of the English Association*, Vol. ix.; R. W. Chambers and others in *Review of English Studies*, Jan. 1925, Jan. 1926, April 1926; and Joseph Hall, *Selections from Early Middle English*.

ANCRUM, a village on Ale or Alne Water, a tributary of the Teviot, Roxburghshire, Scotland. Pop. (1931) 858. The name has a Gaelic root and the village is of considerable antiquity; a Roman road forms the north-east boundary of the parish. Ancrum Moor, 2m. N.W., was the scene of a battle in 1545 in which the English were defeated by the Scots.

ANCUS MARCIUS (640–616 B.C.), fourth legendary king of Rome. Like Numa, his reputed grandfather, he was a friend of peace and religion, but was obliged to make war to defend his territories. He conquered the Latins, and some of them whom he settled on the Aventine formed the origin of the Plebeians. He fortified the Janiculum, threw a wooden bridge across the Tiber, founded the port of Ostia, established salt-works and built a prison.

See Livy i. 32, 33; Dion Halic. iii. 36–45; Cicero, *De Republica*, ii. 18.

ANCYLOPODA or **CHALICOTHEROIDEA**, a group of extinct large-bodied herbivorous mammals distinguished by the combination of large claws on the feet with herbivorous molar teeth of the type technically known as bunolo-pho-selenodont (cone-ridge-crescent tooth). The first known remains of these animals consisted of a large claw-like bone found in the Upper Miocene formation near Eppelsheim, Germany. This was pronounced by Cuvier in 1825 to represent "*un pangolin gigantesque*." Similarly, in North America the claw-like bones now known to pertain to *Moropus* (see below) were at first believed to have belonged to edentates, but the entire group is now known to consist of strangely modified hoofed mammals belonging to the order Perissodactyla (*q.v.*).

Through recent discoveries the best known member of the group is *Moropus elatus*, nearly complete skeletons of which, from the Lower Miocene of western Nebraska, are exhibited in the natural history museums of New York and Pittsburgh. This animal stood about 6ft. high at the shoulders. In general appearance it somewhat resembled a large horse, especially in the head and neck; but the feet were short, each ending below in three clawed digits, the claw on the inner side of the forefoot (corresponding to the nail of the second finger of the human hand) being greatly enlarged. Very possibly these claws (which represent highly modified hoofs rather than true claws) were used in scraping the ground in search of food or water. The front teeth or incisors were small and the canine teeth reduced. In the upper molar teeth the crown pattern exhibited a combination of crests and hillocks across which the U-shaped lower molars moved. The skull and dentition exhibit a curious combination of characters found elsewhere separately among the horses and earlier titanotheres, to both of which families the chalicotheres are remotely related. The earliest known member of the group (*Eomoropus*) occurs in the middle Eocene of Wyoming. It was about as large as a sheep. Its skull and teeth, while clearly foreshadowing those of *Moropus*, also indicate its derivation from still older and more primitive perissodactyls. Among the later members of the group *Macrotherium magnum* was a beast of elephantine bulk. The known range of the group was from the middle Eocene of Wyoming to the Pliocene of China.

See H. F. Osborn, "*Eomoropus*, an American Eocene Chalicotheres," *Bull. Amer. Mus. Nat. Hist.*, vol. xxxii, p. 261 (1913); W. J. Holland and O. A. Peterson, "The Osteology of the Chalicotheroidea," *Memoirs of the Carnegie Museum*, vol. iii, No. 2 (1914).

(W. K. G.)

ANCYRA, an ancient city of Galatia (mod. *Angora*, *q.v.*), in Asia Minor, on a tributary of the Sangarius. Originally a prosperous Phrygian city, Ancyra became the centre of the Tectosages, one of the three Gaulish tribes that settled in Galatia about 232 B.C. In 189 B.C. Ancyra was occupied by Cn. Manlius Vulso, who made it his headquarters in his operations against the tribe. In 63 B.C. Pompey placed it (together with the Tectosagan territory) under one chief, and it continued under native rule till it became the capital of the Roman province of Galatia in 25 B.C. Inscriptions and coins show that its civilization in the 1st century A.D. consisted of a layer of Roman ideas and customs super-imposed on Celtic tribal characteristics, and that not until about A.D. 150 did the true Hellenic spirit begin to appear. Christianity was introduced (from the north or north-west) perhaps as early as the

1st century, but there is no shred of evidence that the Ancyran Church (first mentioned A.D. 192) was founded by St. Paul or that he ever visited northern Galatia. The real greatness of the town dates from the time when Constantinople became the Roman metropolis, when its situation gave it an importance which it retained throughout the middle ages. See further **ANGORA** (1). An important ecclesiastical synod was held here in A.D. 314.

The modern town contains many remains of Roman and Byzantine periods. The most important monument is the *Augusteum*, a temple of white marble erected to "Rome and Augustus" during the lifetime of that emperor by the common council or diet of the three Galatian tribes. The temple was afterwards converted into a church, and in the 16th century a fine mosque was built against its south face. On the walls of the temple is engraved the famous *Monumentum Ancyranum*, a long inscription in Latin and Greek describing the *Res gestae divi Augusti*. The inscription is a grave and majestic narrative of the public life and work of Augustus. The original was written by the emperor in his 76th year (A.D. 13–14) to be engraved on two bronze tablets placed in front of his mausoleum in Rome.

Galatia* (1899); Babelon-Reinach, *Recueil général d'A.M.* See also **GALATIA**.

ANCYRANUM, MONUMENTUM, the tablets recording the deeds of Augustus, found on the walls of a temple at Ancyra (Angora). These tablets were copies of the *index rerum a se gestarum* (record of his deeds) set up by the emperor in Rome. The first section deals with the "deeds," largely military, between 44 and 28 B.C.; the second with domestic matters, such as honorific titles and constitutional changes; the third with finance; and the fourth with general political and diplomatic matters. It is one of our most important historical sources for this period.

See the editions by Th. Mommsen (1883) and E. G. Hardy (1923).

ANDALUSIA (Span. Andalucía), one of the old provinces of Spain, broken up in 1833 into the eight modern provinces of Almería, Cadiz, Cordova, Granada, Huelva, Jaén, Malaga and Seville (*q.v.*).

The Arab name al-Andalus designated the entire peninsula, but was used also specifically for the Muslim area and especially for the four kingdoms of Seville, Cordova, Jaén and Granada. It has been referred to a hypothetical form Vandalicia, the name either of Baetica when occupied by the Vandals or of the port by which the Vandals passed to Africa. The alternative "Land of the West" seems not to be considered seriously by modern Arabic scholars. In popular speech, however, Andalusia begins, not with the northern boundaries of the provinces of Cordova and Seville, but with the descent from the Sierra Morena to the Guadalquivir lowlands. Here is one of the abrupt changes characteristic of Spain; everything changes—climate, vegetation and people—in the drop of 1,500 to 2,000ft. from the plateau to the lowlands. These wide and undulating lowlands are the essential Andalusia; the foothills of the Cordillera which separates them from the Mediterranean, and the Cordillera itself are known in distinction as Upper Andalusia. (Nevertheless, the terms Upper and Lower Andalusia are used also to distinguish between the lowlands lying respectively along the upper and lower courses of the Guadalquivir.) Lower Andalusia opens out gradually in a funnel as it descends towards the Atlantic, at the same time it slopes gently towards the Guadalquivir, which on the north clings to the Morena foot. It is the upheaved bottom of the sea-straits which formerly separated the Spanish plateau from the Cordillera to the south, at that time still connected across the present Straits of Gibraltar with the African continent. The movement of upheaval, which led to the steady westward growth of the land, had many oscillations, so that deposits of widely differing kinds were laid down on the ocean margin as defined from time to time. Moreover, the older levels which appear at the surface where these latter deposits have been worn away often contain gypsum and salt. Thus the soils of Lower Andalusia vary widely from the fertile

marls, which are best known in the famous olive-groves of the *Ajaraque*, west of Seville, and in the vineyards of Jeréz, de la Frontera to the waterless, infertile soils of the wide pasture tracts (*dehesas*). To the west Lower Andalusia rises into the highly mineralized plateau leading to Portugal; to the east the lowlands, and with them the name, disappear in the narrows of the old straits, now limestone highlands leading to Murcia; in this direction the esparto and saline steppes increasingly dominate the landscape.

The excessive heat and almost absolute drought of the summer months and the mildness of winter differentiate the climate of Lower Andalusia from that of the other arid districts of Spain. The amazingly fertile "black earths," which cover large tracts south of the Guadalquivir below Cordova and the La Janda depression east of Cape Trafalgar, have no reference to present climatic conditions; they are residual soils from an earlier, pluviose phase. The present climate is reflected in the wide extension of the olive, in the restricted extension of the orange from the coast to Palma del Río, but more especially in the frequent hedges of prickly-pear, and the varieties of cactus. The towns of Lower Andalusia lie on the rivers, usually at points where these may be suitably bridged (Seville, Ecija, Cordova), or on elevations rising from the plain (Carmona, Marchena, Baena), or in commanding positions on the borders of the foothills (Morón, Osuna, Lucena). Cadiz, however, lies on the coast on a narrow-necked peninsula. Between the Rio Tinto and the Guadalquivir a large area of marsh-lands, fringed with dunes along the coast, is practically uninhabited.

Upper Andalusia rises somewhat abruptly from the south side of the Guadalquivir lowlands, but as these rise towards the narrows its boundary becomes less distinct. The sierras of Upper Andalusia are aligned roughly in a cordillera, for the origin and structure of which see general article SPAIN, under heading *Geology*. They culminate in the Sierra Nevada (*q.v.*). A series of structural depressions, aligned with the sierras, provides most of the flat ground in this mountainous country, and the cities and towns are situated to command these (Granada, Antequera, Guadía and Baza), or on the coastal plains at the mouths of the short rivers of the Mediterranean slope (Málaga, Matril, etc.). The *vegas*, or fertile flats, of this area are thus unusually important. The climates of Upper Andalusia are altitudinal variants of that of Lower Andalusia. The towns of the mountain and of the coast are both, for different reasons, tolerable in summer. The coastal strips are notable for the mildest winter climate in Europe; here are to be found the sugar-cane, the plantain, the cherimoya, even the coffee-plant, and cotton is now being re-introduced experimentally under Government control. Between the sub-tropical coastal district and the Nevada summits, lying some 500 or 600 ft. below the theoretical snow-line, there is a great range of climates and vegetations, which are brought into close superposition in the Alpujarras (*q.v.*). Nowhere, however, is there significant rainfall in summer; the only advantage possessed by Upper Andalusia over the lowlands is the availability of water for irrigation.

The accessibility of the interior by the waterways of the Guadalquivir (the only important river of Spain for navigation) and, to a lesser extent, of the Odiel and Rio Tinto, together with the mineral wealth of the Sierra Morena and of the plateau leading to Portugal, contributed to the early advance of civilization in Andalusia and to early contact with the outside world. The kingdom of Tartessus, perhaps the Biblical Tarshish, flourished here in the latter half of the second millennium B.C., and its port, of the same name, on the Atlantic front served both as depot for the ore of Andalusia and as *entrepôt* for the tin of northern lands, brought here in Tartessian ships. The Phoenicians, who may have been preceded here by the Cretans, established about 1100 B.C. a colony, Gadir, the earliest Cadiz, on a small coastal islet at some distance south, and also tapped the resources of Andalusia at points on the Mediterranean coast (Málaga, Adra). The Phoenicians were followed—after an interval during which the Phocæan Greeks controlled the trade with Tartessus—by the Carthaginians, who destroyed the Tartessian kingdom and finally established themselves firmly in southern Spain. Andalusia

did not blossom again until, as the senatorial province of Baetica (which extended, however, farther north and reached east only to the Linares district), it became integrally Roman. The brief occupation by the Vandals in the 5th century A.D., and the failure of the Eastern empire to hold Andalusia as an outlier of the imperial territory in Africa, seem to illustrate the untenability of Andalusia by a power not firmly established on the central plateau of Spain. The Muslim period, beginning in 711, brought Lower Andalusia to the highwater mark of its history. Cordova, more conveniently situated with respect to the Morena passes than the other Andalusian towns, became under the Umayyads the chief centre of authority in the peninsula and a world-centre of culture. But the disadvantages, for control of the peninsula, of an administrative centre in Andalusia required to be counteracted by the energy of an Abderrahman III. or an Almanzor, and with the death of the latter effective control from Cordova and, for the time, from Andalusia ceased. In the succeeding period superior local advantages of site contributed to make Seville outstanding among the numerous small Muslim states of Spain. When, after the defeat at Las Navas de Tolosa in 1212, the Muslims lost control of the Despeñaperros pass, and their Guadiana states, now outflanked, fell to the Christians, Lower Andalusia ceased to be tenable.

The Muslim concentration in Upper Andalusia from 1257 onwards brought that region in turn to the zenith of its historical destiny. Granada, dominating the Genil depression, the most central of the Cordillera, became the centre of authority for a kingdom extending from Algeciras to the neighbourhood of Aguilas. To the loose coherence of the kingdom of Granada, regarded as ending Arab civilization, the physical isolation of the local administrative centres of Málaga, Almería, Guadix, Baza, etc., and the lack of continuous lines of easy communication contributed obviously.

It has been suggested, particularly by Dr. Vaughan Cornish, that an important mistake was made by the Catholic sovereigns at the close of the reconquest in failing to recognize the suitability of Seville to be the capital of reunited Spain (see article SPAIN). With the discovery of the New World the water-front of Andalusia rose to a new importance. First Seville, and later Cadiz, controlled the American trade. The tedious navigation of the lowest reaches of the Guadalquivir and the isolated position of Cadiz contributed to the decline of this trade in Andalusia when the monopoly was withdrawn from these cities. Canalization and other improvements effected on the Guadalquivir have revived the foreign trade of Seville during the last 40 years; the outlook to the ocean is again an important factor in the life of Lower Andalusia. The 19th century mining revival, under foreign concessionaire companies, has brought into play again another traditional factor. In Upper Andalusia modern development is largely a question of communications; the proposed railway from Granada to Motril will stimulate development in the heart of this region.

The long period of Muslim domination in Andalusia has left behind four great monuments—the Giralda and Alcázar of Seville, the Mosque of Cordova and the Alhambra at Granada. Though the buildings which survive from that period are few, the impress of the Muslim is still clear in the plan of cities and towns where, as in Cordova, later economic currents have not been sufficiently strong to modify it seriously, and is everywhere traceable. The internal arrangement of the house is derived by evolution from the Arab interior. The influence of Arabic in the everyday language of the common people is obvious, but it is not possible to assess the relative parts played by physical environment and the successive immigrations in determining the "Gascon" temperament of the people, the physical type—dark complexioned, handsome, graceful, and the clipped speech and phonetic peculiarity of the *sese*, or sibilant of the lisped Castilian *c* and *z*. The extension of the *sese* in the New World is a testimony to the part played by Andalusia in its settlement.

Calvert, *Moorish Remains in Spain* (undated); Théophile Gautier, *Voyage en Espagne*, trans. under the title, *A Romantic in Spain* (1926).

ANDALUSIA, a city of southern Alabama, U.S.A., on the Central of Georgia and the Louisville and Nashville railways; the county seat of Covington county, and the commercial centre of a farming and lumbering region. The population was 551 in 1900; 4,023 in 1920; 5,154 in 1930. The city's manufactures include sashes and doors, paint, pickles and turpentine.

ANDALUSITE, a mineral with the same chemical composition as kyanite and sillimanite, being aluminium silicate, Al_2SiO_5 . As in sillimanite, its crystalline form is referable to the orthorhombic system. Crystals of andalusite have the form of almost square prisms, the prism-angle being $89^\circ 12'$. As a rule the crystals are roughly developed and rude columnar masses are common, these being frequently partially altered to kaolin or mica. Such crystals, opaque and of a greyish or brownish colour, occur abundantly in the mica-schist of the Lisens Alp near Innsbruck in Tirol, and in Andalusia, from which place it derives its name. The unaltered mineral is found as transparent pebbles with topaz in the gem-gravels of the Minas Novas district, in Minas Geraes, Brazil. These pebbles are usually green but are sometimes reddish-brown in colour and are remarkable for their very strong dichroism, the same pebble appearing green or reddish-brown according to the direction in which it is viewed. Such specimens make very effective gem-stones, the degree of hardness of the mineral ($H. = 7\frac{1}{2}$) being quite sufficient for this purpose.

A curious variety of andalusite known as chiastolite is specially characteristic of clay-slates near a contact with granite. The elongated prismatic crystals enclose symmetrically arranged wedges of carbonaceous material, and in cross-section (*see fig.*) show a black cross on a greyish ground. Cross-sections of such crystals are polished and worn as amulets or charms. Crystals of a size suitable for this purpose are found in Brittany and the Pyrenees, while still larger specimens have been found recently in South Australia.

ANDAMANESE. The Andaman islands in the Bay of Bengal are inhabited by a pigmy stock. The men average 4ft. 10½ in., the women, 4ft. 6 in. They are markedly round headed, broad nosed, with hair generally sooty black or yellowish brown. The skin varies in colour from an intense sheeny black to reddish brown on the unexposed parts.

There are two main divisions, coast and inland people, each divided into minor local groups with definite linguistic and cultural characteristics. There are no clans or exogamic units. There is no organized government or hereditary chief. Conduct is regulated by public opinion, the direct pressure of which, in small nomadic, hunting, food-collecting groups, is effective. The stages of life are marked by a series of rites centring on food taboos. Marriage rites consist simply of publicly placing the bride on the bridegroom's lap. The encampment has separate huts for the unmarried—girls and boys apart, and for married couples. Four modes of burial are practised, tree burial being employed for those who are specially honoured. Dancing is practised, and singing, individual and collective, is cultivated. Religious beliefs are associated with the seasonal variations, the monsoon being the prominent and regulating feature. Legends display local variations. Religious ritual is not organized. Men have visions or dreams and gain reputation as in contact with the world of

spirits. Though ignorant of methods of making fire, they preserve it carefully, cook by it and make pottery.

Language.—The languages of the ten tribes of the Great Andaman form a linguistic group distinct from that constituted by the languages of the Little Andaman and the Jarawa of the South Andaman. The vocabularies differ conspicuously, but the identities of grammatical structure show that all are derived from a common source. The phonetic system is imperfectly known, but there is no *s*, *z*, *sh* or *zh*. Vowel and consonantal changes follow regularly in the several languages. The language is built up of stems and affixes. Simple stems are generally nouns, names of simple independently existing objects. Compound stems have a prefix, which is a separable element. The prefixes show that the object is a part of, or intimately associated with, some other object. A pig is an independent object. It is a simple stem. The head of a pig is not a simple object. A class prefix is therefore required. Such objects belong to someone; a head belongs to someone. A possessory prefix is therefore required. The class prefixes also modify the meaning of the stem. Adjectives do not require a possessory prefix but do require a class prefix. Simple verbs consist of a stem and a radical prefix and must be preceded by a personal pronoun. Compound words contain more than one stem. The elements may be (1) two simple stems, (2) two compound stems, (3) simple stem plus compound stem, (4) compound stem plus simple stem. It is recorded that many words could not be analysed so that the methods of word formation may include methods not stated above. The use of specific terms to describe details regarded by them as important is carried very far. Words for one and two are known. Finger counting is employed. Ten or both hands mean all, which is also used when five is reached by fingers. The grammatical construction proceeds on logical lines. There is as yet no convincing proof of any relationship with other languages.

ANDAMAN ISLANDS, a group of islands in the Bay of Bengal. Large and small, they number 204, and lie 590m. from the mouth of the Hugli, 120m. from Cape Negrais in Burma, the nearest point of the mainland, and 340m. from the northern extremity of Sumatra. The extreme length of the Andaman group is 219m. with an extreme width of 32 miles. The main part of it consists of a band of five chief islands, so closely adjoining and overlapping each other that they have long been known collectively as "the Great Andaman." Four narrow straits part these islands. Attached to the chief islands are, on the extreme north, Landfall Islands; Interview Island, off the west coast of the Middle Andaman; the Labyrinth Island off the south-west coast of the South Andaman; Ritchie's (or the Andaman) archipelago off the east coast of the South Andaman and Baratang. Little Andaman, roughly 26m. by 16, forms the southern extremity of the whole group and lies 31m. south of Rutland Island across Duncan Passage, in which lie the Cinque and other islands, forming Manners Strait, the main commercial highway between the Andamans and the Madras coast. Besides these are a great number of islets lying off the shores of the main islands. The land area of the Andaman Islands is 2,508 sq. miles.

Topography.—The islands forming Great Andaman consist of a mass of hills enclosing very narrow valleys, the whole covered by an exceedingly dense tropical jungle. The hills rise, especially on the east coast, to a considerable elevation; the highest being Saddle Peak (2,400ft.) in the North Andaman. Little Andaman, with the exception of the extreme north, is practically flat. There are no rivers and few perennial streams in the islands. The scenery is everywhere strikingly beautiful and varied, and the coral beds of the more secluded bays in its harbours are conspicuous for their exquisite colouring. The coasts of the Andamans are deeply indented, giving existence to a number of safe harbours and tidal creeks, often surrounded by mangrove swamps. The chief of several capacious harbours is Port Blair in South Andaman: and there are a number of good anchorages along the coast.

TRANSVERSE SECTION OF A CRYSTAL OF CHIASTOLITE

A variety of andalusite with black inclusions. The crystal sections, when polished, are worn as amulets or charms

Geology.—The Andaman islands form part of a lofty range of submarine mountains, 700m. long, running from Cape Negrais in the Arakan Yoma range of Burma, to Achin head in Sumatra. This range separates the Bay of Bengal from the Andaman sea; and it contains much that is geologically characteristic of the Arakan Yoma, and formations common also to the Nicobars and to Sumatra and the adjacent islands. The older rocks are Early Tertiary or Late Cretaceous, but there are no fossils to indicate age. The newer rocks, common also to the Nicobars and Sumatra, are chiefly in Ritchie's archipelago and contain radiolarians and foraminifera.

Climate.—Rarely affected by a cyclone, though within the influence of practically every one that blows in the Bay of Bengal, the Andamans are of the greatest importance because of the accurate information relating to the direction and intensity of storms which can be communicated from them better than from any other point in the bay, to the vast amount of shipping in this part of the Indian ocean. A well-appointed meteorological station has been established at Port Blair since 1868. Speaking generally, the climate of the Andamans themselves may be described as normal for tropical islands of similar latitude. It is warm always, but tempered by pleasant sea-breezes; very hot when the sun is northing; irregular rainfall, but usually dry during the north-east, and very wet during the south-west monsoon.

Flora and Fauna.—A section of the Forest Department of India has been established in the Andamans since 1883, and in the neighbourhood of Port Blair 156 sq.m. have been set apart for regular forest operations which are carried on by convict labour. The chief timber of indigenous growth is padouk (*Pterocarpus dalbergioides*), used for buildings, boats, furniture, fine joinery and all purposes to which teak, mahogany, hickory, oak and ash are applied. This tree is widely spread and forms a valuable export to European markets. Other first-class timbers are koko (*Albizia Lebbek*), white chuglam (*Terminalia bialata*), black chuglam (*Myristica irya*), marble or zebra wood (*Diospyros kurzii*) and satin wood (*Murraya exotica*), which differs from the satin-wood of Ceylon (*Chloroxylon Swietenia*). All of these timbers are used for furniture and similar purposes. Among the imported flora are tea, Siberian coffee, cocoa, Ceara rubber (which has not done well), Manila hemp, teak, cocoanut and a number of ornamental trees, fruit-trees, vegetables and garden plants. The general character of the forests is Burmese with an admixture of Malay types. Great mangrove swamps supply unlimited firewood of the best quality.

Animal life is generally deficient throughout the Andamans, especially as regards mammalia, of which there are only nineteen separate species in all, twelve of these being peculiar to the islands. There is a small pig (*Sus andamanensis*), important to the food of the people, and a carnivore (*Paradoxurus tyleri*); but the bats and rats constitute nearly three-fourths of the known mammals. This paucity of animal life seems inconsistent with the theory that the islands were once connected with the mainland. Moreover, the Andaman species differ from those of the adjacent Nicobar islands. Each group has its distinct harrier-eagle, red-cheeked parakeet, oriole, sun-bird and bulbul. Fish are very numerous and many species are peculiar to the Andaman seas. Turtles are abundant and supply the Calcutta market.

The People.—The Andaman islands are the abode of savages as low in civilization as almost any known on earth. Our earliest notice of them is in a remarkable collection of early Arab notes on India and China (A.D. 851), which describes the islanders as cannibals who massacre ship-wrecked crews. The traditional charge of cannibalism has been very persistent; but it is entirely denied by the islanders themselves, and is now and probably always has been untrue. Of their massacres of shipwrecked crews, even in quite modern times, there is no doubt. The Andamanese are probably the relics of a pigmy race that once inhabited the south-east portion of Asia and its outlying islands, representatives of which are also still to be found in the Malay Peninsula and the Philippines. Their antiquity and their stagnation are attested by the remains found in their kitchen-middens, which lead to the belief that the Andamans were settled by their present inhabitants some time during the Pleistocene period, and certainly no

later than the Neolithic age. Though all descended from one stock, there are twelve distinct tribes, each with its own clearly-defined locality, its own distinct variety of the one fundamental language and to a certain extent its own separate habits. Every tribe is divided into septs fairly well defined. The average height of males is 4ft. 10½in.; of females, 4ft. 6in. The skin varies in colour from an intense sheeny black to a reddish-brown on the collarbones, cheeks and other parts of the body. The hair varies from a sooty black to dark and light brown and red. It grows in small rings, which give it the appearance of growing in tufts, though it is really closely and evenly distributed over the whole scalp. The figures of the men are muscular and well-formed and generally pleasing; but the women have a tendency to stoutness and ungainliness of figure, and sometimes to pronounced prognathism. The women's heads are shaved entirely and the men's into fantastic patterns. Yellow and red ochre mixed with grease are coarsely smeared over the bodies, grey in coarse patterns and white in fine patterns resembling tattoo marks. Tattooing is of two distinct varieties. In the south the body is slightly cut by women with small flakes of glass or quartz in zigzag or lineal patterns downwards. In the north it is deeply cut by men with pig-arrows in lines across the body. The male matures when about fifteen years of age, marries when about twenty-six, begins to age when about forty, and lives on to sixty or sixty-five if he reaches old age. Except as to the marrying age, these figures fairly apply to women.

The Andamanese are bright and merry companions, keen sportsmen, but when angered, cruel, jealous, treacherous and vindictive and always unstable—in fact, a people to like but not to trust. There is no idea of government, but in each sept there is a head, who has attained that position by degrees on account of some tacitly admitted superiority and commands a limited respect and some obedience. The young are deferential to their elders. Offences are punished by the aggrieved party. Property is communal and theft is recognized only as to things of absolute necessity, such as arrows, pigs' flesh and fire. Fire is the one thing they are really careful about, not knowing how to renew it. The religion consists of fear of the spirits of the wood, the sea, disease and ancestors, and of avoidance of acts traditionally displeasing to them. There is neither worship nor propitiation. Honour is shown to an adult when he dies by wrapping him in a cloth and placing him on a platform in a tree instead of burying him. At such a time the encampment is deserted for three months. The only known weapons are bows, which differ altogether with each group, but the same two kinds of arrows are in general use: (1) long and ordinary for fishing and other purposes; (2) short with a detachable head fastened to the shaft by a thong, which quickly brings pigs up short when shot in the thick jungle. Bark provides material for string, while baskets and mats are neatly and stoutly made from canes and buckets out of bamboo and wood. None of the tribes ever ventures out of sight of land, and they have no idea of steering by sun or stars. The Andaman languages are extremely interesting from the philological standpoint. They are agglutinative in nature, show hardly any signs of syntactical growth though every indication of long etymological growth, give expression to only the most direct and the simplest thought, and are purely colloquial and wanting in the modifications always necessary for communications by writing. The sense is largely eked out by manner and action.

For many years the Andamans have been the scene of a highly organized penal settlement to which life convicts and long-term convicts from India were sent; this was the "transportation" of the Indian penal code. The capital of the settlement is Port Blair, where a chief commissioner resides, in charge of the islands and also of the Nicobar group. He has a staff of assistants and overseers, mostly Europeans, and security is ensured by a small garrison of British and Indian troops and a battalion of Indian military police. The purpose of the settlement is largely reformatory. After a period of graduated labour, the well-behaved convict is given a ticket-of-leave and becomes self-supporting. He can live in one of the villages comprised in the settlement, farm, keep cattle, marry if he is single, or send to India for his family; but he must not leave the settlement or be idle. His children

receive elementary education; and there is ample hospital accommodation throughout the settlement. With approved conduct he may be released and sent home after 20 to 25 years of total "transportation"; and throughout that time a quasi-judicial procedure controls any punishments inflicted on him, and he is as sure of justice as if he were free. The total convict population of all grades used to be in the neighbourhood of 12,000. Since 1921, however, transportation has ceased; and the gradual abandonment of the settlement has been decided upon. In 1926 the convict population had fallen to just under 8,000. The many self-supporting convicts cannot well be transferred to imprisonment in India; and there is also a large free-born population who have made the islands their home; so that the policy is to extend the occupation of the islands for agricultural purposes on a voluntary basis. Good-conduct prisoners in the Indian jails will be allowed to transfer to the Andamans and take their families with them. A number of returned emigrants from Natal have elected to settle in the islands; and a batch of Karens have come over for forest work. The ticket-of-leave system has been extended, and grants of land with occupancy rights are being given. The area under cultivation has more than doubled since 1921, and exceeded 72,000 ac. in 1926. There are 18 schools in the settlement, and the attendance in 1926 included 228 children of convict parents.

HISTORY

Andaman first appears distinctly in the Arab notices of the 9th century. But it seems possible that the *Agathou daimonos nēsos* (Good Spirit Island) of Ptolemy was really a misunderstanding of some form like *Agdamān*. The islands are briefly noticed by Marco Polo (who probably saw without visiting them), under the name *Angamanain*, seemingly an Arabic dual, "The two Angamans," with the exaggerated but not unnatural picture of the natives, long current, as dog-faced Anthropophagi. Another notice occurs in the story of Nicolo Conti (c. 1440), who explains the name to mean "Island of Gold," and speaks of a lake with peculiar virtues as existing in it. The name is probably derived from the Malay *Handuman*, coming from the ancient *Hanuman* (monkey). Later travellers repeat the stories, too well founded, of the ferocious hostility of the people. In Sept. 1789 Captain Blair, acting under instructions from the Government of Bengal, established a penal colony, associated with a harbour of refuge on Chatham Island, in the south-east bay of the Great Andaman, now called Port Blair, but then Port Cornwallis. Two years later, urged by Admiral Cornwallis, the Government transferred the colony—together with its name of Port Cornwallis—to the north-east part of Great Andaman, where a naval arsenal was to be established. But the scheme did ill; and in 1796 the Government put an end to it. In 1839, Dr. Helfer, a German savant employed by the Indian Government, was attacked and killed in the islands. In 1844 the troop-ships "Briton" and "Runnymede" were driven ashore there. The natives showed their usual hostility, killing all stragglers. Outrages on shipwrecked crews continued so frequent that the question of occupation was revived, and in 1855 a project was formed for a settlement and a convict establishment. This scheme was interrupted by the Indian Mutiny of 1857, but as soon as the revolt was broken, it became more than ever urgent to provide such a resource, on account of the great number of prisoners falling into British hands. Lord Canning, therefore, despatched in Nov. 1857 a commission, headed by Dr. F. Mouat, to examine and report. The commission reported favourably, selecting as a site Blair's original Port Cornwallis, but avoiding the vicinity of a salt swamp which seemed to have been pernicious to the old colony. To avoid confusion, the name of *Port Blair* was given to the new settlement, which was established in the beginning of 1858. For some time sickness and mortality were excessively large, but the reclamation of swamp and clearance of jungle on an extensive scale by Col. Henry Man (1868–70) was ultimately successful. The Andaman colony obtained a tragic notoriety from the murder, by a Mohammedan convict, of the viceroy, the earl of Mayo, when on a visit to the settlement on Feb. 8, 1872. In the same year the two groups, Andaman and Nicobar—the occupation of the latter having been forced on the British Government

in 1869 by the continued outrages upon vessels—were united under a chief commissioner residing at Port Blair. Since that time the Islands have been continuously used as a convict settlement. The penal settlement however is being gradually discontinued, the islands being left to develop on free lines.

Portman, *Manual of the Andamanese Languages* (1888), *Record of the Andamanese* (11 vols. mss. in India Office, London, and Home Dept., Calcutta, 1893–98), *Notes on the Languages of the South Andaman Group of Tribes* (Calcutta, 1898), and *History of our Relations with the Andamanese* (Calcutta, 1899); Sir Richard C. Temple, *The Andaman and Nicobar Islands* (Indian Census, 1901); A. Alcock, *A Naturalist in Indian Seas* (1902); C. B. Kloss, *In the Andamans and Nicobars* (1908); A. R. Brown, *The Andaman Islanders* (1922).

ANDAMENTO (Ital.), a musical term signifying the longer and more extended type of fugal subject, as distinguished from that of the shorter and more compact kind, or *sogetto*, consisting of a single brief theme. By German writers however the term is more often applied, not to a fugue's subject matter, but to its episodes—another instance of the confusion of practice so often prevailing in the case of musical terminology.

ANDANTE, a musical term to indicate pace, coming between *adagio* and *allegro*; it is also used of an independent piece of music or of the slow movement in a sonata, symphony, etc. The diminutive form *andantino* is used, confusingly enough, to signify both less slow and less fast.

ANDAQUIAN, a small independent linguistic stock of South American Indians, so called from the Andaquis, its most important tribe. The Andaquis live on the eastern slope of the Cordillera Oriental in southern Colombia, on the Fragua and Ortegaza rivers, which form the sources of the Caqueta. They are said to have formerly lived on the western slope of the range, on the headwaters of the Magdalena and between it and the Suaza. In this region the remarkable ruins of San Augustin are located. The Andaquis are a warlike folk, and are but little known.

See M. M. Albis, *Los Indios del Andaquí* (Popayan, 1855).

ANDERIDA, an ancient Roman fort at Pevensey, near Eastbourne in Sussex (England), built about A.D. 300 as part of a scheme of land-defence against Saxon pirates; repaired probably by Stilicho, about A.D. 400; and utilized by William the Conqueror for a Norman castle. Its massive Roman enceinte still stands but little damaged.

ANDERMATT, a Swiss health resort and centre for winter sports, lying at a height of 4,700 ft. at the foot of the Gürschen, in the Urseren valley. The settlement is first mentioned in the 14th century, but remained unimportant until the opening of the St. Gotthard railway from Lucerne to Milan in 1882. It now ranks among the most famous Alpine resorts. Andermatt is also the chief military station of the St. Gotthard pass in one of the most elaborately fortified valleys in Europe.

ANDERNACH, a town in Rhenish Prussia, Germany, on the left bank of the Rhine, rom. N.W. of Coblenz. Pop. (1925), 10,790. *Antunnacum*, the Roman frontier station, was founded by Drusus. In 1109, Andernach received civic rights; in 1253 it joined the confederation of the Rhine cities, and was the most southern member of the Hanseatic league. In 1794, Andernach passed to France, but in 1815 was ceded, together with the left bank of the Rhine, to Prussia. It possesses old walls, a Romanesque parish church (12th century), a watch tower on the river and a Renaissance town hall. A famous crane, for lading merchandise, dates from 1554. Mat-making is one of the chief industries, and millstones of the local lava and tufa are exported. This product was much used by the Dutch in the construction of their dykes.

ANDERSEN, HANS CHRISTIAN (1805–1875), Danish poet and fabulist, was born at Odense, in Fünen, on April 2, 1805. He was the son of a sickly young shoemaker of 22 and his still younger wife; the whole family lived and slept in one little room. Andersen very early showed signs of imaginative temperament, which was fostered by the indulgence and superstition of his parents. In 1816 the shoemaker died and the child was left entirely to his own devices. He ceased to go to school; he built himself a little toy-theatre and sat at home making clothes for

his puppets and reading all the plays that he could borrow; among them were those of Holberg and Shakespeare. At Easter 1819 he was confirmed at the church of St. Knud, Odense, and began to turn his thoughts to the future. It was thought that he was best fitted to be a tailor; but as nothing was settled, and as Andersen wished to be an opera-singer, he took matters into his own hand and started for Copenhagen in Sept. 1819. There he was taken for a lunatic, snubbed at the theatres, and nearly reduced to starvation; but he was befriended by the musicians Christoph Weyse and Siboni, and afterwards by the poet Frederik Hoëgh Guldberg (1771-1852). His voice failed, but he was admitted as a dancing pupil at the Royal Theatre. He grew idle and lost the favour of Guldberg, but a new patron appeared in the person of Jonas Collin, the director of the Royal Theatre, who became Andersen's life-long friend. King Frederick VI. was interested in the strange boy and sent him for some years, free of charge, to the great grammar-school at Slagelse. Before he started for school he published his first volume, *The Ghost at Palnatøke's Grave* (1822). Andersen, a very backward and unwilling pupil, actually remained at Slagelse and at another school in Elsinore until 1827; these years, he said, were the darkest and bitterest in his life. Collin at length consented to consider him educated, and Andersen came to Copenhagen. In 1829 he made an appreciable success with a fantastic volume entitled *A Journey on Foot from Holman's Canal to the East Point of Amager*, and he published in the same season a farce and a book of poems. He thus suddenly came into request at the moment when his friends had decided that no good thing would ever come out of his early eccentricity and vivacity. He made little further progress, however, until 1833, when he received a small travelling stipend from the king and made the first of his long European journeys. At Le Locle, in the Jura, he wrote *Agnate and the Mermaid*; and in Oct. 1834 he arrived in Rome. Early in 1835 Andersen's novel, *The Improvisatore*, appeared and achieved a real success; the poet's troubles were at an end at last. In the same year, 1835, the earliest instalment of Andersen's immortal *Fairy Tales* (Eventyr) was published in Copenhagen. Other parts, completing the first volume, appeared in 1836 and 1837. The value of these stories was not at first perceived, and they sold slowly. Andersen was more successful for the time being with a novel, *O.T.*, and a volume of sketches, *In Sweden*; in 1837 he produced the best of his romances, *Only a Fiddler*. He then turned his attention, with but ephemeral success, to the theatre, but was recalled to his true genius in the charming miscellanies of 1840 and 1842, the *Picture-Book without Pictures* and *A Poet's Bazaar*. Meanwhile the fame of his *Fairy Tales* had been steadily rising; a second series began in 1838, a third in 1845. Andersen was celebrated throughout Europe, although in Denmark itself there was still some resistance to his pretensions. In June 1847 he paid his first visit to England and enjoyed a triumphal social success; when he left, Charles Dickens saw him off from Ramsgate pier. After this Andersen continued to publish much; he still desired to excel as a novelist and a dramatist, which he could not do, and he still disdained the enchanting *Fairy Tales*, in the composition of which his unique genius lay. Nevertheless, he continued to write them, and in 1847 and 1848 two fresh volumes appeared. After a long silence Andersen published in 1857 another romance, *To be or not to be*. In 1863, after a very interesting journey, he issued one of the best of his travel-books, *In Spain*. His *Fairy Tales* continued to appear, in instalments, until 1872, when, at Christmas, the last stories were published. In the spring of that year Andersen had an awkward accident, falling out of bed and severely hurting himself. He was never again quite well, but he lived till Aug. 4, 1875, when he died very peacefully in the house called Rolighed, near Copenhagen.

BIBLIOGRAPHY.—Collected editions of Andersen's works were published in Copenhagen in 33 vols. (1854-79) and in 15 vols. (1876-80). The fairy tales were translated into nearly every European language, and the English editions are very numerous. For his life, see his autobiography, *The Story of My Life* (1855; Eng. trans., 1871), and R. N. Bain, *Hans Christian Andersen, a Biography* (1895). (E. G.)

ANDERSEN, HANS NIELS (1852-), Danish ship-owner and merchant, was born at Nakskov in poor circumstances.

He went to sea and in 1884, having gained experience by trading with the East, he founded the business of Andersen and Co., at Bangkok, opening in 1894 a branch house in Copenhagen. In 1897 he established at Copenhagen Det Oestasiatiske Kompagni (The East Asiatic Company) which soon became the largest commercial enterprise in Denmark and one of the few Danish undertakings of world-wide renown. In 1912 at Copenhagen, the company launched the first large motor-ship. Owing to his powers of administration and his extensive connections throughout the world he rendered important services to his country during the World War.

See A. Fraenkel, *Verden med dansk Maal eller Danmark med Verdensmaal* (1916).

ANDERSON, ADAM (1692-1765), Scottish economist, was born in 1692, and died in London on Jan. 10 1765. He was a clerk for 40 years in the South Sea House, where he published a work entitled *Historical and Chronological Deduction of the Origin of Commerce from the Earliest Accounts to the Present Time, containing a History of the Great Commercial Interests of the British Empire* (1762).

ANDERSON, ALEXANDER (c. 1582-1620?), Scottish mathematician, was selected by the executors of Franciscus Vieta to revise and edit his manuscript works.

ANDERSON, ALEXANDER (1775-1870), pioneer American wood engraver, was born in New York city on April 21, 1775, the son of a printer. At the age of 12 he made his first attempts at engraving without instruction by observing the work of jewelers and other artisans. Among his earliest efforts were copies of anatomical figures in medical works cut with a pocket-knife in plates made by rolling out pennies. In 1789, in compliance with his father's desire, he began the study of medicine and continued until he graduated at the medical department of Columbia college in 1796. But throughout this period he maintained an active interest in engraving. In 1793, upon seeing wood engravings by Thomas Bewick (*q.v.*), he obtained boxwood blocks, designed his own tools, and produced the first wood engravings made in the United States. In 1794 he illustrated with wood engravings the book entitled *Looking Glass for the Mind*. Upon the loss of his entire family from yellow fever in 1798, he withdrew from medical practice and devoted himself entirely to engraving. At first he used both metal and wood, but after 1820 he confined his work almost exclusively to wood engravings. He illustrated numerous books, chiefly after English originals, and produced during his long life an enormous volume of work. At the age of 93 he cut a series of pictures for Barker's *Historical Collection of New Jersey*. He was also a skilled miniature painter and executed numerous portraits. Among his most widely known productions are the illustrations for Webster's *Elementary Spelling Book*; engravings for Shakespeare's plays; Holbein's *Dance of Death*, published as *Emblems of Mortality*, and some 300 cuts for Bewick's *Quadrupeds*. Entirely self-taught, he became the "father of wood engraving in the United States." He died in Jersey City, N.J., on Jan. 18, 1870.

See B. J. Lossing, *Memorial Address on Alexander Anderson* (1872), and F. M. Burr, *Life and Works of Alexander Anderson* (1893).

ANDERSON, SIR EDMUND (1530-1605), English lawyer, descended from a Scottish family settled in Lincolnshire, was born in 1530 at Flixborough or Broughton in that county. He took part in all the leading state trials which agitated England during the latter years of Elizabeth's reign. Though a great lawyer and thoroughly impartial in civil cases, he was notorious for his excessive severity and harshness when presiding over the trials of catholics and nonconformists; especially in those of Sir John Perrot, Sir Walter Raleigh, and John Udall the puritan minister. Anderson was also one of the commissioners appointed to try Mary queen of Scots in 1586. He died on Aug. 1, 1605, at Eyworth, Bedfordshire.

ANDERSON, ELIZABETH GARRETT (1836-1917), English physician, and pioneer in the professional education of Englishwomen, daughter of Newson Garrett, of Aldeburgh, Suffolk. She was born in 1836, and was educated at home and at a private school. In 1860 she resolved to study medicine, an un-

heard-of procedure for a woman in those days, and one which was regarded by old-fashioned people as almost indecent. Miss Garrett managed to obtain some more or less irregular instruction at the Middlesex hospital, London, but was refused admission as a full student there and at many other schools to which she applied. Finally she studied anatomy privately at the London hospital, as well as with some of the professors at St. Andrews University, and at the Edinburgh Extra-Mural school. She had no less difficulty in gaining a qualifying diploma to practise medicine. London University, the Royal Colleges of Physicians and Surgeons and many other examining bodies refused to admit her to their examinations; but in the end the Society of Apothecaries, London, allowed her to enter for the License of Apothecaries' Hall, which she obtained in 1865. In 1866 she was appointed general medical attendant to St. Mary's dispensary, a London institution started to enable poor women to obtain medical help from qualified practitioners of their own sex.

The dispensary soon developed into the New Hospital for Women, and there she worked for more than 20 years. In 1870 she obtained the Paris degree of M.D. In 1871 she married J. G. S. Anderson (d. 1907), a London shipowner, but did not give up practice. She worked steadily at the development of the New Hospital, and also from 1874 at the creation of a complete school of medicine for women in London. London University admitted women to the medical degrees from 1877 onwards. Both institutions have since been suitably housed and equipped, the New Hospital, now the Elizabeth Garrett Anderson Hospital, being worked entirely by medical women, and the schools (in Hunter street, W.C.). In 1897 E. Garrett Anderson was elected president of the East Anglian branch of the British Medical Association. In 1908 she was elected (the first woman) mayor of Aldeburgh. The movement for the admission of women to the medical profession, of which she was the indefatigable pioneer in England, has extended to every civilized country. She died at Aldeburgh, Suffolk, Dec. 17 1917. Her son, Sir Alan Garrett Anderson (b. 1877), shipowner, has been a director of the Bank of England and vice-president of the International Chamber of Commerce. Her daughter, Dr. Louisa Garrett Anderson (b. 1873), continued her mother's work for the advancement of women. She took an active part in the suffrage movement. During the war she was joint organizer of the Women's Hospital Corps and (1915-18) chief surgeon of the military hospital at Endell street.

There is an excellent account of Mrs. Garrett Anderson's early struggles to secure a place in the medical profession in Barbara Stephen's *Emily Davies and Girton College* (1927), in which many of Miss Garrett's letters are given. But the most important source is her sister Dame Millicent Fawcett's autobiography, *What I remember* (1924).

ANDERSON, JAMES (1662-1728), Scottish genealogist, antiquary and historian, was born at Edinburgh on Aug. 5, 1662. Just before the union the Scottish parliament commissioned him to prepare for publication what remained of the public records of the kingdom. The work was not completed at his death in 1728. The book was published posthumously in 1739, edited by Thomas Ruddiman, under the title *Selectus Diplomatum et Numismatum Scotiae Thesaurus*. Soon after his death, the numerous plates, engraved by Sturt, were sold for £530. These plates are now lost and the book has become exceedingly scarce. Anderson died on April 3, 1728.

ANDERSON, JOHN (1726-1796), Scottish natural philosopher, born at Roseneath, Dumbartonshire, was a professor of natural philosophy in the University of Glasgow. He devoted himself particularly to the application of science to industry, instituting courses of lectures intended especially for artisans, and he bequeathed his property for the foundation of Anderson's College, now merged in the Glasgow and West of Scotland Technical College. He died in Glasgow on Jan. 13 1796. His *Institutes of Physics*, published in 1786, went through five editions in ten years.

ANDERSON, MARY (1859-), American actress, was born in Sacramento (Calif.), on July 28, 1859. Her father, an

officer in the Confederate service in the Civil War died in 1863. She was educated in various Roman Catholic institutions, and at the age of 15, with the advice of Charlotte Cushman, began to study for the stage, making her first appearance, at the age of 16, in Louisville (Ky.) as Juliet, in 1875. Her remarkable beauty created an immediate success, and she played in all the large cities of the United States with increasing popularity. Between 1883 and 1889 she had several seasons in London, and was the Rosalind in the performance of *As You Like It* which opened the Shakespeare Memorial theatre at Stratford-on-Avon. Among her chief parts were Galatea (in W. S. Gilbert's *Pygmalion and Galatea*), Clarice (in his *Comedy and Tragedy*, written for her), Hermione, Perdita, Lady Macbeth and Ion (in Noon Talfourd's *Ion*). In 1889 she retired from the stage and in 1890 married Antonio de Navarro, and settled in England.

See William Winter's *Stage Life of Mary Anderson* (1886), and her own *A Few Memories* (1896).

ANDERSON, RICHARD HENRY (1821-1879), American soldier, was born in South Carolina on Oct. 7, 1821. He graduated at West Point in 1842, and won the brevet of first lieutenant in the Mexican War, becoming first lieutenant in 1848 and captain in 1855, and took part in the following year in the Kansas troubles. At the outbreak of the Civil War in 1861 he entered the Confederate service as a brigadier general, being promoted major general in August 1862 and lieutenant general in May 1864. Except for a few months spent with the army under Bragg in 1862, Anderson's service was wholly in the Army of Northern Virginia. Under Lee and Longstreet he served as a divisional commander in nearly every battle from 1862 to 1864, winning special distinction at Chancellorsville and Gettysburg. When Longstreet was wounded at the battle of the Wilderness, Anderson succeeded him in command of the 1st corps, which he led thereafter. His services at the battle of Spottsylvania (*q.v.*) were most important. He remained with the army as a corps commander to the close of the war, after which he retired into private life. He died at Beaufort (S.C.), on June 26, 1879.

ANDERSON, ROBERT (1750-1830), Scottish author and critic, was born at Carnwath, Lanarkshire, Jan. 7 1750, and died at Edinburgh Feb. 20 1830. His principal work was his edition of *The Works of the British Poets, with Prefaces Biographical and Critical* (1792-1807).

ANDERSON, SIR ROBERT ROWAND (1834-1921), British architect, was born at Forres in 1834, the son of a solicitor. He died in Edinburgh on June 1 1921. He was educated at Edinburgh and entered the Royal Engineers, where he received his first training as a draughtsman. His first important work was his successful design for the Edinburgh Medical Schools (1875), and this was followed by a succession of important commissions, including the Conservative club, Edinburgh (1883), the dome of Edinburgh University (1886) and the Scottish National Portrait Gallery (1886-88). He also successfully carried out a series of restorations of Scottish cathedrals, including those of Dunblane cathedral, Paisley abbey, Culross abbey and the interior of Dunfermline abbey. In 1901 he was selected to superintend the alterations which were being carried out at Balmoral Castle; in 1902 he was knighted.

ANDERSON, SHERWOOD (1876-), American author, was born in Camden, O., Sept. 13 1876. His family was poor and his education meagre. After trying various occupations he went to Chicago, where he worked with an advertising agency. His first novel was *Windy McPherson's Son* (1916). In 1921 he was awarded the Dial prize of \$2,000. He has since published several novels, *Marching Men* (1917), *Poor White* (1920), *Many Marriages* (1922) and *Dark Laughter* (1925); short story collections, *Winesburg, Ohio* (1919), *The Triumph of the Egg* (1921) and *Horses and Men* (1923); a book of Whitmanesque verse, *Mid-American Chants* (1918); the autobiographical *Tar—A Mid-West Childhood* (1926) and *A Story Teller's Story* (1924); and *Sherwood Anderson's Notebook* (1926). After devoting himself for a number of years solely to creative writing he bought several country papers in Virginia and became an editor.

Mr. Anderson's fiction, psychological in interest and sombre

in tone, is striking as an attempt to express the evolution and inarticulate longings of industrial America.

BIBLIOGRAPHY.—See biographical and critical articles by Paul Rosenfeld and R. M. Lovett in the *Dial*, Jan. 1922, and "Sherwood Anderson, Corn-Fed Mystic, Historian of the Middle Age of Man," in Harry Hansen's *Mid-West Portraits* (1923).

ANDERSON, a city in the north-western part of South Carolina, U.S.A.; the county seat of Anderson county. It is on four transcontinental highways, and is served by the Blue Ridge, the Charleston and Western Carolina, and the Piedmont and Northern (electric) railways. Between 1900 and 1910 the population increased from 5,498 to 10,570, and in 1930 it was 14,383. Anderson is the centre of important cotton manufactures. Hydro-electric power is available in practically unlimited amounts. In the city and county there are 20 textile plants, representing an investment of \$25,000,000; with an aggregate of about 700,000 spindles and 15,000 looms; manufacturing print cloths, sheets, outing flannels, dress goods, pyjama checks, lawns, ducks, shirtings, drills, twills, fine combed and coarse yarns. The city has in addition 50 or 60 diversified manufacturing plants.

Anderson was settled in 1827. Anderson college for women, a Baptist institution, was established in 1910. About 16m. N.W. is Clemson agricultural college, on the Fort Hill homestead of John C. Calhoun, which, with other property, was bequeathed to the State for the purpose by Thomas G. Clemson (1807-88), the husband of Calhoun's daughter, Anna Maria. The college was opened in 1893; in 1926-27 it had an enrollment of 1,180. The students live in barracks, under military discipline, and wear a uniform. An infantry unit of the Reserve Officers' Training Corps is maintained by the war department.

ANDERSON, a city of Indiana, U.S.A., on the west fork of the White river, about 38 m. N.E. of Indianapolis, in a rich wheat and corn-producing region; the county seat of Madison county. It is served by the Big Four and the Pennsylvania railways, by the Central Indiana (for freight only) and by the Union Traction Company of Indiana (electric). The population (95% native white) was 29,767 in 1920; in 1930, 39,804.

Its importance as a manufacturing centre dates from the discovery of natural gas in the vicinity in 1887. In 1927 it had about 80 factories, manufacturing 140 different products, valued at \$74,059,309. The principal manufactures are automobile generators, starters and horns; playground equipment; corrugated boxes and shipping cartons; nails, wire, files, shovels, wire fencing, floor tile, asphalt roofing, stoves, oil engines, bed and auto-seat springs; silicate of soda; house dresses, aprons and lodge regalia. Large quantities of religious literature are issued by a publishing company. The property valuation is \$33,290,275. Over 9,000 families own their homes. Anderson was founded in 1812 on the site of an Indian village. It was incorporated in 1865.

ANDERSONVILLE, a village of Sumter county, Georgia, U.S.A., on the Central of Georgia railway, about 60m. S.W. of Macon. The population in 1930 was 231. From Nov. 1863 until the close of the Civil War a Confederate military prison was maintained in an open stockade of 26½ac. near the village. The sufferings of the prisoners—from congestion, insufficient food, exposure, pollution of the water supply, and disease—were terrible. Of the 49,485 prisoners received during the war, about 13,000 died. After the war the superintendent, Henry Wirz, was tried by a court-martial and hanged (Nov. 10, 1865). The prisoners' burial ground was made a national cemetery. It contains 13,737 graves, of which 1,040 are marked "unknown."

There is an impartial account of the Andersonville prison in James F. Rhodes, *History of the United States* (1904), vol. v. The partisan accounts are numerous; see, for instance, A. C. Hamlin, *Martyria*; or, *Andersonville Prison* (Boston, 1866); and R. R. Stevenson, *The Southern Side*; or *Andersonville Prison* (Baltimore, 1876).

ANDES, the name applied to the great mountain system which extends the full length of the western part of South America. The origin of the name is obscure. It has been suggested that it is derived from *anti*, the *Quechua* word for east, a name applied by the *Quechua* Indians to the range east of Cuzco. Other suggested origins of the name are the *Quechua* words *antasuya*, region of metal, or *anta*, copper. The term "Cordillera of the

Andes" is sometimes erroneously used as a name for the whole Andean system, and in South American nomenclature is often applied to the most important range of a given section of the system. From its original form, "Las Cordilleras de los Andes," a term applied by the Spanish conquerors to the series of parallel ranges of which the Andes appeared to be composed, is derived the present widespread use of the word "cordillera," meaning an extensive mountain range or system of ranges.

The Andes are narrowest at the southern end and broadest in the central or Bolivian section and at their northern end, where they divide into four distinct ranges. In Tierra del Fuego their trend is nearly east and west; on the mainland the trend is north and south as far north as Lat. 18° S., where, in one of its two broadest sections, the system turns westward to form an almost semi-circular curve convex to the west and follows the configuration of the west coast as far north as southern Colombia. There it spreads out into three distinct ranges, the easternmost of which again divides into two ranges, one of which forms the northern section of the Venezuela-Colombia boundary while the other crosses the boundary south of Lake Maracaibo and extends north-eastward toward the Caribbean sea.

The Patagonian Andes.—Until recently the dominating feature of the entire Andean system was pictured as a great mountain barrier, with a well-defined crest line of lofty peaks which coincided with the water-divide between the Pacific and Atlantic drainage systems, and effectively separated them from each other. As late as 1881, when the Governments of Chile and the Argentine republic signed a treaty in which their common boundary was defined, they described it as following the highest crest of the Andes, which formed the water-divide between the Atlantic and Pacific oceans. When the demarcation of this boundary was undertaken it was found that throughout the greater part of the cordillera the topography did not correspond to the conception of it on which the treaty was based. South of lat. 38° S. the Andes were found to be, not a simple ridge, but a broad zone, from 25 to 40m. wide, of mountain chains and narrow valleys. The higher summits shift back and forth from one chain to another and do not, except in a general way, mark the water-divide. These summits rise above a broad base, represented by high valleys and broad passes, to an average elevation of about 6,500 feet. Few are lower than this average altitude, and only individual peaks exceed

AFTER AN ENGRAVING FROM A CONFEDERATE PHOTOGRAPH IN "MARTYRIA," 1866

ANDERSONVILLE PRISON WITH THE QUAGMIRE AND CROWDS OF HUTS AND MEN BEYOND. OWING TO THE TERRIBLE CONDITIONS PREVAILING THERE 13,000 OF THE 49,000 PRISONERS ADMITTED DURING THE CIVIL WAR DIED OF HUNGER, EXPOSURE AND DISEASE

7,500 feet. Those which have a fairly uniform altitude have been carved by erosion from the older Andean rocks of the plateau-like base. The higher peaks are volcanic cones built up on the plateau. The eastern side of this part of the Andes is divided into two sections—a northern from Lake Aluminé to Lake Nahuel Huapi, and a southern from Lake Nahuel Huapi southward, which includes the island of Tierra del Fuego. Both sections are characterized by a succession of glacier-fed lakes which stretch back like fiords into the heart of the cordillera, and by valleys cut from west to east across the Patagonian tableland through which, at one time, the lakes drained toward the Atlantic.

In the northern section high transverse ridges separate the lake basins and more or less effectively obstruct passage from one to another. These ridges connect the mountain zone with the Patagonian tableland, and all but one of the streams of this section rise in the westernmost range and flow eastward to the Colloncura and Limay rivers. Lake Lacar now discharges across the western range to the Chilean lake region, but there is evidence that it, too, once drained to the Atlantic.

In the southern section the tableland is separated from the cordillera by a longitudinal depression which marks the line of contact between the folded cordillera and the flat tableland and extends southward from the low pass between Lake Nahuel Huapi and Lake Bariloche and is continued beyond the mainland by the Canal Ancho of the Straits of Magellan, Useless bay, and White-side and Admiralty sounds. The continuity of this depression has, however, been frequently exaggerated. It is really divided into several compartments by masses of different kinds of rocks and by granite ridges. Between Lake Argentina and Lake Buenos Aires it is interrupted by the tableland which rises to a height of 5,000ft. and butts against the cordillera. Similarly between Lake Buenos Aires and Lake General Paz there is no great difference in level between the tableland and the depression.

Most of the lake basins here, as well as in the northern section, are continued eastward across the Patagonian tableland as distinct valleys. This is the case even in the submerged southern end of the depression, where the east end of the Straits is a submerged valley on the axis of Otway Water and Useless bay and is continued eastward across northern Tierra del Fuego by the depression which ends in the Bay of San Sebastian. The valleys are now, however, with few exceptions, dead valleys, for the drainage is mostly west to the Pacific by way of narrow canyons in the cordillera and the interoceanic water-divide follows the terminal moraines of the old glaciers which confine the lakes on the east.

On the Pacific side of the cordillera a great longitudinal plain extends from the Chacabuco range, by which the basin of the Aconcagua river is enclosed on the south, southward to the Gulf of Ancud. The northern part of this region is narrow and irregular and is cut by ridges into small, almost completely separated valleys, and interrupted by isolated hills. At about lat. 36° S. it widens out to a width of 20 to 40 miles. A line of recent volcanoes begins a little south of Santiago and is alined on the cordillera to about 35° S. lat., where it gradually departs from the cordillera until in the south it stands well out in the central plain and forms a less continuous but higher chain west of the cordillera proper. The northern part of the plain is filled with recent geological deposits and forms the fertile "Vale of Chile." South of lat. 39° S. it is sown with glacial lakes or depressions formerly occupied by lakes. Not only because of the greater precipitation on the west side of the cordillera in the belt of the westerly winds south of lat. 39° S., but also because of the great condensation of moisture caused by the line of volcanoes in front of the cordillera, the glaciers of the Glacial period advanced much farther from the water-divide on the western slope than on the eastern, with the result that the glacial lakes on the Chilean side of the cordillera are at a much lower level than those on the Argentine side, and part of them, as, for instance, Ranco and Lanquihue, lie completely separated from the cordillera.

The cordillera of Patagonia is divided into a series of massifs separated by longitudinal and transverse depressions. Some of these depressions cut completely through the cordillera and are occupied by rivers which drain lakes on the Argentine side, or by fiords which extend through to the Argentine side. Between 41° and 46° S. lat. the altitude of these massifs is from 6,500 to 8,000ft., only Troncador (11,000ft.) attaining a higher altitude. Between 46° and 50° the cordillera reaches altitudes of from 10,000 to 13,000 feet. It is lower and broken up between Smith channel and the Straits of Magellan, but again rises to more than 6,500ft. on Tierra del Fuego.

South Chilean Andes.—Northward from lat. 39° S. to lat. 30° S. the character of the Andes is greatly simplified. It consists of a double line of crests, the westernmost of which carries

the Argentine-Chile boundary. The high valleys between the crests are at an altitude of from 10,000 to 13,000 feet. The passes to the east and west in the northern part are between 13,000 and 15,000ft. in altitude. South of lat. 31° S. they are somewhat lower. Isolated summits rise from 5,000 to 7,000ft. above the high valleys, and between 32° and 34° S. lat. include three of the highest peaks of the Andes: Mecedario (21,870ft.), Aconcagua (22,830ft.), Tupungato (21,810ft.). The interior valleys have a direction slightly oblique to the general trend of the cordillera and corresponding to the direction of the folds. The whole section has effective drainage of normal type. The water-divide which the boundary follows shifts back and forth from one ridge to another, and the boundary pillars, which are located, in general, on high passes between headwaters, follow a tortuous line. Eruptions from the chain of recent volcanoes which appears a little south of the latitude of Santiago and extends southward on the Pacific side of the main axis of the cordillera to the Gulf of Ancud have greatly complicated the topography of the cordillera by filling up high valleys or damming up lakes.

East of the cordillera in this section a continuous depression extends northward from the Mendoza river for more than 160m. between the cordillera and the pre-cordillera (a series of short ranges reaching out into the Argentine plain and formed by a north-south alinement of narrow crests of Silurian limestones between sandstones and metamorphosed Devonian schists). The pre-cordillera continues south of the Mendoza river to about latitude 36° S. It attains heights of 13,000ft. in the latitude of San Juan and 11,000 on the Paramillo plateau above Mendoza. In spite of their narrow width the Andes in this section offer serious obstacles to movement from one side to the other because of their elevation and covering of snow. They have no mineral wealth and the few routes across them, which include the Transandine railway between Santiago and Mendoza, are solely for the purpose of crossing the cordillera and not for exploiting its subsoil. The high valleys furnish some summer pasture and the rivers and lakes afford water for irrigation. Settlements lie not in the mountains but on their border, and the location of the more important of those on the Argentine side has been influenced by the position of the most practicable passes, since it is to cattle and goods trade with Chile that they owe their origin and growth.

The Puna de Atacama.—North of lat. 30° S. the Andes again lose their simple character. The mountain belt widens and long extensions of it reach out south-eastward to the Argentine plain, enclosing in the depressions between them long embayments of the plain. At about the 28th parallel the main range divides into a western and an eastern range, with a belt of very high and extremely cold and desolate country between them (called the Puna de Atacama), made up of mountain chains, isolated peaks, and basins of salt deposits known as salars, arranged along dominating north-south lines. The average height of the basin floors of the Puna is between 11,000 and 13,000ft., with the interior peaks and ridges rising only from 1,000 to 5,000ft. higher. The range which forms the western border of the Puna is known as the Cordillera de Los Andes or Maritime cordillera and consists chiefly of a line of high volcanoes with lava flows between them. The passes in the Maritime cordillera average about 15,000ft. while the peaks reach 20,000 to 23,000 feet. In the range which forms the eastern border of the Puna the passes are from 16,500 to 17,000ft. high, but the peaks average only from 18,000 to 20,000 feet. In contrast with the western cordillera in which the volcanic cones are high and have been built up on a lower basement of lava, the cones of the eastern cordillera are low and have been built up on broad beds of lava. West of the western cordillera is a line of depressions between 3,000 and 4,000ft. lower than the average level of the Puna and enclosed on the west by the Cordillera Domeyko which contains a number of salars, among them the Salar de Atacama and the Salar de Punta Negra.

East of the eastern border of the Puna, the Andes of the Argentine provinces of Jujuy, Salta and Tucuman form a broad belt of ridges oriented from north to south and separated by deep depressions. Their altitudes diminish as they extend eastward into the Argentine plains, and their summits, as well as those of

the secondary ranges along the main mountains, exhibit an older aspect than their ravined borders. The tops and high upper slopes are covered with grass. The steep headwater slopes and narrow declivities of the ravines, cut into them as the result of recent uplift, are youthful features in contrast to the lawn-like high-level slopes which they are gradually invading.

The Central Andes.—The northern limit of the Puna de Atacama is a transverse range of high snow-capped peaks and ridges at about the 23rd parallel, which separates it from the drainage basin of the Salar de Uyuni. The high plateau continues northward as the *altiplano* or *altiplanicie* of Bolivia. This *altiplano* has no outlet to the sea, and is therefore one of the world's great basins of interior drainage. It is about 500m. long by 100m. wide, and slopes gently from a little over 12,500ft. at Lake Titicaca to slightly more than 12,000ft. at Lake Poopo, and a little lower at the Salar de Uyuni. It differs from most interior drainage basins in that it contains a large body of fresh water (Lake Titicaca) and an important river drainage (the Desaguadero river). Lake Titicaca is the highest large body of navigable water in the world and has a length of about 125 miles. It owes its existence to a deep tectonic depression in close proximity to a high snow-capped mountain range (the Cordillera Real) that keeps it supplied with water. Farther south the *altiplano* becomes more and more like other interior semi-deserts, for the windward mountains become lower, so that they condense less moisture, and broader, so that the precipitation is more widely distributed. As it flows southward, the Desaguadero river, the outlet of Lake Titicaca, grows smaller and smaller until Lake Poopo, into which it empties, is a shallow pond with only a small overflow to the nearby salt lake or marsh called Coipasa. The *altiplano* lies between two great table-lands with superimposed peaks and ranges. Its eastern edge is particularly well-defined by the sharp rise and straight form of the eastern cordillera. The western edge is less clearly defined because of the volcanic debris that has encroached upon it from the western or Maritime cordillera, forming hilly districts of irregular outline. Between the Salar de Coipasa and the Salar de Uyuni, the *altiplano* is divided into two interior drainage basins by a line of volcanoes and hills which extend from the western cordillera nearly across to the eastern. North of Lake Titicaca the bordering scarps converge in the Nudo de Vilcanota at about 14° S. Lat., and enclose the *altiplano* on the north.

The western cordillera descends by relatively smooth slopes to the coastal deserts of Tarapacá and Atacama, famous for their nitrate deposits, and the desert region of southern Peru. In the rare cases in which its streams permanently reach the piedmont, they furnish water to small but important fields of vegetables and alfalfa. Viewed from the west, the cordillera presents, for long distances a strikingly even skyline, generally the line along which the uplifted peneplane has been warped up to form the highlands, broken only by the summits of the highest volcanoes which stand back toward the *altiplano* or, in places, by volcanoes like El Misti and Tacora, which rise on the western edge of the cordillera. The most recent of these volcanoes, such as El Misti, Tacora and Sajama, are symmetrical cones surmounted by craters; but the greater number are much older than these, and have more or less lost their original form by erosion.

The eastern cordillera, where it borders the *altiplano*, falls into two sections of quite different physiographic aspect. In the northern section the character of the uplifted peneplane has been almost completely destroyed because the concentration of the rainfall in a narrow belt in this region and the relatively steep gradient of the rivers have combined to enable the streams to cut the old surface to pieces, leaving only the lofty snow-clad Cordillera Real standing on a narrow base. The Cordillera Real is a central core of resistant rocks whose superior hardness and greater initial elevation have preserved it from the effects of great denudation recognizable all around it. The Cordillera Real is cut between the Nevado de Illimani and the Nevado de Quimsa Cruz by the chasm of the La Paz river, a tributary of the Madeira river of the Amazon system, which, by virtue of the enormous condensation of moisture on the eastward slope of the eastern cordillera, has been able to break through this great barrier to the *altiplano*; but the

axis of the Cordillera Real extends southward across the La Paz valley through the Nevados de Araca, Quimsa Cruz and Vera Cruz, forming a line of heights as definite in trend and structure as the Cordillera Real and continuing its features southward nearly 50 miles.

Northward from Lake Titicaca the western range turns northward, while the eastern range, which has already in the Cordillera Real taken a north-westerly trend, turns still further to the west and cuts off the *altiplano* by merging with the western range in a rough mountain mass known as the Nudo de Vilcanota. The Eastern Cordillera, here called the Cordillera de Carabaya, is a lofty snow-capped range separated from the Cordillera Real by a narrow and relatively low divide between the headwaters of the Mapiiri river (a tributary of the Beni) and the Lake Titicaca drainage. On the west flank of the Cordillera de Carabaya is a group of glacial lakes in narrow depressions between the spurs of the range. There is no record of any soundings having been made in them, but from descriptions of their deep colouring and the character of the depressions in which they lie, they appear to be among the deepest of the high glacial-fed lakes of the Andes. The Cordillera de Carabaya lowers very rapidly to the north-east to the Amazon plain, and larger tributaries of the Beni cut directly across the lines of low ranges which front it on the east. Farther north, however, the valleys of the tributaries of the Madre de Dios have a longitudinal trend and have cut deep troughs oriented from south-east to north-west like the ridges which separate them.

The Peruvian Plateau.—The Andes of Peru, north from the Nudo de Vilcanota, are usually described as three distinct ranges which merge in the Nudo de Pasco and then continue north again as separate ranges. Recent studies show that they are a single broad plateau from 13,000 to 15,000 ft. high, on which narrow cordilleras rise to 18,000 and 21,000 feet; and that the *nudos* or knots are only gigantic erosion remnants. The Amazon tributaries have cut deep gorges almost to the western edge of the plateau, while the numerous streams of the arid Pacific slope are short and, with the exception of the Rimac and Santa rivers, carry little water as far as the ocean.

The Andes are divided into three natural regions—the *montaña*, the eastern slopes of the Amazon forest; the *sierra*, the temperate regions of the slopes and secondary valleys of the plateau; and the *puna*, cold, monotonous regions in the cordilleras, of vast extent at altitudes of from 10,000 to 15,000 feet. In isolated sections above the *puna* are areas known as *jalcas* which resemble the *paramos* of Colombia and Ecuador. They are covered with a dense, steppe-like vegetation that varies but little from season to season. North-west of the Nudo de Vilcanota is a narrow trough sunk below the level of the plateau to an elevation of 11,000ft., known as the Cuzco valley, from the City of Cuzco which lies at its upper end, on the site of the ancient Inca capital. The trough is 19m. long and is divided into three basins of flat-lying land arranged like the links of a chain. Its bordering rims have an average altitude of 13,500ft., with peaks exceeding 14,500ft., and are cut through in many places by streams leading to the Urubamba and Apurimac rivers. The valley itself is drained by the Huantany river which flows through the chain of basins and joins the Urubamba through a broad pass in the mountain wall. The most broken section of the Peruvian Andes is between Abancay and Huancayo where the Apurimac, Pachachaca, Pampas and Mantaro rivers have cut deep gorges 6,000ft. and more below the surface of the *puna*. The zone of the interoceanic water-divide is here a gently undulating plateau, with lakes of glacial origin which the recently eroded valleys have not yet reached. The many secondary valleys, such as those of Ayacucho and Lircay, have long been centres of grain cultivation.

From the Huancayo to Cerro de Pasco the plateau is chiefly the basin of the upper Mantaro river. In the Cordillera de Huarochiri through which the Central railway from Lima to Oroya cuts, at an altitude of nearly 16,000ft., on red porphyritic sandstones between crests of dark andesites, the divide rises to elevations of over 17,000 feet. On the western slopes of the Cordillera de Huarochiri are many glacial cirques, and immediately north of the route of the Central railway as it enters the cordillera is a great

cluster of lakes at different levels, still fed by glaciers, which drain into the Rimac river close to the edge of the plateau. East of the crest a network of glaciated valleys with many lakes descends in steps to the Mantaro river. East of the Mantaro a little known range, whose snow-capped summits approach 16,500ft., cuts off the horizon north-east of the plain of Jauja. Its altitude diminishes to the north-west, and north of Tarma no longer carries permanent snow.

The Mantaro river rises at an altitude of about 15,000ft., near the mining town of Cerro de Pasco, in a marshy plain with many shallow lakes. Most of these are only small ponds, but Lake Junin, the largest of them, is about 20m. long. A group of partially glacier-fed lakes close to the main divide, of which Lake Punrún (15m. long) is the largest, also drains to the Mantaro river near the outlet of Lake Junin. The Mantaro flows south-eastward in a long limestone gorge to the plains of Jauja and Huancayo. These plains stand at 12,500ft. and 11,600ft. respectively, and together form a depression, 25m. long by 6 to 8m. wide, bordered on both sides by rows of bare hills behind which rise snow-capped ranges. The Mantaro leaves the depression in a deep gorge and swings round in a great bend to the Amazon plain about 80m. below Huancayo. The Cerro de Pasco region, north of the plain of Junin, has been given great importance in descriptions of the Peruvian Andes as a mountain knot in which are merged three distinct cordilleras. In reality it does not exceed the altitude of the *puna* and is only a fragment of the continuous plateau of sandstones and limestones, with occasional crests of andesite, which extends north of the plain of Junin and south between the plains of Junin and Jauja.

From Cerro de Pasco to the Pongo de Manseriche the plateau forms the drainage basin of the Huallaga and the upper Marañón rivers. North-west of Cerro de Pasco the Cordillera de Huayhuash forms the interoceanic divide. The Marañón river flows from a chain of glacier-fed lakes on its north-east flank, while on the same slope, a short distance to the south, are the sources of the Huallaga river. The Huallaga valley is fairly wide as far as the gorge east of Huánuco in which it turns northward toward the Amazon and the valley floors of both the main streams and its tributaries in the plateau are well-irrigated and have a considerable population. Below the Huánuco the Huallaga is a swift-flowing stream, with many rapids and gorges, and flows in a northerly direction through the foothills and low ranges for 180m. before it finally breaks through to the Amazon plain in the gorge or *pongo* of Aguirre, at lat. 6° 30' S. The Marañón flows in a deep trench and has only a sparse population of Indian communities, which occupy the upper basins of its affluents and occasional sugar plantations at the mouth of the larger tributaries or at rare points where the valley widens.

The Cordillera Blanca, north of the Cordillera de Huayhuash has the same south-east to north-west trend as the latter but stands slightly to the west of its axis. These are both lofty snow-capped ranges with elevations that may be classed among the highest of the whole Andean highland, Cerro Carnicero in the Cordillera de Huayhuash being 21,760ft. high, and Cerro Huascarón in the Cordillera Blanca 22,180 feet. The valley of the Santa river (known as the Callejón de Huaylas) which separates the Cordillera Blanca from the Cordillera Negra (so-called because its crests do not exceed 16,500ft. and, therefore, bear no permanent snow) is the most densely populated district of this section of the Andes. The river has its source in Lake Conococha in the high *puna*; flows, with a descent of 6,500ft. in 60m., through a string of lacustrine basins of rich alluvial soil; and carries a large permanent stream through a gorge across the Cordillera Negra to the Pacific ocean.

Ecuador.—North of the Peru-Ecuador boundary the plateau is higher, rising to altitudes of over 10,000ft., but the interoceanic divide continues narrow as far north as lat. 3° S. From there northward to the Nudo de Pasto, in southern Colombia, the Andes appear to be a single broad plateau, the top of which is in places 40m. wide, surmounted by irregularly distributed volcanic masses which rise to elevations from 11,000 to 12,000ft. above the plateau, and divide it into a number of separate basins (*hoyas*)

at an average elevation of from 7,500 to 9,000 feet. It has been the custom to describe this section of the Andes as consisting of two parallel cordilleras (a western cordillera and an eastern cordillera, or Cordillera Real) with a high plateau between them which is divided into separate basins by cross ranges from the main cordilleras. Our present knowledge does not support this description, and it seems to be only the rather general north and

ONE OF THE MANY WAYSIDE SHRINES THAT TOP THE HIGH RIDGES OF THE ANDES

south alinement of some of the outstanding volcanoes on the east and west borders of the basins and, particularly, of the Quito and Latacunga-Riobamba basins themselves, that has given rise to such a characterization. In the interior basins is concentrated the population of the plateau. Their rich volcanic soil and temperate climate had permitted their Indian inhabitants to attain, long before the conquest, a state of civilization far above the savage. They are in the rain-shadow of the mountain masses which enclose them on the east and west, and have, at the most, only moderate rainfall and, in some cases, require irrigation. By contrast, both outer slopes have very heavy rainfall at about the level of the basins and are covered with luxuriant vegetation, while above 10,000 to 11,000ft. they have very heavy rainfall on both sides. These high regions of heavy rainfall are the regions of the *páramos*, cold, desolate areas on both the slopes of the cordilleras and on the cross ranges, with a covering of moss and other bog growths and enshrouded in almost perpetual mist.

The Cuenca basin, in the south, and the Latacunga-Ambato and Riobamba basins, in the central plateau, drain to the Amazon; while the Alausi basin, north of the Cuenca basin, and the Quito and Ibarra basins in the north, drain to the Pacific. The Andes in this section slope steeply to both the Pacific and the Amazon plains. The streams from the basins have, therefore, steep gradients. Because of this and the steady supply of water from the adjoining mountaintop *páramos*, the streams have eroded deep beds and few lakes remain, of which San Pablo, in the Ibarra basin, is the only one of considerable area. Erosion is slight at the parts of the basins farthest from the outlet through the mountains, but deepens rapidly as the outlet is approached. In the case of the Guallabamba river, which drains the Quito basin, the total depth is over 3,000ft., of which 1,200 is a steep-sided canyon.

An essential characteristic of the northern half of the Andes of Ecuador is the volcanoes which not only border the western side of the interior basins, from Chimborazo to the Nudo de Pasto in southern Colombia, and the eastern side from nearly lat. 2° S. to the Equator, but are grouped in many places between the basins and, in places, stand completely in them. They really owe more than half their height to the base of ancient rocks on which they stand, but so impressive are they that even conscientious observers have frequently exaggerated the steepness of their slopes. The principal volcanoes of the more westerly line of volcanoes are Chimborazo (20,700ft.), Canhuairazo (16,784), Quilato (15,715), Iliniza (17,405), Pichincha (15,718), Catacachi (16,292), Cimbab (15,715), Chiles (15,682); of the eastern, Altar (17,729), Tunguragua (16,689), Cotopaxi (19,498), Antisana (18,851), Cayambe (19,062). Sangay (17,470) lies still farther to the east, and Sumaco (12,700), which is believed to be a volcanic cone, lies far out on the eastern slope east of the Cordillera Guacamayo.

The eastern slopes of the Andes of Ecuador are little-known. Recent explorers have described the Amazon lowland as joining the base of the plateau at elevations averaging between 3,600 and 4,000ft., and sloping gently eastward with a descent of 1,000ft. in the first 70 miles. There has been no exploration of the southern part of the lowland. North of the Napo river recent explorations have revealed a number of short ranges and mountain masses of moderate elevation rising above the general level. Among these are the Cordillera Guacamayo and the Cordillera Galeras, with elevations reaching 8,000ft. and 6,000ft. respectively, and the

cone-shaped Sumaco (12,700ft.). Still farther north a short range on the Equator called the Cordillera Lumbaki and two high mountain masses north-west of Sumaco have recently been discovered.

The Cordilleras of Colombia.—In southern Colombia the Andes divide into three separate ranges: the western cordillera, or Cordillera de Choco; the central cordillera, or Cordillera del Quindío; and the eastern cordillera, or Cordillera de Bogotá. The valley of the Magdalena river which separates the eastern cordillera from the central and part, at least, of the Patía and Cauca valley between the central and western cordilleras are not narrow, eroded trenches, but broad tectonic depressions with a deep alluvial cover. The western cordillera forms the coast range of Colombia in the south and, to the north, extends on the east side of the valleys of the San Juan and Atrato rivers to the Caribbean coast. It is the lowest of the cordilleras, with elevations varying, in the southern section, from a little over 5,000ft. on the Pacific railway between Buenaventura and Cali, to 7,200ft. west of Cartago and 10,000ft. west of Popayán, and rising to elevations of 11,000 and 13,000ft. in the west and northwest of the province of Antioquia. The southern 250m. of the depression between the western and central cordilleras is occupied by a series of three broad longitudinal plains. The southernmost is drained by the Patía river to the Pacific ocean, while the northernmost, with a length equal to the combined length of the other two, is the famous Cauca valley and drains to the Magdalena by the Cauca river. The central plain, in which is the city of Popayán, contains the low divide between these two drainage basins. Its elevation (6,000ft.) is 3,000ft. higher than those of the Cauca and Patía plains, and its northern and southern borders are, therefore, deeply trenched. The Cauca plain has many aspects of an old lake basin filled with detritus. The city of Cali stands slightly above the level of the plain on a gently sloping alluvial fan. North of the Cauca plain the Cauca river flows by a series of gorges through a region of hills and valleys between the western and central cordilleras. Its lower plain is bordered by gradually disappearing spurs until it finally merges in the plains of the lower Magdalena river.

The central cordillera is the highest of the cordilleras of Colombia and the shortest, its last spurs disappearing south of the junction of the Cauca river with the Magdalena, 170m. from the Caribbean. It contains the only recent volcanoes in the Colombian Andes. Of these, Tolima (18,400ft.) and Ruiz (18,400ft.) are the most important. At lat. 5° 30' N. the cordillera widens to form the plateau of Antioquia, whose last spurs extend as far as lat. 8° N., where they are lost in the plains of the Magdalena. This plateau appears to be a block of ancient crystalline rocks with intrusions of diorites and diabases divided into two parts by the deep trench of the Porce and Nechi rivers. The groups of highlands on both sides of the Porce river preserve, in their gently broken surfaces, traces of a very ancient cycle of erosion. The larger of these covers an area of about 1,200 sq.m. N. of Medellín and has an average elevation of 8,500ft., with diminishing heights toward the north-east. The other extends south-east of Medellín, and contains the upper valley of the Nare or Negro river. Medellín, the second city of Colombia, occupies an advantageous position in the Porce valley, where it widens out for a distance of about 8m. into a fertile alluvial plain.

The eastern cordillera is somewhat analogous to the Andes of Ecuador in that its most marked characteristic is a series of high intermontane plains or *savannas*, at a nearly uniform elevation of 8,000 to 9,000ft., of which the most important are at the headwaters of the Bogotá, Suarez and Sogamoso rivers on the eastern border of the Magdalena basin. Their subsoil is formed of beds of fine gravels and clays, with some beds of peat, and the majority contain shallow lagoons and bogs which are partly submerged during the rainy season. Most of them have areas in their centres too wet for cultivation, so that the population is grouped about their edges. These high *savannas* were the centre of the pre-colonial Chibcha civilization and now contain a third of the entire population of Colombia. The Savanna de Bogotá is the largest and most densely populated of them, and has only a narrow strip of useless bog land in its centre. Bogotá is built on its eastern edge.

East of Girardot and Honda the cordillera is a series of parallel

ranges, running from south-south-west to north-north-east, of which only the easternmost, the Sierra de Cocuy (17,500ft.), reaches the level of permanent snow. North of the Sogamoso river the ranges have a north-south direction and in the latitude of Bucaramanga are united in a broad block. Farther north the central ranges stop and the western and eastern continue on, diverging toward the north and north-east as the Cordillera de Ocaña, of which the Sierra de Perija forms the boundary between Colombia and Venezuela, west of Lake Maracaibo. North-east of the delta of the Magdalena river, the Sierra Nevada de Santa Marta, a triangular massif with steep slopes to the north and west, rises abruptly from the Caribbean coast to snowy summits 17,000ft. high. It is separated from the Sierra de Perija by the valleys of the Cesar and Rancheria rivers.

A great many lakes exist in the cordillera east of Bogotá and on both sides of the upper Sogamoso, but the *páramos* have usually gentle forms and show traces of a long erosion period. It is, however, only on the high plains and the *páramos* that the streams of the interior now meander. They are rapidly cutting the greater part of their courses and upon leaving the *savannas* they flow through deep canyons. The falls of Tequendama south-west of Bogotá are the most striking example of the manner in which these streams have dissected the borders of the high plains, but the Suarez and Sogamoso rivers exhibit the same characteristics. Tributaries of the Orinoco river have cut through the eastern range to the neighbourhood of the *savannas* at points south of the Sogamoso and Tunja rivers. South of Bogotá the eastern cordillera is narrow. The Páramo de Sumapaz reaches elevations of 14,000ft., and snow remains there throughout most of the year, but farther south the range is much lower. In the Sierra de Perija, which forms its northern extremity, the cordillera narrows to about 16m., and its highest crests do not exceed 8,000 feet.

Venezuela.—The Andes of Venezuela are separated from the eastern cordillera of Colombia by a depression of about 4,600ft. altitude, between the Tachira and Torbes rivers, and extend north-east and east for about 500m., across the northern part of the country. Transverse valleys cut them into three sections, the area and altitude of which decrease from west to east. The westernmost section, from the sources of the Torbes river to the sources of the Tocuyo river is known as the Cordillera de Merida. It is about 160m. long and 30 to 50m. wide. Its snow-capped summits are all above 10,000ft., and in the Sierra de Santo Domingo and the Sierra Nevada de Merida exceed 14,500 feet. In the Andes of Venezuela the coastal sierras have a west to east direction, and are separated from a second line of much lower mountains by a depression in which are the basins of Lake Valencia and the Tuy river. Eastward from Puerto Cabello the range rises steeply from the coast. Its western end is only a little over 5,000ft. high near Nirgua, but it reaches 9,000ft. on the Silla de Caracas north-east of Caracas, and falls to 7,500ft. west of Cape Codera. The Caracas valley, in which is the city of Caracas at an altitude of 2,600ft., is only 6m. from the sea, and is not a part of the central depression. It appears to be, rather, a subsided local block covered with alluvial soil.

East of Cape Codera the Gulf of Barcelona interrupts the mountain zone for a distance of 80 miles. Only a narrow line of sandstones and limestones continues eastward from the interior range along the flat coast. Its altitude lowers rapidly from 4,000ft. to 1,600ft., and it is completely interrupted by the Unari and Aragua rivers, which drain a part of the llanos to the Gulf of Barcelona. The Sierra de Cumana extends for 80m. between the Aragua river and the Gulf of Paria. Its interior is a massif of sandstones and folded limestones which rises to 7,500ft. in the Cerro Turumiquire. The double peninsula of Araya and Paria is a narrow belt of crystalline schists, with an altitude of 1,300ft. west of the town of Carupano and a little over 3,000ft. at its eastern end near the Boca del Dragón, beyond which it is continued as the northern range of Trinidad island.

Geology.—The beds of the Primary series are found in the Andes in a longitudinal zone on the eastern side of the cordillera. They form the eastern part of the plateaus of Bolivia and northern Argentina, where the high anticlinal ranges are of Cambrian

quartzites, while Silurian schists, surrounding the recent granite crests of the Cordillera Real, cut by deep valleys, and overlapped in the synclines by Devonian and Secondary red sandstones, form the base of the series. They are found, also as Silurian sandstones, schists and Devonian sandstones on the eastern side of the Chile-Argentine cordillera as far south as lat. 35° S. and in the pre-cordillera.

The zone of the Secondary beds is of much greater length, Breccias and porphyritic conglomerates are the most common formation, forming almost the whole of the western part of the Andean system. In Peru they are succeeded to the east by gray limestones, which cover the greater part of the plateau. Still farther east, on the Marañón and upper Huallaga rivers, the ridges are of Secondary sandstones above Silurian schists. In Ecuador the Secondary conglomerates of the western side of the plateau rest directly upon the Andean gneisses and mica-schists, of which the eastern part is composed. In Colombia the central cordillera is formed of mica-schists, with almost no trace of sedimentary covering; while, in the eastern cordillera, even on the border of the plains of the Orinoco, the conditions which prevail farther south are completely reversed and the Secondary beds have their greatest development. The importance of the Secondary marine deposits in the Andes, especially in the Jurassic and Cretaceous series, seems to indicate that, during the Secondary period the region of the Andes was a geosyncline inundated by the sea between two continental masses, one of which occupied the place of the present Pacific ocean. The relations between the Andes and the *vorland* to the east is obscured by an enormous development of alluvial forms which partly cover the zone of contact between the lowlands and the cordilleras. It has been suggested that it is a rigid zone against which were exerted the forces to which the folding of the geosynclinal Andes was due.

The beginning of the folding of the Andes dates from the upper Cretaceous and continued during a part, at least, of the Tertiary. Tertiary marine forms are, therefore, lacking in the interior of the cordillera and are known only in eastern Patagonia, on the extreme edge of the cordillera. The Tertiary is represented in the greater part of the Andes by continental deposits without fossils, which furnish no precise information on the age of the folding. North of the Patagonian Andes as far as lat. 4° S. the western ranges contain Jurassic rocks and porphyritic rocks of similar age folded together. Both are of interest, the Jurassic because they are the only marine sediments of that age south of the Equator, the porphyritics because they are the most important evidence we have of volcanic activity in Mesozoic times. North of lat. 4° S. the Jurassic and porphyritic rocks are comparatively rare and the Primary rocks are absent. The majority of geological cross-sections which have been made in the Andes indicate foldings of the simple Jura type rather than the complex type of the Alps. The cross-sections are, however, still comparatively few, and greater complexity may be revealed by further studies.

Evidence of the uplift of the Andes is found not only in the existence of Tertiary and Quaternary marine deposits on the Pacific coast and many examples of uplifted shore-lines, but also in the frequent occurrence throughout the cordillera of surfaces which could only have been formed at an altitude near sea-level. These areas are found even in the more humid parts, where the contrast between them and the deep ravines of the headwater streams which are now invading them is most striking. The peneplane has been most completely conserved, however, in the deserts of the Maritime cordillera of northern Chile and southern Bolivia. In the terracing of the valleys, particularly on the eastern side of the cordillera, there is evidence of a succession of vertical movements, interrupted by periods of rest; while in the coastal terraces all the way from Paita to Antofagasta we find evidence not only of periods of rest but also of at least one subsidence followed by an uplift, which is still in progress at the present time. In fact, along the entire western seaboard the region has suffered enormous disturbances in the past, while the frequent earthquakes that have occurred in recent years in many parts of the coastal region and the cordillera are evidence that these disturbances are still going on. The abrupt transition from high tableland to abyss-

mal ocean depths that is characteristic of the entire coast indicates the remarkably unstable condition of the region. In addition to the general or regional movements of uplift and subsidence, the existence of drop-faulting has been noted throughout the whole length of the cordillera. The upper Magdalena valley, the Cuzco basin, the Iglesia and Calingasta valleys between the cordillera and the pre-cordilleras of the Argentine republic, and the central valleys of Chile have all been thus explained.

The volcanoes of the Andes occur in three notable groups, southern Colombia and northern Ecuador, southern Peru and northern Chile, and the group of central Chile, Neuquen and Patagonia. All types are present, from ancient volcanoes almost completely destroyed by erosion and extinct volcanoes, with or without craters, but still fresh in form, to active volcanoes. They have played an important part in the levelling of the interior basins. Fluid lavas exposed appear only on the Patagonian plateau. Elsewhere the lavas are chiefly of the viscous acidic type and, although accumulated to great depths in many places (as much as 1½ m. deep in the Cordillera de Vilca pampa in southern Peru), have not been removed far from the craters. The volcanic ash, however, has been carried away by erosion in such quantities that they have overcharged the streams and filled depressions and valleys to a great depth.

Climate.—It is not on the Equator but between lat. 15° and 20° S. that the highest temperatures of the Andes are found, and we must go south of the Tropics to find mean annual temperatures comparable to those on the Equator. The abnormal depression of temperatures in the equatorial Andes is due to the heavy rainfall, and it is the lack of rainfall that raises the temperatures to the south. The effect of the higher temperatures of the drier Andes is to elevate the upper limit of agriculture and human occupation. In Colombia the highest agricultural zone is between 6,500 and 11,000 ft., while on the moister portions of the Bolivia *altiplano* agriculture is carried on over 3,000 ft. higher. The rich agricultural basins of Cuzco and Jauja, if they lay at the same elevation in the humid equatorial Andes, would not belong to the agricultural regions at all. The lower limit of the colder agricultural zone is not, however, parallel to the upper limit, and as one leaves the Equator frosts occur at lower and lower levels. As a result, sugar cane, which grows at a level of 6,500 ft. and more in Ecuador and Colombia, does not reach above 3,000 ft. in northern Argentina.

The lower limit of perpetual snow in the tropical Andes is between 15,000 and 16,000 feet. On account of the increasing aridity, it rises rapidly south of the equatorial region to 17,000 ft. on the western ranges of the Peruvian Andes, above Lima, and to 18,000 and 20,000 ft. in the summits which border the Puna de Atacama, to the north-east. South of the Puna de Atacama it lowers again to 18,000 ft. in the Famatina ranges, and to between 14,500 and 16,500 ft. in the ranges of Juan and Mendoza. From these it falls rapidly to 6,500 ft. at lat. 37° S., 5,000 ft. at lat. 40° S., and 2,300 ft. on Tierra del Fuego. In the tropical and subtropical sections of the Andes the present glaciers rarely extend beyond the snow line. South of lat. 40° S., however, they have more extensive fields of supply, and come well down into the valleys. South of lat. 46° S. the ice-fields, though only a shrunken remnant of the ice-fields of the Glacial period, still form a continuous cap over the entire central zone of the cordillera. Throughout the Andes there have been recognized, in front of the present glaciers and in regions to-day free of ice, glacial moraines, cirques, outwash plains and lakes confined behind glacial dams, that are proofs of several periods of extensive Quaternary glaciation.

Mining is an important industry in all of the Andean countries. In Chile and Bolivia it far exceeds all other industries in the value of its products. The most important mineral deposits are those of the younger igneous rocks which include the gold quartz lodes of Colombia, the silver-bearing copper deposits of Peru and Chile, and the tin-silver-bismuth deposits of Bolivia. The copper deposits, which are found in many sections of the Andes, but are particularly abundant in Chile and Peru and, to a lesser degree, in Bolivia, differ greatly in their geological occurrence and characteristics. They occur most frequently as replacements of rock

near intrusions of igneous material. At Portrerillos, Chile, they have replaced the easily soluble limestone. At the Braden mines, near Rancagua, Chile, and the Cuquicamata mines, the copper minerals have filled cracks and openings in less soluble rocks with little or no replacement. In many places, as at Cerro de Pasco, Peru, rich silver ores at the surface give place to copper ores at lower levels. The tin deposits of Bolivia are true fissure veins or disseminations filled by products of igneous intrusives. The only gems occurring in the younger igneous rocks are the emeralds of Colombia. Of the ores which occur mainly in association with the ancient crystalline rocks, gold-bearing and silver-bearing veins in the pre-Cambrian schists, gneisses and granites, in many places in the cordilleras, and iron ore, chiefly magnetite, in Chile, are the most important. Mineral deposits of economic value in the sedimentary rocks are not extensive. Chile, Peru and Colombia have extensive coal deposits, but they are of inferior quality as compared with foreign coals, and except in Chile, are so inaccessible that they have been worked but little, except for local use. Petroleum resources have been studied intensively, and indications of oil-bearing strata have been reported on the eastern border of the Andes all the way from Venezuela to Tierra del Fuego. The areas which are at present yielding the most valuable flows are the Maracaibo basin, in Venezuela, the basin of the Sogamoso river on the western border of the eastern cordillera of Colombia, and the coastal region of northern Peru at Talara. Of the placer minerals, gold is the most important, and the extensive placer operations have of recent years been mainly confined to Colombia, particularly in the Choco district, where they yield considerable platinum.

From the standpoint of human occupation, the Andes are divided into three sections—an unpopulated section extending north to the Puna de Atacama; an arid central section from the Puna de Atacama to northern Peru, where mining is the chief industry; and a humid northern section, of which the chief industry is agriculture. The southernmost section has little mineral or agricultural resources, and the population is, therefore, not in the mountain zone but on its borders; concentrated in irrigated districts on the eastern side and more uniformly distributed in the central valleys of Chile on the western side. In the Puna de Atacama there is a sparse population of shepherds, and a still smaller element engaged in collecting salt from the salars for sale in the settlements on the mountain border. From there north to the Caribbean sea, however, the greater part of the population of the west coast and Caribbean republics, and, with few exceptions, the chief cities, are on the plateau. This populated section of the Andes contains a third of the whole population of South America. It consists of two sections of distinctly different character. The southern and more arid section is a region in which mining is the dominant industry, and practically the only source of export. All other industries are maintained for the purpose of supplying it with food, clothing and means of transportation. Railways which penetrate into the cordillera from the Pacific coast are constructed solely to transport the products of the mines to the nearest ports. The influence of the mining industry, since the mining districts are mainly on the high *páramos*, has combined with climatic conditions to elevate the altitudinal limits of human habitation to levels which are among the highest in the world. Since before the conquest the characteristic of this section of the Andes has been the establishment of small agricultural communities on the alluvial floors of high, sheltered valleys in close proximity to the mining centres which form the sole market for their produce. In the more humid Andes of Ecuador, Colombia and Venezuela mining is of secondary importance, the chief industries are agricultural and the chief exports the products of the tropical levels—cacao in Ecuador; coffee, in Colombia and Venezuela. Here the internal trade is not the supplying of agricultural products to a dominant industry but an exchange of products between zones at different levels and, therefore, of different climates.

Throughout the populated sections of the Andes, transportation between different parts of the plateau, between the plateau and the eastern lowlands, and, to a considerable extent, between the

plateau and the Pacific coast, is still chiefly by pack-trail. The mule has come to be the principal pack-animal, largely supplanting the llama of pre-conquest times, although the latter is still used locally in large numbers. In parts of Colombia the ox is still used for long trips with bulky commodities such as coffee and tobacco, while in the *montañas* of the eastern slopes and in the Choco region of Colombia, transportation is still dependent upon Indian bearers. Everywhere the *arrieros*, or muleteers, are an important element of the population. Often they are grouped in villages or particular districts where their work is the chief source of income. In Colombia it is estimated that they form a third of the population. Whereas the railway has supplanted the pack-train on most of the long routes from the plateau to the Pacific coast, the number of *arrieros* in the Andes as a whole has probably not been decreased, since the penetration of the railways into the plateau has increased the demand for foreign goods and, consequently, for means of distributing them from the railheads.

Except in the broad central plateau of Bolivia, the Andes offer such obstacles to road and railway construction that the west coast republics between Chile and Colombia are effectively divided into two lowland regions separated by the cordilleras. From the point of view of Government administration and national solidarity, railways across the Andes to connect the two lowland regions are of much importance; but so great would be the cost of construction and maintenance that, unless the economic interdependence of the two regions develops to a point where the cost is justified, it is probable that few of the many lines proposed will be constructed. Such rail connections as the mountain zone now has are short lines built to connect important mining or agricultural districts with the nearest seaports. Only two railway routes cross the Andes. The most famous of these is the railway opened in 1911 between Los Andes, Chile and Mendoza, Argentine republic, which crosses the Chile-Argentine boundary by a tunnel 10,000ft. long and 10,500ft. above sea-level, and affords direct rail connection between Buenos Aires and Valparaíso. The recently completed railway from the Bolivia-Argentine boundary to Uyuni connects on the Bolivian *altiplano* with three railways to the Pacific coast, and gives through routes from Buenos Aires to Antofagasta and Arica by rail, and by rail and steamer on Lake Titicaca, to Mollendo. (For railway lines eastward from the *altiplano* of Bolivia see BOLIVIA. For railways which penetrate the Andes in Peru, Ecuador, Colombia and Venezuela, see articles on these countries.) (R. R. P.)

ANDESINE (named by W. H. Abich in allusion to its occurrence in the Andes mountains), a mineral of the plagioclase group of feldspars (*q.v.*) and occupying a position about midway in the isomorphous series, albite-anorthite. In petrology the name is arbitrarily restricted to solid solutions between $\text{Ab}_{70}\text{An}_{30}$ and $\text{Ab}_{60}\text{An}_{40}$. Andesine is an essential constituent of the intermediate igneous rocks, as diorite, porphyrite and andesite.

ANDESITE, a name first applied by C. L. von Buch to a series of lavas, investigated by him, from the Andes, which has passed into general acceptance as the designation of a great family of rocks playing an important part in the geology of most of the volcanic areas of the globe. Not only the Andes but most of the Cordillera of Central and North America consist very largely of andesites; they occur also in great numbers in Hungary, Japan, the Philippines, Java, and New Zealand. They belong to all geological epochs and are frequent among the Ordovician and Devonian rocks of Britain, forming the ranges of the Cheviots, Ochils, Breidden hills, and part of the Lake district. The well-known volcanoes, Montagne Pelée, the Soufrière of St. Vincent, Krakatoa, Tarawera, and Bandaisan have within recent years emitted great quantities of andesitic rocks with disastrous violence.

They are typical intermediate rocks, containing on an average about 60% of silica, but showing a considerable range of composition. Most of them correspond to the plutonic diorites, but others more nearly represent the gabbros. Their essential distinguishing features are mineralogical and consist in the presence of much soda-lime feldspar (ranging from oligoclase to acid labradorite, though phenocrysts may occasionally be still more basic), along with one or more of the ferro-magnesian minerals, biotite, hornblende, augite, and hypersthene. Both olivine and quartz are typically absent, though in some varieties one or other may occur in small quantity. Orthoclase may be present in small amount. In trachyandesites orthoclase and plagioclase are more or less equally developed. These rocks are conspicuously repre-

sented in the igneous fields of the Auvergne, Siebengebirge, Canary islands, etc. The andesites have mostly a porphyritic structure and the larger feldspars and ferro-magnesian minerals are often visible to the naked eye, lying in a finer ground-mass, usually crystalline, but sometimes to a large extent vitreous. When very fresh they are dark-coloured if they contain much glass, but paler in colour, red, grey, or pinkish when more thoroughly crystallized.

The older (pre-Tertiary) andesites are grouped together by many German and, formerly, by British petrologists under the term porphyrites, but are distinguished only by being, as a rule, in a less fresh condition. Apart from this there are three great subdivisions of this family of rocks, the quartz-andesites or dacites, the hornblende- and biotite-andesites, and the augite- and hypersthene-andesites (or pyroxene-andesites). The dacites, a term first applied by Karl Heinrich Hektor Guido Stache (b. 1833) to quartz-bearing andesites of Transylvania or Dacia, contain primary quartz and are the most siliceous members of the family; their quartz may appear in small blebs (or phenocrysts), or may occur only as minute interstitial grains in the ground-mass; other dacites are very vitreous (dacite-pitchstones). In many of their structural peculiarities they closely simulate the rhyolites, from which they differ in containing less potash and more soda, and in consequence less orthoclase feldspar and more plagioclase. The hornblende- and biotite-andesites, like the dacites, have in most cases a pale colour (pink, yellow, or grey), being comparatively rich in feldspar. They resemble the trachytes both in appearance and in structure, but their feldspar is mostly plagioclase, not sanidine. The biotite and hornblende have much the same characters in both of these groups of rocks and are often surrounded by black borders, produced by corrosion and partial resorption by the magma. Augite is common in these andesites, but bronzoite or hypersthene is comparatively rare. The pyroxene-andesites are darker, more basic rocks, with a higher specific gravity, and approach closely to the basalts and dolerites, especially when they contain a small amount of olivine. They are probably the commonest types of andesite, both at the present time and in former geological periods.

In addition to the accessory minerals, zircon, apatite, and iron oxides, which are practically never absent, certain others occur which, on account of their rarity and importance, are of special interest. Sharply-formed little crystals of cordierite are occasionally found in andesites (Japan, Spain, St. Vincent, Cumberland); they seem to depend on more or less complete digestion of fragments of aluminous rocks in the molten lava. Garnet and sapphire have also been found in andesites, and perhaps have the same signification; a rose-red variety of epidote (withamite) is known as a secondary product in certain andesites (Glencoe, Scotland), and the famous red porphyry (*porfido rosso*) of the ancients is a rock of this type. Ore deposits very frequently occur in connection with andesitic rocks (Nevada, California, Hungary, Borneo, etc.), especially those of gold and silver. They have been laid down in fissures as veins of quartz, and the surrounding igneous rocks are frequently altered and decomposed in a peculiar way by the hot ascending metalliferous solutions. Andesites affected in this manner are known as propylites. (J. S. F.)

ANDIJAN. (1) A province in Uzbek S.S.R. Area 7,314 sq.km. Pop. (1926) 792,297 (144,718 urban); (2) a town, the administrative centre of the province. Lat. 40° 55' N. Long. 72° 16' E.; alt. 1,630ft. It is the terminus of the Transcaspian Railway, on the left bank of the upper Syr-Darya. It is in an earthquake area and was destroyed in 1902, but re-built. It is a centre of the cotton trade and has cotton factories (hence the name *Andijani* for merchants in Central Asia). It has gardens and a large park and was formerly the residence of the Khans of Khokand. The province is fertile and is watered by the Syr-Darya. It produces rice, cotton, millet, winter and spring wheat, potatoes, grapes and silk.

AND INTEREST, a term used in the bond market meaning that upon the sale of a bond the quoted price must be supplemented by the payment of an amount equal to the accrued interest to date of sale (*see* ACCRUED INTEREST).

ANDIRON (older form *anderne*), one of a pair of horizontal iron bars upon which logs are laid for burning in an open fireplace.

Andirons stand upon short legs and are usually connected with an upright guard, giving the grotesque appearance of a dog (hence *fire-dogs*, *q.v.*). This guard, being a very conspicuous fixture, is often elaborately designed with figures, grotesque animals, emblems and the like. Andirons with little or no ornament were also used in kitchens, with ratcheted uprights for the spits.

ANDKHUI, northern khanate in Afghan Turkistan, allotted to Afghanistan by the Russo-Afghan boundary commission (1885). Also the chief town of the khanate, 100m. W. of Balkh on the edge of the low Turkoman desert, said to have been founded by Alexander the Great. Having been for a while subject to Bukhara, it was taken and ruined by Mahmud Khan in 1820, and its khan thereupon sought the help of the Afghans. The population has been estimated at 15,000 and includes Turkomans, some Uzbeks and a few Tajiks. The climate is unhealthy, but the soil fertile, the water is brackish, and flies and scorpions abound.

ANDOCIDES, one of the "ten" Attic orators, was born about 440 B.C. Implicated in the mutilation of the Hermæ (415), although he saved his life by turning informer (*see* Thuc. vi. 27, 60) he was condemned to partial loss of civil rights and went into exile. He became a merchant, and after two unsuccessful attempts returned to Athens under the general amnesty that followed the restoration of the democracy (403), and filled some important offices. In 391 he was one of the ambassadors sent to Sparta to discuss peace terms.

Speeches extant:—*De Reditu*, plea for his return and removal of civil disabilities; *De Mysteriis*, defence against the charge of impiety in attending the Eleusinian mysteries; *De Pace*, advocating peace with Sparta; *Contra Alcibiadem*, generally considered spurious. Text:—Blass, 1880, Lipsius, 1888; *De Myst.*, with notes by Hickie, 1885; *De Red.* and *De Myst.*, with notes by Marchant, 1889; *see* Jebb, *Attic Orators*; L. L. Forman, *Index Andocideus*, 1897.

ANDORRA, a small autonomous and semi-independent State on the Franco-Spanish frontier between the central and eastern Pyrenees. Pop. about 5,200. Area, 191sq.m.; with greatest length about 18m., east to west, and greatest breadth 17m. It is a cluster of mountain valleys, uniting to form the Valira, a tributary of the Segre, itself a feeder of the Ebro, surrounded, on all sides save the south-west, by peaks which rise between 5,000 and 10,000ft. No part of the valley is below 3,000ft.; the main Pyrenean crest line, to the north and east is over 8,000 ft. The valleys end in steep *cirques* which give no passage through the mountain wall. The *ports* (passes) of Salud, Fraymiquel and Soldeu are open for a part of the year only; while the defile of the Valira below San-Julia-de-Loria offers little easier, if more permanent, passage for communications with Spain. The climate is severe at all levels, and, above 4,500ft., drought becomes a serious factor, and though most of the valleys are within sub-alpine zones, coniferous forest does not flourish, partly for this reason. Irrigation is thus indispensable to the high meadows, but in the lower valleys large-scale irrigation dates only from 1884. All cultivable areas vary in value according to their exposure to the sun which melts the snows in spring. In the lower valleys torrential activity limits cultivable soil; the widest stretches are about Andorra-la-Vieja. The lateral valleys are in better case, but their alluvial meadows are often too high to be cultivable. The most fertile soil is on artificial terraced slopes. Forests are poor, and have been destroyed by animals and by man for firewood, charcoal, etc. The evergreen oak grows on the sunny slopes around Andorra-la-Vieja, but the olive is nowhere found. At the limits of cultivation bad weather often prevents the ripening of the barley, here sown before or soon after the harvest time. Higher still, in the Alpine zone, are great stretches of summer pasture which provide food for many more sheep than Andorra itself can support through the winter. When the land was first peopled is unknown. At various times the high valleys have doubtless served as refuges for peoples pressed up from the plain, as in the Caucasus, and it is known that French and Spanish deserters have frequently retired there. The Andorran, however, is stubborn and independent, and mistrusts intruders. Pastoral life is naturally well-developed, and the inhabitants of the groups of valleys hold the high pastures in common; a fact which tended towards autonomy in many mountain valleys of the Pyrenees, particularly in

the middle ages. The richest soil is given up to tobacco culture, the crop constituting the main wealth of the country. Exported (mainly contraband) tobacco is found for a great distance around, both in Spain and in the Ariège basin. The need of hay for winter fodder for the sheep further limits cereal culture. Meadowland is highly prized and tends to extend at the expense of the cultivated soil; and even the potato, the introduction of which meant much to most regions of the Pyrenees, forms with barley only a poor supplement to pastoral products. Climate and soil alike are unfavourable to wheat.

Besides the local movement to high pastures in summer there is well developed *transhumance* in the migration of vast flocks of sheep from the distant plains of the lower Segre (Llanos del Urgel) and the Ariège, the total summer flocks of Andorra being estimated at about 30,000 head. In most parts the frontier against France lies in areas which form natural regions, so that treaties, *lies ou paceries*, for peaceful exploitation, regardless of national or political considerations, are of long standing. Against Spain, on the east, the frontier sometimes descends beyond the crests to include the head-waters of opposing streams. Lower down the slopes, herds of horses, mules and cattle find sustenance, while the goat also plays an important part in Andorran life. For all animals, however, the problem is lack of winter food, and the autumnal fairs, visited by Catalan dealers, are very important and are held both in Andorra and over the Spanish border. Industry, apart from the half-dozen tobacco "factories," is merely domestic, and lack of capital and initiative, remoteness and poorness of communications prevent development. Mineral deposits include silver, lead and in particular iron ores, which were formerly worked and reduced with charcoal, as several ruined forges testify. The only roads are bridle-paths, and a municipal road over the Spanish frontier to Seo de Urgel, along which a motor-omnibus service operates. In 1904 France and Spain agreed to build a railway from Ax to Ripoll, which would greatly facilitate traffic, but little progress has been made.

There are two contrasted types of settlement, the permanent and the temporary village, but the houses are grouped together in both cases. The former, extending up to the limit of 6,000ft., are generally on slopes facing south. The largest agglomerations are in the plains about Andorra-la-Vieja and Encamp. The temporary (summer) habitations generally occur between 5,200 and 6,500ft.; but "migration" here is sometimes on a small scale, although in some districts the peasants spend nine months of the year at the high villages (*cortals*). The limited resources of the high valleys necessitate emigration.

The independence of Andorra is traditionally ascribed to Charlemagne, like many other Pyrenean anomalies. Since 1278 the principality has been under the joint suzerainty of the French State (which inherited the rights of the Counts of Foix) and the Spanish bishops of Urgel, and the two powers, who receive annual dues of 960 francs and 460 pesetas respectively, have mutually checked innovations in a land where mediaeval usages naturally persist. Thus Andorra is not a republic; its official title is "les Vallées et Suzerainetés." It is governed by a Council General of 24 members, elected for four years by the heads of families in each of the six parishes of Andorra-la-Vieja, Encamp, La Massana, Ordino, Canillo and San-Julia-de-Loria. A First Syndic, chosen by the Council constitutes the supreme executive; and a Second Syndic serves as deputy. In civil matters the judicial power is exercised in the first instance by two civil judges (*Bayles*) appointed by France and by the bishop respectively. There is a Court of Appeal and also a Supreme Court at Perpignan. The final appeal is either to the supreme court or to the Ecclesiastical Court at Urgel. For criminal suits two magistrates (*Viguers*) preside at Andorra-la-Vieja, the capital, a village of some 600 inhabitants. In the "government house" here the Council General meets. A permanent delegate, the prefect of the department of Pyrénées Orientales, has charge of the interests of France. Spain has shown herself jealous of French encroachments, and some resentment has been shown by the Andorrans themselves, *e.g.*, in 1928. Catalan is the language spoken, and French and Spanish currency are both in use.

ANDOVER, municipal borough, Hampshire, England, situated among low chalk hills on the river Anton, a tributary of the Test. Population (1931) 9,692. The neighbourhood is rich in prehistoric earthworks and *tumuli*. The importance of the Saxon village (Andefeian, Andieura, Andever) is probably related to the proximity of the Roman road from Silchester to Old Sarum. The witenagemot met here, and it is the traditional scene of meeting of Aethelred and Olaf the Dane. Andover existed as a borough before 1176, and Henry II. exempted its inhabitants from toll and passage. The corporation was reconstituted in 1599 and again in 1682. The town possessed an iron market and a prosperous wool trade in the 14th century; it is the centre of a large agricultural district, and also profits from various Army undertakings on the Downs. The November sheep-fair dates from the 13th century. The cattle and corn markets are both ancient institutions. Malting is carried on, and there is a large iron foundry. Extinct industries are the manufactures of silk and parchment. The borough is now in the Basingstoke parliamentary division of Hampshire. The corporation consists of a mayor, four aldermen and 12 councillors. Area 8,663 acres. There is a station on the main S.R. from London to Exeter.

ANDOVER, a town of Essex county, Massachusetts, U.S.A., situated on the south side of the Merrimac Valley. The population was 10,291, 1925 (State census), 9,969 in 1930 (Federal census). The Shawsheen river supplies power for a considerable manufacturing industry. Twine, woollens and rubber goods are produced in Andover, Ballardville, Frye and Shawsheen, a "model" community created by the American Woolen Company. Andover, the principal village, is about 23m. N. of Boston and is served by the Boston and Maine railway and interurban electric lines. The town is noteworthy for its educational institutions. Abbot academy, opened in 1829, was the earliest incorporated school for girls in New England, Phillips academy, opened in 1778 (incorporated in 1780), the first incorporated academy of the State, was founded through the efforts of Samuel Phillips (1752-1802) by his father, Samuel Phillips (1715-90), and his uncle, John Phillips (1719-95), "for the purpose of instructing youth, not only in English and Latin grammar, writing, arithmetic and those sciences wherein they are commonly taught, but more especially to learn them the great end and real business of living." An archaeological department with an important collection in American archaeology, was founded by Robert S. Peabody, and his wife in 1901. The academy grounds include those occupied 1808-1908 by the Andover theological seminary before its removal to Cambridge. Andover was settled about 1643 and incorporated in 1646. It was named after the English town of Andover, Hampshire, the home of some of the chief settlers. North Andover was separated from it in 1855. Elizabeth Stuart Phelps-Ward was born and lived for many years in Andover, and Harriet Beecher Stowe, who resided from 1852 to 1864, is buried there.

ANDRADA E SYLVA, BONIFACIO JOZÉ D' (1765-1838), Brazilian statesman and naturalist, was born at Villa de Santos, near Rio de Janeiro. In 1800 he was appointed professor of geology at Coimbra, and soon after inspector-general of the Portuguese mines; in 1812 he was made perpetual secretary of the Academy of Lisbon. Returning to Brazil in 1819, he urged Dom Pedro to resist the recall of the Lisbon court, and was appointed one of his ministers in 1821. When the independence of Brazil was declared, Andrada was made minister of the interior and of foreign affairs; and when it was established he was again elected by the Constituent Assembly, but his democratic principles resulted in his dismissal from office, July 1823. On the dissolution of the Assembly in November, he was banished to France, where he lived near Bordeaux till, in 1829, he was permitted to return to Brazil. But being again arrested in 1833, and tried for intriguing on behalf of Dom Pedro I., he remained in retirement till he died at Nictheroy in 1838.

ANDRÁSSY, JULIUS, COUNT (1860-1929), Hungarian statesman, was born June 30, 1860, the son of Count Julius Andrassy. He was elected deputy in 1885, and in 1906 became Minister of the Interior, in the so-called Coalition Cabinet. At the collapse of this Ministry in 1910, he refused to join the Khuen-Hédervary Government but declared that he would not actively oppose it, and dissolved the constitutional party, of which he was leader. In 1913 he delivered three speeches in the Hungarian Delegation against the conduct of foreign affairs, advocating a policy of European *détente*, and in parliament he opposed the plan for the centralisation of the internal administration of Hungary. At the outbreak of the World War he supported the Tisza Ministry, but opposed Burian on the Polish and Italian questions. In 1915 he pleaded for peace, and urged a wide extension of the franchise. Upon the resignation of Burian in Oct. 1918, he became foreign minister in Vienna and, in a note to President Wilson, made a last attempt to conclude a separate peace. He then retired from office, but in Jan. 1920 was returned for Miskolcz to the Hungarian National Assembly and later became leader of the Christian National party. In Oct. 1921, at King Charles's second attempt to regain his throne, he was taken prisoner with the king and was imprisoned for several months. In 1922 he was returned to the Nationalist Assembly as a Legitimist deputy. He died June 11, 1929.

His works include—*Ungarns Ausgleich mit Österreich vom Jahre 1867* (1897); *Die Ursachen des Bestandes des Ungarischen Staates und dessen verfassungsmässiger Freiheit* (Budapest, 1901-11); *The Development of Hungarian Constitutional Liberty* (1908); *Wer hat den Krieg verbrochen?* (Leipzig, 1915, Eng. trans. by E. J. Euphrat, New York, 1915); *Interessensolidarität des Deutschtums und Ungar-tums* (Munich, 1916); *Diplomatie und Weltkrieg* (1920, Eng. trans. by J. H. Reece, 1921), and *The Antecedents of the World War*, vol. i., Hungarian (1925).

ANDRÁSSY, JULIUS (GYULA), COUNT (1823-1890), Hungarian statesman, the son of Count Károly Andrassy and Etelka Szapáry, was born at Kočiče, Slovakia (then in north Hungary) on March 3, 1823. In 1846 he attracted attention by his bitter articles against the Government in Kossuth's paper, the *Pesti Hírlap*, and was returned as one of the Radical candidates to the diet of 1847-48. He was one of the leaders in the Constitutional agitation in Hungary, but when Jellačić (*q.v.*) marched into Hungary, Andrassy took command of a Honvéd battalion and served at the battles of Pákozd and Schwechat. In May 1849 Kossuth sent him to Constantinople, in the hope of persuading the Porte to declare war against Austria and Russia. After the catastrophe of Világós he migrated first to London and then to Paris. On Sept. 21, 1851, he was hanged in effigy by the Austrian Government for his share in the Hungarian revolt. In 1856 he married Countess Katinka Kendeffy, and in the following year asked for and obtained an amnesty, without, however, expressing regret for the part he had played in the past. In 1858 he returned to Hungary. Here he supported Deák in his demand for the restitution of the Hungarian Constitution of 1848, and worked strongly for reconciliation, both between the monarch and the Hungarian nation, and the conflicting political parties in Hungary.

On Dec. 21, 1865, he was chosen vice-president of the diet, and in March 1866, president of the sub-committee appointed by the parliamentary commission to draw up the Composition (commonly known as the *Ausgleich*) between Austria and Hungary, of which the central idea, that of the "Delegations," originated with him. After Königgrätz he was formally consulted by the emperor for the first time. He advised the re-establishment of the constitution and the appointment of a responsible ministry.

On Feb. 17, 1867, the king appointed him the first constitutional Hungarian premier, and he took over the departments of war and foreign affairs.

It was he who, in the face of extraordinary opposition, secured for Hungary the recognition of a national militia (Honvéd), organized that force, and arranged for the "provincialization" of the Military Frontier (*q.v.*).

On Nov. 6, 1871, Beust, the Austro-Hungarian foreign minister, who had urged revenge on Prussia for the war of 1866 and a Franco-Austrian alliance, left office, and Andrassy took his place.

He had resolutely opposed the "policy of revenge," notably in his speech of July 28, 1870, and under his guidance Austria-Hungary established that firm friendship with Germany which was the most essential factor in European politics up to 1914. Andrassy was a Magyar, and a man of world-wide outlook; for both reasons he saw in Germany the only trustworthy support of his country and his nation against Russian aggression and the encroachments of the Slavonic nationalities in the dual monarchy and in the Balkans.

Ultimately, Andrassy saw in Russia his most dangerous enemy, but he was able to preserve good relations, and even to secure the signature of an agreement between Franz Joseph and Alexander II. to act together to maintain the peace of Europe (June 6, 1873). Meanwhile his wise and active policy restored Austria-Hungary's fallen international prestige. She was no longer isolated; friendly relations were cultivated with Germany and Russia, and with Great Britain and Italy. The preservation of the Ottoman empire was most desirable for Andrassy's policy; but, should this prove impossible, he did not propose to let Russia's influence eclipse that of Austria-Hungary in the Balkans. At the same time, when court and military circles in Vienna were hoping for an acquisition of territory in the Balkans, Andrassy, fearing the effects on Hungary of an increase of the Slav population in the dual monarchy, resolutely opposed any territorial aggrandisement. Thus, when serious disturbances broke out in Bosnia in 1875, Andrassy, in his famous note of Dec. 30, 1875, urged the introduction of reforms which should leave the authority of the Porte intact, while ameliorating the lot of the Christians. The maintenance of the *status quo* proved impossible; and at the Congress of Berlin, Andrassy, who was present as Austro-Hungarian plenipotentiary, accepted for his country a mandate over Bosnia and Hercegovina far more for defensive, than for offensive, reasons. Nevertheless, the occupation was intensely unpopular in Hungary, as also in German Austria; and on Oct. 8, 1879, Andrassy resigned. The offensive-defensive alliance with Germany, which placed the foreign relations of Austria-Hungary once more on a stable footing, was his work, though it was signed by Haymele.

After his retirement Andrassy continued to take an active part in public affairs both in the Delegations and in the upper house as a moderate Constitutionalist and defender of the *Ausgleich* of 1867. In the last years of his life he regained his popularity, and his death on Feb. 18, 1890, was universally mourned as a national calamity. He was the first Magyar statesman who, for centuries, had occupied a European position. Breadth of view, swift resourcefulness, and an intimate knowledge of men and things were his distinguishing qualities as a statesman. Personally he was the most amiable of men; he united in himself the Magyar magnate and the modern gentleman. If Deák was the architect, Andrassy certainly was the master-builder of the modern Hungarian state.

Count Andrassy left two sons and one daughter, Ilona (b. 1859), who married Count Lajos Batthyány. The elder son, Tivador (Theodore) Andreas (b. July 10, 1857), was elected vice-president of the lower house of the Hungarian parliament in 1890. The younger, Gyula (Julius) is noticed above.

See Andrassy's *Speeches* (Hung.) edited by Béla Lederer (1891); *Memoir* (Hung.) by Benjamin Kállay (1891); *Recollections of Count Andrassy* (Hung.) by Máno Kónyi (1891). *Graf Julius Andrassy: sein Leben und seine Zeit*, by E. von Wertheimer (Stuttgart, 1913).

"ANDRÁSSY NOTE, THE," a declaration drawn up by Count Andrassy on behalf of Russia, Austria and Germany, and presented to the Porte, after the adherence of France and Great Britain, on Jan. 31, 1876. Serious insurrections had broken out in Bosnia and Hercegovina. The Andrassy note was an attempt at conciliation: it urged the equality before the law of Christian and Muslim subjects, the abolition of the system of farming taxes, and the erection of an administrative local assembly representing both religions. Neither the Andrassy note nor the subsequent Berlin memorandum (to which Great Britain refused any support) was successful. Serbia and Montenegro declared war. The "Bulgarian atrocities" followed, precipitating the Russo-Turkish War, which was closed by the treaties of San Stefano and Berlin, 1878 (*qq.v.*). (See also **EASTERN QUESTION.**)

ANDRÉ, JOHN (1751-1780), British soldier, was born in London in 1751 of Genevese parents. Accident brought him in 1769 to Lichfield, where, in the house of the Rev. Thomas Seward, he met the beautiful Miss Honora Sneyd. A strong attachment sprang up between the two, but Miss Sneyd's family refused their consent to marriage. André travelled for some time in Germany, and eventually joined the 7th Royal Fusiliers in

BY COURTESY OF YALE UNIVERSITY LIBRARY

MAJOR JOHN ANDRÉ, BRITISH SOLDIER AND PATRIOT, WHO WAS HANGED AS A SPY, DURING THE AMERICAN REVOLUTION. FROM A SKETCH MADE BY ANDRÉ ON THE MORNING OF THE DAY FIXED FOR HIS EXECUTION

Canada. Honora married in 1773 R. L. Edgeworth, the father of Maria Edgeworth, but André remained faithful. In a letter to Anna Seward, written shortly after being taken prisoner by the Americans at the capitulation of St. John's on Nov. 3 1775, he states that he has been "stripped of everything except the picture of Honora, which I concealed in my mouth. Preserving this I yet think myself fortunate." Exchanged towards the close of 1776, André received rapid promotion, and Sir Henry Clinton appointed him adjutant-general of the forces in 1778.

Early in 1780 the American general, Benedict Arnold (q.v.), made overtures to the British to betray to them the fortress of West Point on the Hudson river. Major André was appointed to negotiate with Arnold. For this purpose he landed from a vessel bearing a flag of truce and saw Arnold, who gave him full particulars and plans of the fortress of West Point, and arranged to co-operate with the British during an attack which was to be made in a few days. Unfortunately for André, the British vessel was fired on before the negotiations were finished and obliged to drop down the river. André was compelled to pass the night within the American lines. Exchanging his uniform for a civilian disguise, he set out next day by land for New York, provided by Arnold with a passport. When all danger of being recognized seemed past, André was stopped by three American militiamen who searched him and discovered in his boots the proofs of his negotiations for the betrayal of West Point. Washington, although admitting that André was "more unfortunate than criminal," sent him before a court-martial, by which, he was, in consequence of his own admissions, condemned to death as a spy. He was hanged at Tappan on Oct. 2 1780. Arnold escaped by flight. The justice of André's execution has been much discussed, but he undoubtedly acted as a spy, although under orders and entirely contrary to his own feelings. Washington's apparent harshness in refusing the condemned man a soldier's death by shooting has also been censured.

Major André showed considerable poetic talent in his humorous *Cow-chase*, a parody on *Chevy-chase*, which appeared in three successive parts in New York, the last on the very day of his capture. His fate excited universal sympathy, and the whole British army went into mourning for him. A mural tablet to his memory was placed in Westminster Abbey by the British Government; a monument to his captors has been erected by Americans on the spot where he was taken. André's military journal of the

British movements in America from June 1777 to the close of 1778, was taken to England in 1782 by General Grey, whose descendant, Earl Grey, discovered it in 1902.

BIBLIOGRAPHY.—See Sargent-Winthrop, *The Life and Career of Major John André, etc.*, (new ed., New York, 1902); *André's Journal* (Boston, Mass., The Bibliophile Society, 1904).

ANDRÉ LE CHAPELAIN (ANDREAS CAPELLANUS), mediaeval French writer and chaplain at the French court (whence his surname), was born in the second half of the 12th century, and probably held his office under Philip Augustus (1180–1223). His famous treatise, *Liber de Arte honeste amandi et de Reprobatione inhonesti Amoris*, written in Latin at the beginning of the 13th century and translated twice into French during the century, is an interesting source of information concerning mediaeval manners and morals, and the "court of love" in particular. There are 12 mss. extant, of which the most important are: the 13th century ms. in the Vatican, coll. Ottobonianæ, no. 1463; the 14th century ms. in the Bibliothèque Nationale, no. 8758; and the 15th century ms. in the Ambrosian Library, A. no. 136. The work has also been translated into German and Italian. The most widespread edition is that of D. Mühler, *Erotica seu Amatoria Andrei Capellani regii* (Dortmund, 1610); other editions are by E. Trojel, *Andreas Capellani regii Francorum De Amore libri tres* (Copenhagen, 1892); and by H. M. Elster, a German translation, *3 Bücher über die Liebe . . .* (1924).

ANDREA, GIOVANNI (1275–1348), professor of canon law at Bologna, where he is said to have died of plague. Curious stories are told of him, e.g., that by way of self-mortification he lay every night for 20 years on the bare ground with only a bear's skin for a covering; that in an audience he had with Pope Boniface VIII. his extraordinary shortness of stature led the pope to believe he was kneeling, and to ask him three times to rise, to the immense merriment of the cardinals; and that he had a daughter, Novella, so accomplished in law as to be able to read her father's lectures in his absence, and so beautiful that she had to read behind a curtain lest her face should distract the attention of the students.

ANDREA DEL SARTO (1486–1531), Italian painter, was born in Florence on July 16, 1486. There were four other children. His surname has been given as Vanucchi; his name "del Sarto" was given him because his father, Agnolo, was a tailor. In 1494 Andrea was put to work under a goldsmith. He took to drawing from his master's models and was soon transferred to a skilful woodcarver and inferior painter named Gian Barile, with whom he remained until 1498. Barile recommended him to Piero di Cosimo as draughtsman and colourist. Piero retained Andrea for some years, allowing him to study from the famous cartoons of Leonardo da Vinci and Michelangelo. Finally Andrea agreed with his friend Franciabigio, who was somewhat his senior, that they would open a shop conjointly; at a date not defined they took a lodging together in the Piazza del Grano. Their first work in partnership may probably have been the "Baptism of Christ," for the Florentine Compagnia dello Scalzo. Soon afterwards the partnership was dissolved. From 1509 to 1514 the brotherhood of the Servites employed Andrea, as well as Franciabigio and Andrea Feltrini, the first-named undertaking in the portico of the Annunziata three frescoes illustrating the life of the Servite saint Filippo Benizzi (d. 1285). The subjects are the saint sharing his cloak with a leper, cursing some gamblers, and restoring a girl possessed with a devil. The second and third works excel the first, and are impulsive and able performances. These paintings gained for their author the pre-eminent title "Andrea senza errori" (Andrew the unerring). Andrea went on to the Death of S. Filippo and the Children cured by touching his Garment—all the five works being completed before the close of 1510. The youth of 23 was already, in technique, about the best fresco-painter of central Italy, barely rivalled by Raphael, who was the elder by four years. Michelangelo's Sistine frescoes were then only in a preliminary stage. Andrea always worked in the simplest, most typical, and most trying method of fresco—that of painting the thing once and for all, without any subsequent dry-touching. He now received many commissions. The brotherhood of the Servites engaged him to do two more frescoes in the Annunziata

at a higher price; he also painted, towards 1512, an Annunciation in the monastery of S. Gallo.

The "Tailor's Andrew" appears to have been an easy-going plebeian, to whom a modest position in life and scanty gains were no grievances. As an artist he must have known his own value; but he probably rested content in the sense of his superlative powers as an executant, and did not aspire to the rank of a great inventor or leader, for which, indeed, he had no vocation. He led a social sort of life among his compeers of the art, was intimate with the sculptor Rustici, and joined a jolly dining-club at his house named the Company of the Kettle, also a second club named the Trowel. At one time, Franciabigio being then the chairman of the Kettle-men, Andrea recited, and is by some regarded as having composed, a comic epic, "The Battle of the Frogs and Mice"—a rechauffé, as one may surmise, of the Greek *Batrachomyomachia*. He fell in love with Lucrezia (del Fede), wife of a hatter named Carlo Recanati; the hatter dying opportunely, on Sept. 1, 1516, Andrea married her. She was a very handsome woman and has come down to us treated with great suavity in many a picture of her lover-husband, who constantly painted her as a Madonna and otherwise; and even in painting other women he made them resemble Lucrezia in general type. Vasari, who was at one time a pupil of Andrea, describes her as faithless, jealous, overbearing, and vixenish with the apprentices. She lived to a great age, surviving her husband 40 years.

By 1514 Andrea had finished his last two frescoes in the court of the Servites, the "Nativity of the Virgin," which shows the influence of Leonardo, Domenico Ghirlandajo, and Fra Bartolommeo in effective fusion, and the "Procession of the Magi," intended as an amplification of a work by Baldovinetti; in this fresco is a portrait of Andrea himself. He also executed at some date a much-praised head of Christ over the high altar. By Nov. 1515 he had finished at the Scalzo the allegory of Justice, and the "Baptist preaching in the desert"—followed in 1517 by "John baptizing" and other subjects. Before the end of 1516 a "Pieta" of his composition and afterwards a Madonna were sent to the French court. At the invitation of Francis I. Andrea went in June 1518 to Paris, where, for the first and only time in his life he was handsomely remunerated. Lucrezia, however, wrote urging his return to Italy. The king assented on the understanding that his absence from France was to be short; and he gave Andrea a sum of money to be expended in purchasing works of art for his royal patron. Andrea spent the king's money and some of his own in building a house for himself in Florence.

In 1520 he resumed work in Florence, and executed the "Faith" and "Charity" in the cloister of the Scalzo. These were succeeded by the "Dance of the Daughter of Herodias," the "Beheading of the Baptist," the "Presentation of his head to Herod," an allegory of Hope, the "Apparition of the Angel to Zacharias" (1523), and the monochrome of the Visitation (1524). In 1525 he painted the very famous fresco named the "Madonna del Sacco," a lunette in the cloisters of the Servites, generally accounted his masterpiece. His final work at the Scalzo was the "Birth of the Baptist" (1526), executed with some enhanced elevation of style after Andrea had studied Michelangelo's figures in the sacristy of S. Lorenzo. In the following year he completed at S. Salvi, near Florence, a celebrated "Last Supper," in which all the personages seem to be portraits. This also is a very fine example of his style, though the conception of the subject is not exalted. It is the last monumental work of importance which Andrea del Sarto lived to execute. He caught the plague at Florence, and died on Jan. 22, 1531, at the comparatively early age of 43. He was buried in the church of the Servites.

Of the various portraits by Andrea said, though with doubtful reason, to represent himself, one, an admirable half-figure is in the National Gallery, London; others are in the gallery at Panshanger, in the Uffizi Gallery and the Pitti Palace. Other of his works are: in the Uffizi, the "Madonna di S. Francesco," or "Madonna delle Arpie," from certain figures of harpies which are decoratively introduced, c. 1517, and the altar-piece painted for the monastery of S. Gallo, the "Fathers disputing on the doctrine of the Trinity," c. 1517; in the Louvre, "Charity," perhaps the

only painting which Andrea executed while in France; in the Belvedere of Vienna, "The Pietà"; at Poggio a Caiano—a celebrated fresco (1521), completed by Alessandro Allori, representing Julius Caesar receiving tribute—various figures bringing animals from foreign lands; in the Pitti Gallery two separate compositions of the "Assumption of the Virgin," also a fine "Pietà"; in the Madrid museum the "Virgin and Child"; in the Louvre the "Holy Family," the Baptist pointing upwards; in Berlin a portrait of his wife; and in Panshanger a fine portrait named "Laura." The Uffizi and the Louvre possess many fine drawings from nature by his hand.

In 1523 Andrea del Sarto produced at the request of Ottaviano de' Medici a copy of the portrait group of Leo X. by Raphael; it is now in the Naples museum, the original being in the Pitti Gallery. Even Giulio Romano, who had himself manipulated the original to some extent, was misled.

Andrea had true pictorial style, a very high standard of correctness and an enviable balance of executive endowments. The point of technique in which he excelled least was perhaps that of discriminating the varying textures of different objects and surfaces. There is not much elevation or ideality in his works—much more of reality. His chiaroscuro is not carried out according to strict rule, but is adjusted to his liking for harmony of colour and fused tone and transparency; in fresco more especially his predilection for varied tints appears excessive. It may be broadly said that his taste in colouring was derived mainly from Fra Bartolommeo, and in form from Michelangelo; and his style partakes of the Venetian and Lombard, as well as the Florentine and Roman—some of his figures are even adapted from Albert Dürer. In one way or other he continued improving to the last. It is in his portraits that Andrea ranks among the greatest.

In this account of Andrea del Sarto the main lines of the narrative of Crowe and Cavalcaselle, supplemented by Vasari, Lanzi, and others, have been followed.

See H. Guinness, *Andrea del Sarto* (1899); F. Knapp, *Andrea del Sarto* (Beilefeld and Leipzig, 1907); C. Pfeiffer, *Les Madones d'Andrea del Sarto Étude Critique* (1913).

ANDREANI, ANDREA, Italian engraver on wood, in chiaroscuro, was born at Mantua about 1540 (Brulliot says 1560) and died at Rome in 1623. His engravings are scarce and valuable, and are chiefly copies of Mantegna, Dürer, and Titian.

ANDREE, KARL (1808–1875), German geographer, was born at Brunswick on Oct. 20, 1808, and died at Wildungen on Aug. 10, 1875. He was educated at Jena, Göttingen, and Berlin. From 1855 he devoted himself entirely to geography and ethnography, working successively at Leipzig and at Dresden. In 1862 he founded the important geographical periodical *Globus*. His works include *Nordamerika in geographischen und geschichtlichen Umrissen* (Brunswick, 1854), *Geographische Wanderungen* (Dresden, 1859), and an important *Geographie des Welthandels* (Stuttgart, 1867–72).

His son **RICHARD** (1835–1912) devoted himself especially to ethnography, but he also had a chief share in the production of the *Physikalisch-statistische Atlas des deutschen Reiches* (Leipzig, 1877), *Allgemeine Handatlas* (1st ed. 1881), and other atlases; and he continued the editorship of the *Globus*.

ANDRÉE, SALOMON AUGUST (1854–1897), Swedish engineer, was born at Grenna, on Lake Vetter, Oct. 18 1854. After education at the Stockholm technical college, he studied aeronautics, and in 1895 elaborated a plan for crossing the north polar region by a balloon which should be in some degree dirigible by sails and trailing ropes. After an abortive effort in 1896, the winds being contrary, Andrée started with two companions from Danes Island, Spitsbergen, on July 11 1897. They were never seen again. Of several expeditions sent in search of them, the first started in Nov. 1897, on the strength of a report of cries of distress heard by shipwrecked sailors at Spitzbergen; in 1898 and 1899 parties searched the north Asiatic coast and the New Siberia Islands; and in May 1899 Dr. Nathorst headed an expedition to eastern Greenland. None was successful, but on August 6, 1930, thirty-three years later, men from a sealer landed on White Island, and accidentally discovered the remains of the

Andrée expedition, including two bodies; the third was found later. It appeared from Andrée's diary that the balloon drifted to 83° 4' N., but soon was forced down. Andrée and his companions succeeded in reaching White Island but perished there.

ANDREINI (ahn'dra-ē'nē), **FRANCESCO**, Italian actor, was born at Pistoia in the latter half of the 16th century. He was a member of the company of the *Gelosì* which Henry IV. summoned to Paris to please his bride, Marie de' Medici. His wife **ISABELLA ANDREINI** (1562–1604) was a distinguished actress, and also a minor poet. Her books included a pastoral, *Mirtilla* (Verona, 1588), a volume of songs, sonnets and other poems (Milan, 1601), and a collection of letters, published after her death. Her distinguished son **GIAMBATTISTA ANDREINI** (1578–1650), actor and playwright, was born in Florence, and acted in Paris under the name of Leylio. Italian writers have surmised that one of his plays, *L'Adamo* (Milan, 1613), suggested to Milton the idea of *Paradise Lost*.

ANDRÉOSSY, ANTOINE-FRANÇOIS, COUNT (1761–1828), French artillery officer and diplomatist, was born March 6 1761. He served in the French Revolutionary wars on the Rhine, in Italy and in Egypt, and took part in the *coup d'état* of the 18th Brumaire. During the short peace which followed the treaties of Amiens and Lunéville he was ambassador to England, but his repeated warnings to Napoleon that the British Government desired to maintain peace, but must be treated with consideration, were disregarded. Later Napoleon sent Andréossy as ambassador in 1808 to Vienna and in 1812 to Constantinople. After his recall by Louis XVIII. in 1814 he retired into private life, and wrote works on military history and scientific memoirs. He died at Montauban in 1828.

See Marion, *Notice nécrologique sur le Lt.-Général Comte Andréossy*.

ANDRES, JUAN (1740–1817), Spanish Jesuit, wrote on science, music, etc., but his chief work was *Dell'origine, progressi, e stato attuale d'ogni Letteratura* (Parma, 1782–99). A Spanish translation was made by his brother Carlos (Madrid, 1784–1806), and an abridgment in French (1838–46) was compiled by Alexis Nerbonne.

See C. Sommervogel, *Bibliothèque de la compagnie de Jésus, première partie* (Brussels and Paris), vol. i. col. 342–350.

ANDREW, ST., the Apostle (see **APOSTLE**).

ANDREW II. (1175–1235), king of Hungary, son of Bela III., succeeded his nephew, the infant Ladislas III., in 1205. By his reckless generosity Andrew impoverished the crown, and made the monarchy dependent on the great feudatories, who reduced Hungary to a state bordering on anarchy. His first wife, Gertrude of Meran, was murdered (Sept. 24 1213) by rebellious nobles. In 1217 Andrew set out for the Holy Land with an army of 15,000 men, about 10,000 of whom sailed from Venice to Acre. The expedition failed, and on Andrew's return the barons extorted from him the Golden Bull which has been called the Hungarian *Magna Carta*. Andrew was thrice married. St. Elizabeth of Hungary was his daughter by his first wife, Gertrude.

BIBLIOGRAPHY.—No special monograph for the whole reign exists, but there is a good description of Andrew's crusade in Reinhold Roehricht, *Geschichte des Königreiches Jerusalem* (Innsbruck, 1898). The best account of Andrew's government is in László Szalay's *History of Hungary* (Hung.), vol. i. (Leipzig and Budapest, 1851–62).

ANDREW, JOHN ALBION (1818–1867), American political leader, "war governor" of Massachusetts, was born at Windham, Me., on May 31, 1818. He graduated at Bowdoin college in 1837, studied law in Boston, was admitted to the Suffolk bar in 1840, and practised his profession in Boston. He also took a deep interest in religious matters, was a prominent Unitarian and was assistant editor for some time of *The Christian World*. With ardent anti-slavery principles, he entered political life as a "Young Whig" opposed to the Mexican War; he became an active Free-Soiler in 1848, and in 1854 took part in the organization in Massachusetts of the new Republican party. He served one term, in 1858, in the State house of representatives. In 1859 he took such an active part in raising funds to defend John Brown, then on trial in Virginia, that he aroused the suspicions of a senatorial committee investigating Brown's raid, and was sum-

moned to Washington to tell what he knew of the affair. In 1860 he was chairman of the Massachusetts delegation to the Republican national convention at Chicago, which nominated Lincoln for the presidency; and from 1861 to January 1866, throughout the trying period of the Civil War, he was governor of Massachusetts, becoming known as one of the ablest, most patriotic and most energetic of the remarkable group of "war governors" in the North.

Immediately after his inauguration he began filling the militia regiments with young men ready for active service, saw that they were well drilled and supplied them with good modern rifles. As a result, Massachusetts was the only northern State in any way prepared for war when the Confederates fired on Fort Sumter; and her troops began to muster in Boston on April 16, the very day after President Lincoln's call for volunteers. On the next day the 6th Massachusetts Volunteer Infantry started south for the defence of Washington, and was the first fully armed and equipped volunteer regiment to reach the capital. Within six days after the call, nearly 4,000 Massachusetts volunteers had departed for Washington. In 1863, at Governor Andrew's own request, the secretary of war authorized him to raise several regiments of negro troops, with white commissioned officers, and the 54th Massachusetts Infantry was the first regiment of free negroes raised in the North. Governor Andrew's example was quickly followed in other States, and before the end of the year 36,000 negroes had been enrolled in the Union armies. When the War Department ruled that the negro troops were entitled to pay only as "labourers" and not as soldiers, Governor Andrew used all his influence with the president and the secretary of war to secure for them the same pay as white troops, and was finally successful. Notwithstanding his loyal support of the administration during the struggle, he did not fully approve of its conduct of the war, which he deemed shifting and timid; and it was with great reluctance that he supported Lincoln in 1864 for a second term.

In 1865 Andrew rejected the more radical views of his party as to the treatment to be accorded to the late Confederate States, opposed the immediate and unconditional enfranchisement of freedmen, and, though not accepting President Johnson's views in their entirety, he urged the people of Massachusetts to give the new president their support. On retiring from the governor's office he resumed the practice of law, at once achieving great success. In 1865 he presided at the first national convention of the Unitarian Church. He died suddenly of apoplexy, at Boston, on Oct. 30, 1867.

See Henry G. Pearson, *Life of John A. Andrew* (Boston and New York, 1904).

ANDREWES, LANCELOT (1555-1626), bishop of Winchester, was born in London. His family was an ancient Suffolk one; his father, Thomas, became master of Trinity House. Lancelot was educated at Merchant Taylors' school and at Pembroke Hall, Cambridge, and became a fellow of his college in 1576. He took orders in 1580, and his preferment was rapid. He was vicar of St. Giles's, Cripplegate (1588), prebendary of St. Paul's (1589), of Southwell (1589-1609), dean of Westminster (1601), bishop of Chichester (1605), of Ely (1609), and of Winchester from 1618 until his death, Sept. 26 1626. He was one of those who prepared the authorized version of the Bible (1611).

Two generations later, Richard Crashaw caught up the universal sentiment, when, in his lines "Upon Bishop Andrewes' Picture before his Sermons," he exclaims:—

"This reverend shadow cast that setting sun,
Whose glorious course through our horizon run,
Left the dim face of this dull hemisphere,
All one great eye, all drown'd in one great teare."

Andrewes was distinguished in many fields. At court, though no trifier or flatterer, he was a favourite counsellor in three successive reigns, but he never meddled much in civil or temporal affairs. His learning made him the equal and the friend of Grotius, and of the foremost contemporary scholars. His preaching was a unique combination of rhetorical splendour and scholarly richness; his

piety that of an ancient saint, semi-ascetic and unearthly in its self-denial. As a churchman he is typically Anglican, equally removed from the Puritan and the Roman positions. He stands in true succession to Richard Hooker in working out the principles of the English Reformation, though while Hooker argued mainly against Puritanism, Andrewes chiefly combated Romanism. A good summary of his position is found in his *First Answer to Cardinal Perron*, who had challenged James I.'s use of the title "Catholic." His position in regard to the Eucharist is naturally more mature than that of the first reformers. "As to the Real Presence we are agreed; our controversy is as to the *mode* of it. As to the mode we define nothing rashly, nor anxiously investigate, any more than in the Incarnation of Christ we ask how the human is united to the divine nature in One Person. There is a real change in the elements—we allow *ut panis iam consecratus non sit panis quem natura formavit; sed, quem benedictio consecravit, et consecrando etiam immutavit*" (*Responsio*, p. 263). Adoration is permitted, and the use of the terms "sacrifice" and "altar" maintained as being consonant with scripture and antiquity. Christ is "a sacrifice—so, to be slain; a propitiatory sacrifice—so, to be eaten" (*Sermons*, vol. ii. p. 296). "By the same rules that the Passover was, by the same may ours be termed a sacrifice. In rigour of speech, neither of them; for to speak after the exact manner of divinity, there is but one only sacrifice, *veri nominis*, that is Christ's death. And that sacrifice but once actually performed at His death, but ever before represented in figure, from the beginning; and ever since repeated in memory to the world's end. That only absolute, all else relative to it, representative of it, operative by it. . . . Hence it is that what names theirs carried, ours do the like, and the Fathers make no scruple at it—no more need we" (*Sermons*, vol. ii. p. 300). As to reservation, "it needeth not: the intent is had without it," since an invalid may always have his private communion. Andrewes declares against the invocation of saints, the apparent examples in patristic literature are "rhetorical outbursts, not theological definitions." His services to his church have been summed up thus: (1) he has a keen sense of the proportion of the faith and maintains a clear distinction between what is fundamental, needing ecclesiastical commands, and subsidiary, needing only ecclesiastical guidance and suggestion; (2) as distinguished from the earlier protesting standpoint, e.g. of the 39 Articles, he emphasized a positive and constructive statement of the Anglican position.

LITERATURE.—Of his works the *Manual of Private Devotions* is the best known, for it appeals to Christians of every church. One of the many good modern editions is that by Alex. Whyte (1900). Andrewes's other works occupy eight volumes in the Library of Anglo-Catholic Theology (1841-54). Of biographies we have those by H. Isaacson (1650), A. T. Russell (1863), R. L. Ottley (1891), and Dean Church's essay in *Masters in English Theology*. See also W. H. Frere, *Lancelot Andrewes as a Representative of Anglican Principles* (1898; Church Hist. Soc. Publications, No. 44).

ANDREW OF LONGJUMEAU (Longumeau, Lonjumel, etc.), a French Dominican, explorer and diplomatist. He accompanied the mission under Friar Ascelin, sent by Pope Innocent IV. to the Mongols in 1247; at the Tartar camp near Kars he met a certain David, who next year (1248) appeared at the court of King Louis IX. of France in Cyprus. Andrew, who was now with St. Louis, interpreted to the king David's message, a real or pretended offer of alliance from the Mongol general, Ilchikdai (Ilchikadai), and a proposal of a joint attack upon the Islamic powers for the conquest of Syria. In reply the French sovereign despatched Andrew as his ambassador to the great Khan Kuyuk; with Longjumeau went his brother, a monk, and several others—John Goderiche, John of Carcassonne, Herbert "le sommelier," Gerbert of Sens, Robert a clerk, a certain William, and an unnamed clerk of Poissy.

The party set out about Feb. 16 1249, with letters from King Louis and the papal legate, and rich presents, including a chapel-tent, lined with scarlet cloth and embroidered with sacred pictures. From Cyprus they went to the port of Antioch in Syria, and thence travelled for a year to the khan's court, going ten leagues a day. Their route led them through Persia, along the

southern and eastern shores of the Caspian (whose inland character, unconnected with the outer ocean, their journey helped to demonstrate), and probably through Talas, N.E. of Tashkent. On arrival at the supreme Mongol court—either that on the Imyl river (near Lake Ala-kul and the present Russo-Chinese frontier in the Altai), or more probably at or near Karakorum itself, S.W. of Lake Baikal—Andrew found Kuyuk Khan dead, poisoned, as the envoy supposed, by Batu's agents. The regent-mother, Ogul Gaimish (the "Camus" of Rubruquis), seems to have received and dismissed him with presents and a letter for Louis IX., the latter a fine specimen of Mongol insolence. But it is certain that before the friar had quitted "Tartary," Mangu Khan, Kuyuk's successor, had been elected.

Andrew's report to his sovereign, whom he rejoined in 1251 at Caesarea in Palestine, appears to have been a mixture of history and fable; the latter affects his narrative of the Mongols' rise to greatness, and the struggles of their leader, evidently Jenghiz Khan, with Prester John; it is still more evident in the position assigned to the Tartar homeland, close to the prison of Gog and Magog. On the other hand, the envoy's account of Tartar manners is fairly accurate, and his statements about Mongol Christianity and its prosperity, though perhaps exaggerated (e.g., as to the 800 chapels on wheels in the nomadic host), are based on fact. Mounds of bones marked his road, witnesses of devastations which other historians record in detail; he found Christian prisoners from Germany in the heart of "Tartary" (at Talas); the ceremony of passing between two fires he was compelled to observe, as a bringer of gifts to a dead khan, gifts which were of course treated by the Mongols as evidence of submission.

We only know of Andrew through references in other writers; see especially William of Rubruquis in *Recueil de voyages*, iv. (Paris, 1839), pp. 261, 265, 279, 296, 310, 353, 363, 370; Joinville, ed. Francisque Michel (1858, etc.), pp. 142, etc.; Jean Pierre Sarrasin, in same vol., pp. 254-5; William of Nangis in *Recueil des historiens des Gaules*, xx. 359-67; Rémusat, *Mémoires sur les relations politiques des princes chrétiens . . . avec les . . . Mongols* (1822, etc.), p. 52. (C. R. B.)

ANDREWS, CHARLES MC LEAN (1863-), American educator and historian, was born in Weathersfield, Conn., on Feb. 22, 1863. He was educated at Trinity college, Hartford, Conn., graduating in 1884, and at Johns Hopkins university he received the degree of doctor of philosophy in 1889. He was associate professor and professor of history in Bryn Mawr college from 1889 to 1907 and professor of history in Johns Hopkins university from 1907 to 1910 when he became professor of American history in Yale university. He has been actively associated with many historical societies and has contributed numerous articles to reviews and historical journals.

Among his extensive historical writings are: *The River Towns of Connecticut* (1889); *The Old English Manor* (1892); *The Historical Development of Modern Europe* (1896-98); *Contemporary Europe, Asia and Africa, 1871-1901* (1902); *A History of England*, a text-book (1903); "Colonial Self-Government, 1652-1689," vol. v. of *The American Nation, a History* (1904); *British Commissions, Councils and Committees, 1622-1675* (1908); *A Short History of England* (1912); *The Colonial Period of American History* (1912); *The British Merchants and the Non-Importation Movement* (1917); *Fathers of New England and Colonial Folkways* (in "Chronicles of America" Series, 1919); *The Colonial Background of the American Revolution* (1924).

ANDREWS, ELISHA BENJAMIN (1844-1917), American educator, was born in Hinsdale, N.H., on Jan. 10, 1844. At the outbreak of the Civil War he entered the Union army and was wounded, losing an eye, at Petersburg, in 1864. He graduated from Brown university in 1870 and from Newton theological institution, Newton Centre, Mass., in 1874. From 1875 to 1879 he was president of Denison university, Granville, Ohio. In 1879-82 he was professor of homiletics in Newton theological institution and from 1882 to 1888 he was professor of history and political economy in Brown university. He became professor of political economy at Cornell university in 1888, and in 1889 was made president of Brown university. In 1897, because of criticism by the trustees of his advocacy of free silver, he resigned, but soon withdrew his resignation. He served as superintendent of the public schools of Chicago from 1898 to 1900, when he was

chosen chancellor of the University of Nebraska, from which he retired as chancellor emeritus in 1909. He died at Interlaken, Fla., on Oct. 30, 1917.

In addition to text-books on history and economics, his published works include *An Honest Dollar* (1889); *Wealth and Moral Law* (1894); *History of the United States* (1894); and *The History of the Last Quarter Century in the United States, 1870-95* (1896), revised as *The United States in Our Own Time* (1903).

ANDREWS, JAMES PETTIT (c. 1737-1797), English historian and antiquary, was born at Shaw House, Newbury, Berkshire, and died in London on Aug. 6, 1797. He was one of the magistrates at the police court in Queen Square, Westminster, from 1792 to his death. His chief work was a *History of Great Britain connected with the Chronology of Europe from Caesar's Invasion to Accession of Edward VI.* (1794-95).

ANDREWS, ROY CHAPMAN (1884-), American naturalist and explorer, was born at Beloit, Wis., on Jan. 26, 1884. Immediately after his graduation from Beloit college in 1906 he entered the American Museum of Natural History, New York, and went to Alaska on his first exploring trip in 1908. In 1909-10 he accompanied, as a naturalist, the "U.S.S. Albatross" on its voyage to the Dutch East Indies, Borneo and Celebes; in 1911-12 he explored northern Korea; and in 1913 was with the Borden Alaska expedition. The same year he received the degree of M.A. from Columbia university.

Until 1914 he specialized in the study of whales and other water mammals. From that date he devoted himself, as chief of the division of Asiatic exploration of the American Museum of Natural History, to the exploration of the lesser known portions of Central Asia, China and Borneo, also serving in the U.S. Intelligence service in China, in 1918. The expeditions under his leadership explored successively, Tibet, southwest China, Burma, North China, Mongolia and Central Asia. In Mongolia they found some of the richest fossil fields known to the world. The fruits of the expeditions which he led in 1921-22 and 1925 into Central Asia included the discovery of new geological formations, large fossil fields, dinosaur eggs, and the skull and other parts of the *Baluchitherium*—the largest known land mammal.

The expeditions discovered the oldest known mammals and extensive evidence of primitive human life on the Central Asian plateau. Evidence was discovered also pointing to Central Asia as a place of origin and centre of distribution for much of the reptilian and mammalian life of the world. The expeditions continued work in Central Asia until 1929.

He has written *Whale Hunting with Gun and Camera* (1916), *Camps and Trails in China*, with Yvette Borup Andrews (1918), *Across Mongolian Plains* (1921), *On the Trail of Ancient Man* (1926-27), *Ends of the Earth* (1929) and numerous monographs and scientific bulletins of the American Museum of Natural History and other scientific institutions.

ANDREWS, THOMAS (1813-1885), Irish chemist and physicist, was born on Dec. 19, 1813, at Belfast, where his father was a linen merchant. In 1845 he was appointed vice-president of the newly established Queen's college, Belfast, and professor of chemistry, offices which he held till 1879, when failing health compelled his retirement. He died on Nov. 26, 1885. The work on which his reputation mainly rests, and which best displayed his skill and resourcefulness in experiment, was concerned with the liquefaction of gases. He carried out a very complete enquiry into the laws expressing the relations of pressure, temperature and volume in carbonic dioxide, in particular establishing the conceptions of critical temperature and critical pressure, and showing that the gas passes from the gaseous to the liquid state without any breach of continuity.

His scientific papers were published in a collected form in 1889 with a memoir by Profs. Tait and Crum Brown.

ANDREYEV, LEONID NICOLAIEVICH (1871-1919), Russian novelist, was born in Orel on June 18, 1871. He was educated at the government school. Poverty and an unhappy heredity drove him, in 1894, to an attempt on his own life, as a result of which he suffered from a weak heart, which ultimately caused his death. He became a reporter on *The Courier*. Then, in 1899, his story *They Lived* appeared in the monthly *Zhizn*

("Life") and attracted universal attention. It is the only work of Andreyev which contains a happy love-story.

In 1901, when the first series of his stories appeared in a separate edition, N. K. Michailovsky, the most influential critic of the time, paid a high tribute to the genius of the young author. This series included the stories *The Grand Slam*, *The Tocsin*, *The Wall*, in which Andreyev's creative genius and its characteristics were clearly visible. His subsequent works, *The Story of Serguey Petrovitch*, *Thought*, *In the Mist*, *The Life of Father Vassili Fiveisky*, *Ghosts*, etc., are similar to his first work in spirit and philosophical outlook.

His works are permeated by horror of life, which appeared to Andreyev, as to James Thomson, a "City of Dreadful Night." His manner is original and he follows the great precept that "in literary works, there should be little room for words and large space for ideas." The same terror of life is expressed in Andreyev's plays *The Life of Man* (1907), *King Hunger*, *Anathema* (1909). He was not a morbid pessimist who derided the misery of mankind, but a mournful humanist. He pities the sufferers and is filled with scorn for those who add nightmare to nightmare. Andreyev's best-known works reflect this attitude: his protest against war, *The Red Laugh* (trans. 1905); against capital punishment, *The Seven That Were Hanged* (trans. 1909), which appeared during the reign of the White Terror in 1909; and the passionate *S. O. S.* (1919), directed against the Red Terror.

Andreyev refused to follow Gorki's example and to recognize the Bolshevik régime, declined the honours offered by the Bolsheviks and fled to Finland. He thus lost the fortune he had accumulated by his writings, and during the last years of his life he once again experienced poverty and even want. *S. O. S.*, one of the most remarkable works of Russian literature, and Andreyev's swan-song, was published in Finland. He died at his villa at Kuokkala, Finland, Sept. 12, 1919. (I. W. S.)

ANDRIA, a town and episcopal see of Apulia, Italy, in the province of Bari; 35m. W. of the town of Bari by steam tramway and 6m. S.E. of Barletta. Pop. (1921) 55,786 (town); 58,895 (commune). It was founded probably about 1046 by Peter, the first Norman count of Andria. It was a favourite residence of the emperor Frederick II., whose second and third wives, Iolanthe and Isabella of England, were buried in the cathedral dedicated to St. Richard, who is believed to have come from England in 492. There are several other fine churches of the 13th century. The Castel del Monte, 9½m. S. of Andria, was constructed by Frederick II., who frequently resided there. Despite its massive and imposing exterior, its details are fine.

ANDRIEU, BERTRAND (1761-1822), French engraver of medals, was born at Bordeaux. He is considered to have restored the art in France, which had declined after the time of Louis XIV.; and during the last 20 years of his life he was entrusted by the French Government with the execution of every work of importance. Many of his medals are figured in the *Medallic History of Napoleon*.

ANDRIEUX, FRANÇOIS GUILLAUME JEAN STANISLAS (1759-1833), French man of letters, was born at Strasbourg on May 6, 1759, and died in Paris on May 9, 1833. He was educated for the bar, and under the Convention was a civil judge in the court of cassation. He became president of the *Tribunal*, but was displaced because of his irreconcilable opposition to the civil code. In his retirement he returned to dramatic writing. He had made a hit in 1788 with *Les Étourdis* and he now produced *Molière avec ses amis* (1804). Among his later plays were *La Comédienne* (1816) and *Lucius Junius Brutus* (1830). As professor of literature at the Collège de France, he maintained the classical tradition and opposed the growing romantic school. In 1829 he became perpetual secretary to the Academy, and worked hard at the completion of the Dictionary.

See also A. H. Taillandier, *Notice sur la vie et les ouvrages d'Andrieux* (1850); Sainte-Beuve, *Portraits littéraires*, vol. i.

ANDRISCUS, "pseudo-Philip," a fuller of Adramyttium, claimed to be a son of Perseus, last king of Macedonia. He seized the Macedonian throne in 149 B.C., after defeating the Roman

praetor, and his conquest of Thessaly and alliance with Carthage made the situation dangerous. In 148 he was defeated by Q. Caecilius Metellus and given up to Rome. After this Macedonia was formally reduced to a province.

See Velleius Paterculus i. 11; Florus ii. 14; Livy, *Epit.* 49, 50, 52; Diod. Sic. xxxii. 9.

ANDROCLES, more correctly ANDROCLUS, a Roman slave, who lived about the time of Tiberius. He is the hero of a story by Aulus Gellius (v. 14), which tells that Androclus had taken refuge from the cruelties of his master in a cave in Africa, when a lion entered the cave and showed him his swollen paw, from which Androclus extracted a large thorn. The grateful animal subsequently recognized him when he had been captured and thrown to the wild beasts in the circus, and, instead of attacking him, began to caress him; he was then set free. (Aelian, *De Nat. An.*, vii. 48.) The story is the subject of the play, *Androcles and the Lion*, by G. Bernard Shaw.

ANDROIDES: see AUTOMATON.

ANDROMACHE, in Greek legend, the daughter of Eëtion, prince of Thebes in Mysia, and wife of Hector (*q.v.*). All her relations perished in or shortly after the taking of the town by Achilles (*Iliad*, vi. 414). After the capture of Troy her son Astyanax (or Scamandrius) was hurled from the battlements (Eurip. *Troades*, 720). When the captives were allotted, Andromache fell to Neoptolemus (Pyrrhus), the son of Achilles, whom she accompanied to Epirus, and to whom she bore three sons. When Neoptolemus was slain at Delphi, he left Andromache and the kingdom to Helenus, the brother of Hector (Virgil, *Aen.* iii. 294). After his death Andromache returned to Asia Minor with her youngest son Pergamus, who there founded a town named after himself.

ANDROMEDA, in Greek legend, the daughter of Cepheus and Cassiopeia (*q.v.*). To satisfy Poseidon, who had been offended, Andromeda, chained to a rock, was exposed to a sea monster. Perseus, returning from having slain the Gorgon, found her, slew the monster, set her free, and married her in spite of Phineus, to whom she had before been promised (Ovid, *Metam.*, v. 1). Andromeda followed her husband to Tiryns in Argos, and became the ancestress of the family of the Perseidae. After her death she was placed by Athena amongst the constellations in the northern sky, near Perseus and Cassiopeia. Sophocles and Euripides (and in modern times Corneille) made the story the subject of tragedies, and its incidents were represented in numerous ancient works of art.

The most famous feature of the astronomical constellation is the Great Andromeda Nebula—the brightest of the spiral nebulae. It can be seen without much difficulty with the naked eye and recognized by its diffuse appearance. It is an "island universe" probably containing millions of stars and of the same general nature as our own stellar system, though apparently of somewhat smaller dimensions. (See NEBULA.) From the brightness of the Cepheid variables in the nebula, Hubble has deduced that its distance is 900,000 light-years. A number of outbursts of Novae (temporary stars) have been observed in the nebula. Nearly all the spiral nebulae are receding from us with large velocities, but the Andromeda nebula is one of the exceptional approaching systems, its velocity in the line of sight being 300 kilometres per second. Photographs show in great detail its beautiful spiral structure; the plane of the spiral is tilted with respect to us, giving the nebula an apparently elongated form.

The double star γ Andromedae is a favourite object for observation with a small telescope on account of the striking contrast of colour of the two components.

The Andromedids are a swarm of meteors which made a notable display on Nov. 27 1872, and provide some of the November meteors year by year; the swarm is believed to be the debris of Biela's comet which was last seen in 1852.

ANDRONICUS I. (COMNENUS), Emperor of the East, son of Isaac, and grandson of Alexius I. Comnenus, was born about the beginning of the 12th century. In 1141 he was taken captive by the Turks (Seljuks) and remained in their hands for a year. On being ransomed he went to Constantinople to the court of his

cousin, the Emperor Manuel, with whom he was a great favourite. Andronicus repeatedly fell into disgrace with the emperor on account of his licentious conduct and his liaisons with different ladies connected with the imperial family. A great part of his life between 1152 and 1180, the date of the death of the Emperor Manuel was spent in hiding in courts in the outlying districts of the empire.

In 1180 the Emperor Manuel died and was succeeded by his son Alexius II., who was under the unpopular guardianship of the Empress Maria. He left his retirement, secured the support of the army and marched upon Constantinople, where his advent was stained by a cruel massacre of the Latin inhabitants. Alexius was compelled to acknowledge him as colleague in the empire, but was soon put to death. Andronicus, now (1183) sole emperor, married Agnes, widow of Alexius II., a child eleven years of age. His short reign was characterized by strong and wise measures. He resolved to suppress many abuses, but, above all things, to check feudalism and limit the power of the nobles. The people, who felt the severity of his laws, at the same time acknowledged their justice, and found themselves protected from the rapacity of their superiors. The aristocrats, however, were infuriated against him, and summoned to their aid William of Sicily. This prince landed in Epirus with a strong force, and marched as far as Thessalonica, which he took and destroyed; but he was shortly afterwards defeated, and compelled to return to Sicily. Andronicus seems then to have resolved to exterminate the aristocracy, and his plans were nearly crowned with success. But in 1185, during his absence from the capital, his lieutenant ordered the arrest and execution of Isaac Angelus, a descendant of the first Alexius. Isaac escaped and took refuge in the church of St. Sophia. He appealed to the populace, and a tumult arose which spread rapidly over the whole city. When Andronicus arrived he found that his power was overthrown, and that Isaac had been proclaimed emperor. Isaac delivered him over to his enemies, and for three days he was exposed to their fury and resentment. At last they hung him up by the feet between two pillars. His dying agonies were shortened by an Italian soldier, who mercifully plunged a sword into his body. He died Sept. 12 1185.

ANDRONICUS II. (PALAEOLOGUS) (1260–1332), eastern Roman emperor, was the elder son of Michael Palaeologus, whom he succeeded in 1282. He allowed the fleet, which his father had organized, to fall into decay; and the empire was thus less able than ever to resist the exacting demands of the rival powers of Venice and Genoa. During his reign the Turks under Osman conquered nearly the whole of Bithynia; and to resist them the emperor called in the aid of Roger di Flor, who commanded a body of Spanish adventurers. The Turks were defeated, but Roger was found to be nearly as formidable an enemy to the imperial power. He was assassinated by Andronicus's son and colleague, the emperor Michael IX., in 1305. His adventurers (known as the Catalan Grand Company) declared war upon Andronicus, and, after devastating Thrace and Macedonia, conquered the duchy of Athens and Thebes. From 1320 onwards the emperor was engaged in war with his grandson, Andronicus. He abdicated in 1328 and died in 1332.

ANDRONICUS III. (1296?–1341), eastern Roman emperor, grandson of Andronicus II. His conduct during youth was so violent that, after the death of his father, Michael, in 1320, his grandfather resolved to deprive him of his right to the crown. Andronicus rebelled; he had a powerful party, and the first period of civil war ended in his being crowned and accepted as colleague by his grandfather (1325). The quarrel broke out again and, notwithstanding the help of the Bulgarians, the older emperor was compelled to abdicate (1328). During his reign Andronicus III. was engaged in constant war, chiefly with the Turks, who greatly extended their conquests. He annexed large regions in Thessaly and Epirus, but they were lost before his death to the rising power of Serbia under Stefan Dušan. He did something for the reorganization of the navy, and recovered Lesbos and Chios from the Genoese. He died on June 15, 1341.

ANDRONICUS OF CYRRHUS, Greek astronomer, flourished about 100 B.C. He built a *horologium* at Athens, the

so-called "tower of the winds," a considerable portion of which still exists. It is octagonal, with figures carved on each side, representing the eight principal winds. A brazen Triton on the summit, with a rod in his hand, turned round by the wind, pointed to the quarter from which it blew. From this model is derived the custom of placing weathercocks on steeples.

ANDRONICUS OF RHODES (c. 70 B.C.), the 11th scholarch of the Peripatetics. He edited the writings of Aristotle and Theophrastus, and wrote paraphrases of Aristotle and commentaries. Two treatises are sometimes erroneously attributed to him, one on the emotions, the other a commentary on Aristotle's *Ethics* (really by Constantine Palaeocappa in the 16th century, or by John Callistus of Thessalonica).

See Susemihl, *Geschichte der griechischen Literatur in der Alexandrinarzeit* ii. 301–305 (Leipzig 1891–92).

ANDROPHAGI, an ancient nation of cannibals placed by Herodotus (iv. 18, 106), who denies that they are Scythians, well to the north of Scythia, probably in the forests between the upper waters of the Dnieper and Don. They were most likely Finns (Samoyed has the same meaning) and perhaps the ancestors of the Mordvinians (q.v.).

ANDROS, SIR EDMUND (1637–1714), English colonial governor in America, was born in London on Dec. 6, 1637, son of Amice Andros, royal bailiff of the island of Guernsey. In 1674 he

SIR EDMUND ANDROS BEING LED A PRISONER THROUGH BOSTON STREETS
The deposition and arrest of Sir Edmund Andros, governor of the "Dominion of New England," by his colonists in 1689, was an early expression of the spirit of independence which less than 100 years later resulted in the American Revolution

was appointed by the duke of York (later James II.) governor of New York and the Jerseys, though his jurisdiction over the Jerseys was disputed, and until his recall in 1681 to meet an unfounded charge of dishonesty and favouritism, he proved himself to be a capable administrator. His imperious disposition, however, made him unpopular among the colonists. In 1686 he became governor, with Boston as his capital, of the "Dominion of New England," into which Massachusetts (including Maine), Plym-

outh, Rhode Island, Connecticut and New Hampshire were consolidated, and in 1688 his jurisdiction was extended over New York and the Jerseys. But his interference with colonial rights and customs aroused resentment, and on April 18, 1689, soon after news of the arrival of William, prince of Orange, in England reached Boston, the colonists deposed and arrested him, and the inter-colonial union was dissolved. Andros was sent to England for trial in 1690, but was immediately released, and from 1692 until 1698 he was governor of Virginia, but was recalled through the agency of the Commissary James Blair with whom he quarrelled. In 1693-94 he was also governor of Maryland. From 1704-06 he was governor of Guernsey. He died in London in Feb. 1714 and was buried at St. Anne's, Soho.

See *The Andros Tracts* (Boston, 1869-72).

ANDROS or **ANDRO**, the most northerly island of the Cyclades, 6m. S.E. of Euboea, and about 2m. N. of Tenos; nearly 25m. long; greatest breadth 10 miles. Pop. about 18,000. It is mountainous, with many fruitful and well-watered valleys. Andros, the capital, on the east coast, contains about 2,000 inhabitants. The ruins of Palaeopolis, the ancient capital, are on the west coast; the town possessed a famous temple, dedicated to Bacchus. The ancient population was mainly Ionian, perhaps with a Thracian admixture. Originally dependent on Eretria, by the 7th century B.C., it sent colonies to Chalcidice (Acanthus, Stageirus, Argilus, Sane). In 480 it supplied ships to Xerxes and was subsequently harried by the Greek fleet. Though enrolled in the Delian League it remained disaffected towards Athens, and revolted in 411. In the Hellenistic period Andros was coveted as a frontier-post by the naval powers of Macedonia and Egypt. In 200 it was captured by a combined Roman, Pergamene and Rhodian fleet, and remained a possession of Pergamum until the bequest of that kingdom to Rome in 133 B.C. Before falling under Turkish rule, Andros was from A.D. 1207 till 1566 governed by the families Zeno and Sommariva under Venetian protection. It is now an eparchy of Greece.

ANDROTION (c. 350 B.C.), Greek orator, was a pupil of Isocrates and a contemporary of Demosthenes. He is known to us chiefly from the speech of Demosthenes, in which he was accused of illegality against Androtion in proposing the usual honour of a crown to the Council of Five Hundred at the expiration of its term of office. Androtion filled several important posts, and during the Social War was appointed extraordinary commissioner to recover certain arrears of taxes. He is said to have gone into exile at Megara, and to have composed an *Atthis*, or annalistic account of Attica from earliest times to his own days (Pausanias vi. 7; x. 8). It is disputed whether the annalist and orator are identical, but an Androtion who wrote on agriculture is certainly a different person.

Professor Gaetano de Sanctis (in *L'Attide di Androzione e un papiro di Oxyrhynchos*, Turin, 1908) attributes to Androtion, the athidographer, a 4th-century historical fragment, discovered by B. P. Grenfell and A. S. Hunt (*Oxyrhynchus Papyri*, vol. v.). Strong arguments against this view were set forth by E. M. Walker in the *Classical Review*, May, 1908.

ANDUJAR, the ancient *Isturgi*, town of Spain, in the province of Jaén; on the right bank of the river Guadalquivir. Pop. (1920) 17,950. Porous jars, called *alcarrazas*, which keep water cool in the hottest weather, are made from a whitish clay found at Andujar.

ANECDOTE, a word originally meaning something not published. It has now two distinct significations. The primary one is something not published, in which sense it has been used to denote either secret histories—Procopius, e.g., gives this as one of the titles of his secret history of Justinian's court—or portions of ancient writers, which have remained long in ms. and are edited for the first time. Of such *anecdota* there are many collections; the earliest was probably L. A. Muratori's, in 1709. In the more general and popular acceptance of the word, however, anecdotes are short accounts of detached interesting particulars. Of such anecdotes the collections are almost infinite. Spence's *Anecdotes*, Horace Walpole's *Anecdotes of English Painting*, and Mrs. Thrale's *Anecdotes of the late Samuel Johnson, LL.D.* are 18th century collections that are still read. One of the best compilations is that made by T. Byerley (d. 1826) and J. Clinton Rob-

ertson (d. 1852) known as the *Percy Anecdotes* (1820-23). A more recent collection is *Literary Anecdotes of the Nineteenth Century*, edited by W. R. Nicoll and T. J. Wise.

ANEL, DOMINIQUE (1679-1730), French surgeon, was celebrated for his successful treatment of *fistula lacrymalis*. While at Genoa he invented the fine-pointed syringe, still known by his name, for use in the operation.

ANEMOMETRY, the measurement of air speed. It is difficult to design instruments to measure accurately the speed of moving air; and although recent research has helped, difficulties still persist, particularly as regards the measurement of low air speeds. The trouble is mainly because direct methods are impracticable, so it is necessary to measure some physical effect arising from the motion. Three such effects have been found suitable—namely, pressure changes associated with the motion; mechanical effects, such as the rotation of certain types of windmills appropriately mounted in the stream; and, lastly, the rate of cooling of a hot body, such as an electrically heated wire, exposed to the current. The first is most important, since a properly designed instrument, suitably inserted in the stream, experiences a pressure, commonly called the velocity head, entirely characteristic of the motion, and measurable on a pressure gauge. If such an instrument is constructed on what are now established principles it may be used without calibration as a standard for measurement of wind speed. This is not true of anemometers which depend on mechanical or electrical effects; these are subject to individual variations and require calibration against a standard instrument of the pressure-tube type.

Pressure-tube anemometers in general consist of two parts; one is common to all types—namely, an open-ended tube facing the air stream. If flow through this tube is prevented, by connecting the other end to a pressure gauge, the pressure at the mouth is found to be equal invariably to the sum of the static pressure and

FIG. 1.—DIAGRAM OF PITOT-STATIC PRESSURE TUBE, USED AS A STANDARD FOR THE MEASUREMENT OF WIND SPEED

The wind speed is calculated from the pressures set up in the two tubes when they are placed in an air current

the velocity head in the stream at that point. The other part of the anemometer varies in detail with different types, but always consists of a second tube with orifices so arranged as to measure either the static pressure in the stream or the static pressure multiplied by a certain coefficient characteristic of the instrument.

We may consider first the case in which the static tube measures accurately the static pressure itself. If then the two tubes of the complete anemometer are connected to opposite sides of the same differential pressure gauge, the static pressure portion of the pressure transmitted by the facing or "total head" tube will be

balanced by the pressure transmitted from the static tube, and the resultant reading on the gauge will be the velocity head p , which is related to the speed of the air-stream V by the equation

$$p = 0.5 \rho V^2 \quad (1)$$

where p is measured as force per unit area and ρ is the air density (mass per unit volume), calculable in any given case from knowledge of the temperature and pressure of the air.

An instrument, whose differential readings measure the velocity-head to an accuracy of about 0.1% is shown in fig. 1. The two tubes are here arranged concentrically, the inner, or Pitot tube (so called after Pitot, who was the first to suggest the use of pressure-tube anemometers), measuring the sum of the velocity and static heads—that is the “total” head, whilst the outer one measures the static pressure at the series of small orifices around its periphery as shown on the diagram. Such an instrument forms a convenient standard to which the readings of other types of anemometers may be referred.

In pressure-tube instruments of the second type, in which the static side does not indicate the true static pressure, the differential pressure p_1 is usually given by an equation of the form

$$p_1 = k \rho v^2 \quad (2)$$

where k is now a coefficient whose magnitude is in general greater than 0.5 and may vary with the wind speed. In the Dines pressure-tube, much used in meteorological work, the total head tube is mounted so that it is free to rotate about a vertical axis, and is equipped with a weathercock-vane which always points the tube into the wind. A vertical tube, pierced with a number of small holes past which the wind streams, forms the static side, the constant k in equation (2) for this instrument being about 0.75. The pressures are usually transmitted to a recording float-manometer, in which the float moves vertically by an amount corresponding to the applied pressure difference. The motion of the float is communicated to a pen which marks on a chart attached to the surface of a cylindrical drum driven by a clock, and making as a rule one complete revolution in 24 hours. Continuous records of wind speed extending over this period are thus obtained on one chart.

Many mechanical devices for measuring air speeds have been proposed, but only the Robinson cup anemometer and the vane anemometer now survive to any marked degree. The former (see fig. 2) consists essentially of four hemispherical cups carried with their bases vertical, at the outer ends of four light arms forming a 90° cross in a horizontal plane, and attached to a central sleeve free to rotate about a vertical axis. Opposite cups are arranged so that the concave side of one member of the pair is presented to the air current at the same time as the convex side of the other. Hence, since the aerodynamic force on a cup with its concave face presented to the wind is greater than when the wind is blowing on its convex face, rotation will ensue at a rate depending on the wind speed. The cups are connected by gearing to an indicating mechanism which may either show revolutions, or, as is almost universal practice, units of distance travelled by the wind. In the latter case the distance travelled by the wind for one revolution of the cups is deduced from experience with other instruments of similar type, and the gearing ratio is adjusted to suit this relationship. Under steady conditions, then, the wind speed is obtained by observing, with a stop watch, the motion of the indicating mechanism in a given time.

The ratio of wind speed to linear speed of the centres of the cups is termed the factor of the anemometer. Experimental evidence indicates that the value of this factor depends on the dimensions of the instrument and also on the wind speed, so that

even for any particular instrument the factor is not constant at all speeds. These anemometers must be calibrated in winds of known speeds for accurate work. From tests on many such instruments of different sizes it appears that the factor may vary from about 2.2 at the high wind speeds to possibly a little over three at low speeds. A convenient form of cup anemometer has an electric generator attached to the cup shaft and driven by it. The E.M.F. generated thus depends on the rate of rotation of the cups, and can therefore be used as a measure of the wind speed, the relation between these two quantities being determined by test. An indicating voltmeter, connected to the generator, can then be calibrated to read wind speed directly on a scale. Alternatively, by the use of a recording voltmeter, continuous records of wind speed can be obtained. This form of instrument gives an instantaneous reading of wind speed, without the necessity for a stop watch, and also readings can be taken at a distance from the anemometer cups themselves. Obviously, the latter feature is often one of considerable importance, particularly in meteorological work, which is the main field of application of the cup anemometer, since its readings are not affected by changes of wind direction in the horizontal plane. Other forms of distant-recording mechanism have also been devised.

The vane anemometer consists of light flat vanes attached to radial arms mounted on a common spindle which rotates in two jewelled bearings. Eight vanes are usually employed; they are inclined at an angle to the axis of the spindle, which is set along the wind direction when the instrument is in use, and the wind forces acting on the vanes cause the spindle to rotate at a rate depending, in any given case, on the air speed. As in the cup anemometer, the motion of the spindle is communicated by a gear train to a pointer, or, more usually, to a number of pointers moving over dials graduated directly in feet. Experience has taught the makers how to proportion the various dimensions and gear ratios so that the number of feet indicated on the dials in unit time is approximately equal to the distance traversed by the wind in the same time, *i.e.*, to the wind speed. Instruments of this type are mainly of value for measuring air speeds in large ducts or ventilating shafts. They are particularly useful for measuring low speeds where the pressures to be measured with pressure-tube instruments are so small as to necessitate the use of extremely sensitive manometers.

Vane anemometers of normal design can be used over a range of wind speeds from about five to 50 feet per second. For higher speeds, up to 100 feet per second, special instruments are made which are either of heavier construction or, alternatively, incorporate a device by means of which the quantity of air actually passing through the vanes can be reduced. Vane anemometers of specially light construction can also be obtained to measure speeds of less than five feet per second, the lower limit of speed that will cause steady rotation of the vanes being the order of 0.5 feet per second. All instruments need calibration in a wind whose speed can be controlled and adjusted to known values, for it is not possible to predict accurately the readings of a mechanical anemometer from a knowledge of its dimensions only.

In the absence of mechanical friction due to weight of moving parts and to gearing, readings of both cup and vane anemometers would depend only on the wind speed, and so would be independent of changes of air density. In most cases these frictional couples will be small compared with the aerodynamic driving torque, and no attention need therefore normally be paid to changes in air density. If, however, the changes of density are large—more than about 5%—the readings should be corrected. The simplest method is, perhaps, to alter both the ordinate and the abscissa of any point on the original calibration curve of the instrument in the ratio $\sqrt{\frac{\rho_0}{\rho_1}}$, where ρ_0 is the air density at the time of

calibration and ρ_1 is the new air density. In this way a point on the calibration curve for density ρ_1 is obtained, and by repeating this process for a number of points on the original curve the curve for density ρ_1 can be drawn.

As regards the effect of inclination to the wind direction, it has been shown that the axis of the vane circle may be out of align-

BY COURTESY OF NEGRETTI AND ZAMBRA

FIG. 2.—A ROBINSON CUP ANEMOMETER

The velocity of the wind is transmitted to the dial by the revolution of the four metal cups. The dial is usually graduated in miles per hour

ment with the wind by an angle approaching 20° before the readings of the anemometer are in error by more than about two or three per cent. A fluctuating wind speed is another source of error, for the vane anemometer then tends to indicate more than the true mean speed, but errors will be negligible unless fluctuations are very violent. If maximum and minimum air speeds are respectively 50% above and below mean speed the error on the mean speed indicated by the instrument may be of the order of 10 or 15% high. It can be shown, however, that the error depends on the square of the amplitude of the fluctuations so it decreases rapidly as the wind becomes steadier. An amplitude of 50% on either side of the mean represents a very unsteady air stream.

Electrical or hot wire anemometers have not been much used because of the elaborate apparatus and manipulation involved, but certain types have been developed for industrial application. They may yield excellent laboratory results, and are, in particular, well suited to the measurement of low air speeds. (See also AERIAL NAVIGATION.)

ANEMONE or WIND-FLOWER, a genus of the buttercup family (Ranunculaceae), containing about 120 species in the temperate zones. *Anemone nemorosa*, wood anemone, and *A. Pulsatilla*, Pasque-flower, occur in Britain. The plants are perennial herbs with an underground rootstock and radical, deeply cut, leaves. The elongated flower stem bears white, red, blue or, rarely, yellow flowers; there is an involucre of three leaflets below each flower. The fruits often bear long hairy styles for distribution by the wind. Many are favourite garden plants; among the best known is *Anemone coronaria*, the poppy anemone, a tuberous-rooted plant, with divided leaves, and large showy poppy-like blossoms on stalks from 6 to 9 in. high; the flowers are scarlet, crimson, blue, purple or white. There are also double-flowered varieties. It is enriched with manure. The genus contains many other spring-blooming plants, of which *A. hortensis* and *A. fulgens* have less divided leaves and rosy-purple or scarlet flowers. Another set is represented by the Pasque-flower whose violet blossoms have the outer surface hairy; these prefer a calcareous soil. The splendid *A. japonica*, and its white variety, Honorine Joubert, are fine autumn-blooming perennials; they grow well in light soil. A group of dwarf species, represented by the native British *A. nemorosa* and *A. apennina*, are beautiful spring flowers.

In the United States and Canada there are about 20 native species, with representatives in all regions from arctic America and Alaska south to Florida, Texas and California. Among these are some of the most attractive North American wild flowers. Noteworthy species are the American wood anemone (*A. quinquefolia*), of low woods from Nova Scotia to Minnesota south to Georgia, very similar to the wood anemone (*A. nemorosa*) of Great Britain; the Canada wind-flower (*A. canadensis*), with large white flowers, found in low grounds from Labrador to Saskatchewan and southward to Maryland and Colorado; the tall wind-flower or thimble-weed (*A. virginiana*), with greenish-white flowers, growing in woods from Nova Scotia to Alberta and south to South Carolina and Arkansas; the long-fruited wind-flower (*A. cylindrica*), a silky-hairy plant native to open grounds from New Brunswick to British Columbia and south in the Rocky Mountains to New Mexico; the Carolina wind-flower (*A. caroliniana*), with purple or white flowers, growing in open grounds from Florida to Texas and northward to Wisconsin and South Dakota; the mountain wind-flower (*A. trifolia*), with large white flowers, often growing with the lily-of-the-valley, native to the Appalachian region; the red wind-flower (*A. hudsoniana*), silky-hairy with red or greenish flowers, found from New Brunswick to Minnesota; the northern wind-flower (*A. parviflora*), a delicate plant with white flowers, ranging from Labrador to Alaska and southward in the Rocky Mountains to Colorado; and Richardson's wind-flower (*A. Richardsonii*), a slender boreal dwarf with yellow flowers, found from Labrador to Hudson bay and widely in arctic America.

To the division *Pulsatilla* belong the American pasque-flowers (*A. patens*, var. *Wolfgangiana*), with handsome blue, purple, or white flowers, a very early spring bloomer on dry prairies and high plains from Illinois to British Columbia and Alaska and south-

ward to Utah and Texas; and the western pasque-flower (*A. occidentalis*), found on gravelly hills and mountain slopes from California to Alaska and eastward to Alberta and Montana. The former is the floral emblem or State flower of South Dakota.

ANENCLETUS or **ANACLETUS**, second bishop of Rome. About the 4th century he is treated in the catalogues as two persons—Anacletus and Cletus. According to the catalogues he occupied the papal chair for 12 years (c. 77–88).

ANERIO, FELICE (1560–1614), composer. He studied under Nanino, and succeeded Palestrina in 1594 as composer to the papal chapel. Masses and motets of his are printed in Proske's *Musica Divina* and other modern anthologies. The 12-part *Stabat Mater* in vol. vii. of Palestrina's works may have been by Felice Anerio.

His brother, GIOVANNI FRANCESCO, also a composer, was born about 1567, and died 1620.

ANEROID BAROMETER. This instrument consists essentially of a vacuum chamber, two opposite walls of which are thin metal membranes, which respond elastically to any variation of pressure on their outer faces, their movement being controlled by a spring and communicated to the indicating needle. An instrument depending on a similar principle is the Bourdon pressure gauge (q.v.). The aneroid barometer is not so accurate as the mercury barometer, but it is often employed when the use of the latter would be inconvenient. (See BAROMETER.)

ANET, town of north France, in the department of Eure-et-Loir, situated between the rivers Eure and Vègre, 10 m. N.E. of Dreux by rail. Pop. (1926) 1,205. It possesses the remains of a magnificent castle, built in the middle of the 16th century by Henry II. for Diana of Poitiers. Near it is the plain of Ivry, where Henry IV. defeated the armies of the League in 1590.

ANEURIN, a British (Welsh) bard, author of the *Gododin*, flourished at the beginning of the 7th century. He is said to have been the son of Caw-ab-Geraint, a chief of the Gododin, who had their home on the sea-coast to the south of the Firth of Forth. In some of the mss. which give the names of Caw's sons, the name of Gildas appears, but where the name of Aneurin appears that of Gildas does not. It has therefore been assumed that the British historian Gildas and the bard Aneurin were one and the same person, though the internal evidence of their works appears to confute this. Thomas Stephens, the editor and translator of the *Gododin* epic, thinks that Aneurin may have been a son of Gildas.

Aneurin seems to have studied at St. Cadoc's College, Llan-cavan, and to have acted both as priest and bard at the Battle of Cattraeth described in his epic. This fight is identified by Stephens with the battle of Degstan, assigned by the *Saxon Chronicle* to the year 603. Aneurin was taken prisoner after the battle. On his release he returned to Wales and became a friend of Taliesin. In his old age he returned to the north and lived with his brother in Galloway. The *Gododin* is vague in its language and in its description of events. It relates the defeat of the Britons of Strathclyde at the hands of the Saxon invader at the battle of Cattraeth.

See the versions of the *Gododin* in Skene's *Four Ancient Books of Wales* (1866), and in the edition by Thomas Stephens published by the Cymmrodorion Society (1888).

ANEURYSM or **ANEURISM**, a cavity or sac which communicates with the interior of an artery and contains blood. The walls of the cavity are formed partly by the dilated artery and partly by the tissues around that vessel. The dilatation of the artery is due to local degeneration or injury of the inner coats of the vessel. In a rare variety (dissecting aneurysm) the blood is contained at first in the region of the middle coat of the artery which may be opened up from arch of the aorta to the iliac vessels. Aneurysms may be *spontaneous* or *traumatic*. The man who has chronic inflammation of a large artery, the result, for instance, of syphilis, gout, arduous straining work, or kidney-disease, and whose artery yields under cardiac pressure, has a *spontaneous* aneurysm; the barman or window-cleaner, who has cut his radial artery, the soldier whose brachial or femoral artery has been bruised by a rifle bullet or grazed by a bayonet, and the boy whose

naked foot is pierced by a sharp nail, are apt to be the subjects of *traumatic aneurysm*. In saccular aneurysms bulging on one side of an artery the blood may be induced to coagulate, or may of itself deposit layer upon layer of pale clot, until the sac is obliterated, and the aneurysm is cured. But in those aneurysms which are *fusiform* dilatations of the vessel there is but slight chance of such cure, for the blood sweeps evenly through it without staying to deposit clot or laminated fibrine.

In the treatment of aneurysm the aim is generally to lower the blood pressure by absolute rest and moderated diet, but a cure is rarely effected except by operation. Speaking generally, if an aneurysm can be dealt with surgically the sooner that the artery is tied the better. Other measures are too apt to prove painful, dangerous, ineffectual and disappointing. For aneurysm of the great arteries in the chest or abdomen (which cannot be dealt with by operation) treatment is unsatisfactory and consists, mainly, in measures designed to avoid strain. Usually such an aneurysm ends life by rupture.

ANFRACTUOSITY, twisting and turning, circuitousness. Usually employed in the plural to denote winding channels such as occur in the depths of the sea, mountains, or the fissures (*sulci*) separating the convolutions of the brain.

ANGARIA, the term used to denote the postal system adopted by the Roman imperial government from the ancient Persians, among whom, according to Xenophon, it was established by Cyrus the Great. The word is derived from the Greek form of a word, originally Babylonian, meaning "mounted courier." Couriers on horseback were posted at certain stages along the chief roads of the empire, for the transmission of royal dispatches by night and day in all weathers. In the Roman system the supply of horses and their maintenance was a compulsory duty from which the emperor alone could grant exemption. The word came to mean generally "compulsory service." So *angaria*, in mediaeval Latin, and the rare English derivative "angariation," came to mean any service which was forcibly demanded, and oppression in general. See Xenophon, *Cyrop.*, viii. 6; Herodotus viii. 98.

ANGARY, RIGHT OF. The term "angary" is derived from a Persian word signifying "a messenger" upon the royal service who was entitled to requisition means of transport. This custom was adopted in Greece in the 3rd century B.C. and passed to Rome. In *Corpus Juris*, *angaria* denotes requisition of horses, wagons, etc., in connection with the *cursus publicus*. It was extended to the requisition of neutral shipping for the transport of troops. The right survived throughout mediaeval Europe as a royal prerogative, and was exercised for purposes of public and military transport, but the term was not generally applied to ships till the 17th century, when it became a rule of international law. In the 16th century the Venetians requisitioned a Genoese vessel and its cargo of corn to meet a food shortage, and its legality *ob publicam utilitatem* was approved. Requisition of neutral shipping became fairly general in the 18th century, but was exceptional in the 19th, although the right was expressly recognized in a number of treaties, whether in time of peace or war, in case of public necessity, subject of course to adequate compensation.

In the World War, the Italian Government, whilst still neutral, requisitioned, in 1915, 34 German merchantmen lying in Italian ports. Germany made no protest, but when Portugal requisitioned, in 1916, 72 German vessels lying in Portuguese ports, Germany made it a *casus belli* and declared war on that power. In 1917 Brazil, having revoked her proclamation of neutrality, and prior to her declaration of war, requisitioned 42 German merchantmen. At the same time Great Britain and the United States, after fruitless negotiations with Holland, requisitioned Dutch shipping to the amount of 1,000,000 tons lying in their ports "in exercise of the right of angary," one of the attributes of territorial sovereignty. In 1918 Spain requisitioned about 90 German vessels lying in Spanish ports as an act indispensable for her existence, and in view of the sinking of her own merchantmen by German submarines declared that no compensation was due. The United States also requisitioned a number of Norwegian ships under construction in American yards.

Consequently the right of angary, that is; the right of a State,

whether belligerent or neutral, whether in time of peace or war, to requisition ships and goods situate in its territory, subject to adequate compensation, both by constitutional and international law, may be said to be firmly established. This right must be distinguished from that of requisition by a belligerent in territory occupied by him, which is based on military necessity under the laws of war.

(H. H. L. B.)

ANGEL, a term used in the vocabulary of monotheistic religions to describe a personal being intermediate in nature, status, and powers, between God and man. It may be conjectured that in most instances a belief in such beings is an attempt to retain the subordinate gods and spirits of a polytheistic or an animistic faith which preceded the development of monotheism. Of the four great monotheistic religions, Islam and Christianity accepted current Jewish ideas of angels, while in Zoroastrianism they are clearly either degraded gods or personified qualities and abstractions.

The religion of the Old Testament recognized many such inferior superhuman beings. Whilst it was strictly monolatrous, and recognized Yahweh alone as an object of worship for Israel, it conceived of Him as dwelling in royal state, surrounded by attendants and servants (*cf.* I Kings xxii. 19; Job i. 6, ii. 1; Ps. xxix. 1). These are called "sons of God" (*bēnē ʾēlōhīm* or *ʾelīm*), and in Gen. vi. the origin of giants is ascribed to unions between such beings and mortal women. But Yahweh has other classes of beings at his orders and under his control; such are the "Cherubims" of Gen. iii. 24; Ez. ix.—apparently pictured in some such form as the divine or semi-divine winged bulls of Assyrian sculpture, the "seraphim" of Isaiah's vision—flaming six-winged serpents, or the numerous "men" who act as Yahweh's agents in

the visions of Zechariah and Ezekiel and elsewhere. The "hosts" referred to in the phrase "Yahweh of Hosts" may also belong to this class.

The word "angel" (Heb. *mal'āk*), however, is seldom applied to such beings as these. The following is a list of passages in which it thus occurs, doubtful text or interpretation being indicated by an asterisk: Gen. xix. 1,* 15*; xxviii. 12*; xxxii. 1; Job iv. 18; Ps. lxxviii. 49*; xci. 11; ciii. 20; civ. 4; cxlviii. 2; Dan. iii. 28; vi. 22. The term is used in a peculiar sense in Zechariah of the prophetic spirit which gave to the prophet the sense of a dual personality—the "God within" him. Elsewhere the phrase Angel of Yahweh is employed to indicate the very presence of Yahweh—indeed the term is practically interchangeable with "presence." Its appearance is probably due to a growing feeling that to speak of Yahweh as coming in ordinary human form was unworthy of his majesty. As men began to outgrow the old anthropomorphic ideas they felt their way towards

AFTER A MOSAIC IN THE CHURCH OF SANT' APOLLINARE IN CLASSE FUORI, RAVENNA, ITALY

MICHAEL THE ARCHANGEL. IN CHRISTIAN THEOLOGY THE LEADER OF THE HEAVENLY HOST

a conception which did not picture the whole of the personality of Yahweh to appear on earth, but yet insisted that it was really He and no other who came into human life. Thus the "angel" who appeared to Manoh and his wife (Jud. xiii.) accepts the sacrifice, and is in truth Yahweh Himself.

During the exile and the three centuries which followed the return, the thought of Israel was greatly influenced by the conceptions of the Gentile world, particularly, it seems, by those of Persia. We certainly find in the late Persian period and after the age of Alexander, that angels, in the modern popular sense of

the term, play a much larger part in the realm of Jewish ideas. In the Book of Daniel each nation has its own guardian angel, commonly called "prince"; e.g. the guardian angels of Persia and Greece are mentioned in x. 20, and Michael, guardian of Israel, in vv. 13, 21. From this time onwards angels play a prominent part in all Jewish religious writings. Thus we find Raphael as one of the leading characters in the Book of Tobit, and the Enoch literature—to say nothing of other apocalyptic books of this period—is full of angels, good and bad.

With the growth of a belief in good angels there sprang up also a theory of wicked angels, demons, and the like. A number of different lines of thought converge here, of which two may be regarded as the most important. One of these is the belief in the effect of a "spirit" on man. Any abnormal psychological state was thought in early times to be due to the "breath" of God, a new life-force which entered into a man and changed him. To this source were ascribed the prophetic "ecstasy" and other phenomena which, to-day, might be classed as insanity or even epilepsy. Obviously the effect produced was sometimes evil, and though in primitive times men did not hesitate to ascribe even moral evil to Yahweh, yet as the doctrine of his moral goodness grew under the influence of prophetic teaching, it clearly became necessary to introduce another source. Hence arose a belief in wicked angels, "unclean spirits," and similar beings—a spiritual army hostile to God, as the good angels were His servants and messengers.

The other line of development is that of Satan. This person appears in the Old Testament—particularly in Zechariah and Job—as one of the servants of Yahweh, or rather, an important official of His court. It was the business of the Satan (the word in the O.T. is not a proper name) to detect evil in men and to charge them before Yahweh with their sin, actual or potential. In order to test them, he was compelled to "tempt" them, and when once the thought of an arch-enemy of God and man had been observed in the Persian Ahriman, it was easy for the "tempter" to pass from the side of God to that opposed to Him. Thus there grew up the conception of the Devil, supported by a hierarchy of sin, standing over against the divine court and kingdom. (See DEVIL.) (W. H. BE.; T. H. R.)

ANGEL, a gold coin, first used in France (*angelot*, *ange*) in 1340, and introduced into England by Edward IV. in 1465 as a new issue of the "noble," and so at first called the "angel-noble." It varied in value between that period and the time of Charles I. (when it was last coined) from 6s. 8d. to 10s. The name was derived from the representation it bore of St. Michael and the dragon. The angel was the coin given to those who came to be touched for the disease known as king's evil; after it was no longer coined, medals, called touch-pieces, with the same device, were given instead.

ANGEL-FISH, the popular name for several widely differing species of fishes, including (a) *Squatina squatina*, also called the monk fish, an Elasmobranch allied to the sharks and found in tropical and sub-tropical seas, including the Mediterranean. It takes its name from the large wing-like pectoral fins and reaches a length of 4 feet. (b) In Bermuda, Chaetodont fishes of the genus *Holocanthus*, especially *H. ciliaris*; these fishes are laterally compressed and brilliantly coloured. They haunt coral reefs. *H. ciliaris* may reach a weight of 4 lb. and is delicious eating.

Various species of *Holocanthus* occur on the west coast of tropical America from Cape San Lucas to the Galapagos islands, in the East Indies, Japan and Polynesia. In this same family (*Chaetodontidae*) the American genus *Pomacanthus* is also known as the angel fish. *Chaetodipterus faber*, sometimes called spade fish, is also known as the angel fish. It occurs from Cape Cod to Rio de Janeiro. A very similar species occurs on the west

coast of Mexico. Certain varieties of porgy are also given this name and constitute a favourite dish along the south-east shores of the United States.

ANGELICA, a genus of plants of the family Umbelliferae, represented in Britain by one species, *A. sylvestris*, a tall perennial herb with large bipinnate leaves and large compound umbels of white or purple flowers. The name Angelica is popularly given to *Angelica (Archangelica) officinalis*, the tender shoots of which are used in making certain kinds of aromatic sweetmeats. In the Faroe islands and in Iceland, where the plant grows abundantly, *A. officinalis* has long been used as a vegetable, though in recent years angelica gardens have been more or less replaced by cabbage gardens.

Angelica balsam is obtained by extracting the roots with alcohol, evaporating and extracting the residue with ether.

ANGELICO, FRA (1387–1455), Italian painter. Il Beato Fra Giovanni Angelico da Fiesole is the name given to a painter-friar of the Florentine state in the 15th century. His baptismal name was Guido, Giovanni being only his name in religion. He was born at Vicchio, Tuscany, of unknown but seemingly well-to-do parentage, in 1387 (not 1390, as sometimes stated); in 1407 he became a novice in the convent of S. Domenico at Fiesole, and in 1408 he took the vows and entered the Dominican order. Whether he had previously been a painter by profession is not certain, but probable. The painter named Lorenzo Monaco may have contributed to his art training, and the influence of the Sienese school is plainly discernible in his work. According to Vasari, the first paintings of this artist were in the Certosa of Florence; none exists there now.

His earliest extant performances, in considerable number, are at Cortona, where he was sent during his novitiate, and here apparently he spent the early years of his monastic life. His first works executed in fresco were probably those, now destroyed, which he painted in the convent of S. Domenico in this city; as a fresco-painter, he may have worked under or as a follower of Gherardo Starnina. From 1418 to 1436, he was back at Fiesole; in 1436 he was transferred to the Dominican convent of S. Marco in Florence, and in 1438 undertook to paint the altar-piece for the choir, followed by many other works; he may have studied about this time the renowned frescoes in the Brancacci chapel in the Florentine church of the Carmine and also the paintings of Orcagna. In or about 1446 he was invited by the Pope, Eugenius IV., to Rome. If the story (first told by Vasari) is true—that the archbishopric of Florence had been offered to himself, and by him declined on the ground of his inaptitude—Eugenius, and not (as stated by Vasari) his successor Nicholas V., must have been the Pope who made the offer to Fra Giovanni, for Nicholas only succeeded in 1447. Certain it is that Angelico was staying in Rome in the first half of 1447; and he painted in the Vatican the Cappella del Sacramento, which was afterwards demolished by Paul III. In June 1447 he proceeded to Orvieto, to paint in the Cappella Nuova of the cathedral, with the co-operation of his pupil Benozzo Gozzoli. He afterwards returned to Rome to paint the chapel of Nicholas V. In this capital he died in 1455, and he lies buried in the church of the Minerva. He was beatified at a date unknown.

Fra Giovanni led a holy and self-denying life, shunning all advancement, and was a brother to the poor; no man ever saw him angered. He painted with unceasing diligence, treating none but sacred subjects; he never retouched or altered his work. He was wont to say that he who illustrates the acts of Christ should be with Christ. It is said that he never handled a brush without fervent prayer and he wept when he painted a Crucifixion. The Last Judgment and the Annunciation were two of the subjects he most frequently treated.

Bearing in mind the details already given as to the dates of Fra Giovanni's sojournings in various localities, the reader will be able to trace approximately the sequence of his works. In Florence, in the convent of S. Marco (now converted into a national museum) is a series of frescoes beginning towards 1443, all of which are later than the altar-piece which Angelico painted (as before mentioned) for the choir connected with this convent, and which is now in the academy of Florence. It represents the Virgin

with SS. Cosmas and Damian (the patrons of the Medici family), Dominic, Peter, Francis, Mark, John the Evangelist and Stephen; the pediment illustrated the lives of Cosmas and Damian, but it has long been severed from the main subject. In the Uffizi gallery is an altar-piece, the Virgin (life-sized), enthroned with the Infant and 12 angels. In S. Domenico, Fiesole, there are a few frescoes, less fine than those in S. Marco; also an altar-piece in tempera of the Virgin and Child, now much destroyed. The subject which originally formed the predella of this picture has, since 1860, been in the National Gallery, London. The subject is a Glory, Christ with the banner of the Resurrection, and a multitude of saints, including, at the extremities, the saints or beati of the Dominican order; here are no fewer than 266 figures or portions of figures, many of them having names inscribed. This predella was highly lauded by Vasari; still more highly another picture which used to form an altar-piece in Fiesole, and is now in the Louvre—the "Coronation of the Virgin," with eight predella subjects of the miracles of St. Dominic. For the church of Santa Trinita, Florence, Angelico executed a "Deposition from the Cross" and for the church of the Angeli, a "Last Judgment," both now in the Florentine academy; for S. Maria Novella, a "Coronation of the Virgin," with a predella in three sections, now in the Uffizi—this again is one of his masterpieces. In Orvieto cathedral he painted three triangular divisions of the ceiling, all now much repainted and damaged. In Rome, in the Chapel of Nicholas V., he painted the acts of SS. Stephen and Lawrence, also various figures of saints, and on the ceiling the four evangelists. These works of the painter's advanced age, which have suffered somewhat from restorations, show vigour superior to that of his youth, along with a more adequate treatment of the architectural perspectives. It has often been said that he frequently practised as an illuminator; illuminations executed by Giovanni's brother, Benedetto, also a Dominican, who died in 1448, have probably been ascribed to the more famous artist. Benedetto may perhaps have assisted Giovanni in the frescoes at S. Marco, but nothing of the kind is distinctly traceable. A folio series of engravings from these paintings, was published in Florence in 1852. Along with Gozzoli already mentioned, Zanobi Strozzi and Gentile da Fabriano are named as pupils of the Beato.

For an appreciation of Fra Angelico's art we may quote Sir Charles Holmes (*The National Gallery, Italian Schools*): "One very great colourist, Fra Angelico, arrives before Masaccio, and outlives him. The legend of his saintly life, the happy serenity and simplicity of his temper, tend to distract our attention from his greatness as an artist. Not only does he possess a mastery of design which enables him to treat a large variety of subjects with almost invariable success, but when his theme gives him the necessary scope he attains, as in his "Transfiguration" at Florence, to a power and sublimity which have never been surpassed. He has much of Giotto's power of making his figures seem living and substantial. But above all, he is one of the world's great colourists, and the single painting by his hand which we possess in London will enable us to understand this side of his art in some measure. His other claims to greatness can be estimated only in Florence."

ANGELL, GEORGE THORNDIKE (1823–1909), American philanthropist, was born at Southbridge (Mass.), on June 5, 1823. He graduated at Dartmouth in 1846, studied law at the Harvard Law school, and in 1851 was admitted to the bar in Boston, where he practised for many years. In 1868 he founded and became president of the Massachusetts Society for the Prevention of Cruelty to Animals, in the same year establishing and becoming editor of *Our Dumb Animals*, a journal for the promotion of organized effort in securing the humane treatment of animals. In 1882 he initiated the movement for the establishment of Bands of Mercy (for the promotion of humane treatment of animals), of which in 1908 there were more than 72,000 in active existence. In 1889 he founded and became president of the American Humane Education Society. He became well known as a

criminologist and also as an advocate of laws for the safeguarding of the public health. He died at Boston March 16, 1909.

ANGELL, JAMES BURRILL (1829–1916), American educationalist and diplomat, was born in Scituate, R.I., on Jan. 7, 1829. He graduated in 1849 at Brown university, at which, after travel in Europe, he was professor of modern languages and literature in 1853–60. In 1860–66 he was editor of the Providence *Daily Journal*. From 1866 to 1870 he was president of the University of Vermont. In 1871 he became president of the University of Michigan, serving until 1909, when he was made president emeritus. Under his administration the institution was brought to high rank among American universities. He was United States minister to China in 1880–81, and to Turkey in 1897–98. In 1887 he was a member of the Anglo-American international commission on Canadian fisheries. Besides numerous contributions to periodicals, he published *Progress in International Law* (1875), the article "Diplomacy in the United States" in the *Narrative and Critical History of America* (1888), *Reminiscences* (1912) and *Selected Addresses* (1912). He died at Ann Arbor, Mich., on April 1, 1916.

ANGELL, JAMES ROWLAND (1869–), American educationalist, was born at Burlington, Vt., May 8 1869. He was a son of James Burrill Angell (1829–1916), president of the University of Michigan (1871–1909), president emeritus, and afterwards minister to China and Turkey. He was educated at the Universities of Michigan and Harvard, and spent a year in Europe, chiefly at the Universities of Berlin and Halle. In 1893 he was appointed instructor in philosophy at the University of Minnesota. In 1894 he was called to the University of Chicago as assistant professor of psychology and, after 1905, was professor and head of the department. He was dean of the university faculties after 1911, and acting president during 1918–19. In 1906 he was elected president of the American Psychological Association, in 1914 exchange professor at the Sorbonne, and in 1915 special lecturer at Columbia university. In 1921, on the resignation of Arthur T. Hadley (*q.v.*), he was elected president of Yale university. His works include: *Psychology* (1904; rev. ed., 1908); *Chapters from Modern Psychology* (1911); and *An Introduction to Psychology* (1918).

ANGELUS, a Roman Catholic devotion in memory of the Annunciation. It consists of three texts (beginning "Angelus Domini nuntiavit Mariae," hence the name), with three Ave Marias and a concluding versicle, response and prayer. It is recited three times daily, about 6 A.M., noon and 6 P.M., when the Angelus bell is rung. In a simpler form the devotion can be traced back (as an evening observance) to 1307.

See H. Thurston in *The Catholic Encyclopedia*.

ANGELUS SILESII (1624–1677), German religious poet, was born in 1624 at Breslau, and died there on July 9, 1677. His family name was JOHANN SCHEFFLER, but he is generally known by the pseudonym Angelus Silesius, under which he published his poems and which marks the country of his birth. Brought up a Lutheran, and at first physician to the duke of Württemberg-Oels, he joined in 1652 the Roman Catholic Church, and in 1661 took orders as a priest and became coadjutor to the prince bishop of Breslau. In 1657 Silesius published under the title *Heilige Seelenlust, oder geistliche Hirtenlieder der in ihren Jesum verliebten Psyche* a collection of 205 hymns, the best of which have been adopted in the German Protestant hymnal. His most important work is *Geistreiche Sinn und Schlussreime* (1657), afterwards called *Cherubinischer Wandersmann* (1674). This is a collection of "Reimsprüche" or rhymed distichs embodying a mystical pantheism drawn mainly from the writings of Jakob Böhme and his followers.

BIBLIOGRAPHY.—A complete edition of Scheffler's works (*Sämtliche poetische Werke*) was published by D. A. Rosenthal (Regensburg, 1862). Both the *Cherubinischer Wandersmann* and *Heilige Seelenlust* have been republished by G. Ellinger (1895 and 1901), and a selection from the former work by O. E. Hartleben (1896). For further notices of Silesius' life and work, see Hoffmann von Fallersleben in *Weimarisches Jahrbuch I.* (Hanover, 1854); A. Kahlert, *Angelus Silesius* (1853); C. Seltmann, *Angelus Silesius und seine Mystik* (1896), and a biog. by H. Mahn (Dresden, 1896).

ANGER is an emotion consisting of antagonistic, displeased, attacking feelings toward an offending person or thing. Some psychologists have attempted to distinguish anger from rage by supposing that true anger occurs only when the sex or love emotion is opposed, as in the sex combats of rival males among animals and human beings. It is said that anger, at such times, contains a self-abandonment never found in the rage accompanying struggles for food. In popular parlance, however, anger and rage are practically synonymous. This emotion has been found in the behaviour of very young infants (J. B. Watson). It occurs when the baby's spontaneous movements are hampered or interfered with by the experimenter, and is expressed by crying, holding the breath and thrashing wildly about with arms and legs. Experiments on animals (W. B. Cannon) also have shown that anger or rage causes increased secretion of adrenalin, with heightened blood pressure, dilation of the pupils of the eyes and increase of blood sugar. Experiments on adult human beings (W. M. Marston) have shown that anger is accompanied by increased systolic blood pressure, more rapid heart beat and quicker and more explosive responses to questions or association words. The behaviour of both animals and human beings, during anger, always shows a certain element of wildness, or lack of voluntary control. For this reason anger is psychologically defined (W. M. Marston) as an abnormal, conflict emotion, consisting of interrupted or thwarted dominance, aggressiveness or self-assertion.

See J. B. and R. R. Watson, "Studies in Infant Psychology," *Scientific Monthly* (1921); W. B. Cannon, *Bodily Changes in Pain, Hunger, Fear and Rage* (1920); W. M. Marston, "Sex Characteristics of Systolic Blood Pressure Behavior," *Journal Experimental Psychology* (1923); *The Emotions of Normal People* (1928).

(W. M. M.)

ANGERBURG, chief town of the south-western sub-division of the district of Gumbinnen, East Prussia. Pop. (1925) 6,911. It lies at the northern end of a long series of lakes, and serves as a road and rail centre. It makes small machinery and clay-products.

ANGERMÜNDE, a town of Germany in Brandenburg, on Lake Münde about 43m. from Berlin. Pop. (1925), 8,602. In 1420 the Elector Frederick I. of Brandenburg gained a victory here over the Pomeranians. The town is an important railway junction.

ANGERONA, a Roman goddess. According to ancient authorities, she relieved men from pain and sorrow, or delivered the Romans and their flocks from *angina* (quinsy); or she was the protecting goddess of Rome and the keeper of the sacred name of the city, which might not be pronounced lest it should be revealed to her enemies.

Modern scholars regard her as akin to Ops and Acca Larentia; or as the goddess of the new year and the returning sun. Her festival, called *Divalia* or *Angeronalia*, was celebrated Dec. 21. The priests offered sacrifice in the temple of Volupia, the goddess of pleasure, in which stood a statue of Angerona, with a finger on her mouth, which was bound and closed. She was worshipped as Ancharia at Faesulae (q.v.), where an altar belonging to her has been discovered.

ANGERS, capital of the department of Maine-et-Loire, west France, 191 m. S.W. of Paris by the Western railway to Nantes. Pop. (1926) 77,892. It occupies rising ground on both banks of the Maine, crossed by three bridges. The old town, on the left bank, is dominated by the cathedral and massive castle, and encircled by boulevards. On the right bank is the low-lying "Quartier de la Doutre." Angers is among the most handsome of French towns. Capital of the Gallic tribe of the Andegavi, it was known to the Romans as Juliomagus. During the 9th century it became the seat of the counts of Anjou (q.v.). It suffered severely from the invasions of the Northmen after 845 and of the English in the 12th and 15th centuries; the Huguenots took it in 1585, and the Vendean royalists were repulsed near it in 1793. Till the Revolution, Angers had a celebrated university (14th century). The cathedral of St. Maurice (12th and 13th centuries) has an unusually high west front, with three towers. The incongruous central tower (16th century) has a series of eight warriors carved on its base. The vaulting of the interior takes the form

of a series of cupolas. There are rich stained-glass windows (12th and 16th centuries) and valuable tapestries (14th and 18th centuries). The adjoining bishop's palace contains a fine synodal hall (12th century). Other churches are St. Serge, an abbey-church (12th and 15th centuries), and La Trinité (12th century). The prefecture occupies the famous abbey of St. Aubin; the courtyard has elaborately sculptured arcades and there is a tower

WEST FAÇADE OF SAINT-MAURICE CATHEDRAL AT ANGERS, FRANCE, A FINE EXAMPLE OF 13TH CENTURY GOTHIC ARCHITECTURE

surviving from the abbey church (both of the 11th and 12th centuries). Ruins of the old churches of Toussaint (13th century) and Notre-Dame du Ronceray (11th century) are also to be seen. The castle of Angers (13th century), girt with towers and a moat, is now used as an armoury. The hospital of St. Jean (12th century) is occupied by an archaeological museum; and the Logis Barrault, a Renaissance house, contains the public library, the municipal museum with pictures and sculptures, and the Musée David, containing works by the famous native sculptor David d'Angers. The Hôtel de Pincé or d'Anjou (1523-30) is a fine stone mansion. Many wooden houses of the 15th and 16th centuries remain. Angers is the seat of a bishopric, dating from the 3rd century, a prefecture, a court of appeal and a court of assizes. It has a tribunal of first instance, a tribunal of commerce, a board of trade-arbitrators, a chamber of commerce, and several learned societies. The ancient university was resuscitated in 1875 as the "Université Catholique de l'Ouest." There are several free faculties (*facultés libres*). The prosperity of the town is largely due to the great slate-quarries in the vicinity (whence its old name Black Angers); other products are liqueurs (from fruit), cables, ropes, thread, boots and shoes. The weaving of sail-cloth and woollen and other fabrics, machine construction, nursery-gardening and the making of umbrellas are carried on. The chief articles of commerce, besides slate and French and Swedish iron goods, are hemp, early vegetables, fruit, flowers, wine, oil, leather and live stock. Angers is the ancient capital of Anjou, and its people are still known as Angevins.

ANGERSTEIN, JOHN JULIUS (1735–1823), London merchant and patron of the fine arts, was born at St. Petersburg and settled in London about 1749. His collection of paintings, consisting of about 40 of the most exquisite specimens of the art, purchased by the British Government by a vote of £60,000, on his death, Jan. 22 1823, formed the nucleus of the National Gallery.

Angerstein was a great friend of Sir Thomas Lawrence, who helped him in the collection of his pictures and painted a portrait of him, which was given to the National Gallery by William IV.

See Young's *Catalogue of the celebrated Collection of Pictures of the late John Julius Angerstein* (1823); also *Nat. Gal. Catalogue*, Introduction to Foreign Schools.

ANGILBERT (d. 814), Frankish Latin poet, and minister of Charlemagne, was of noble Frankish parentage, and educated at the palace school under Alcuin. He is said to have been the father of two children by Charlemagne's daughter, Bertha, one of them named Nithard. From 790 he was abbot of St. Riquier, and in 800 he accompanied Charlemagne to Rome, and was one of the witnesses to his will in 814. Angilbert's poems show the culture and tastes of a man of the world, enjoying the closest intimacy with the imperial family; he was called the "Homer" of the emperor's literary circle, and a fragment of an epic, ascribed, probably correctly, to him, and called by its editors "Charlemagne et le pape Léon" describes the life at the palace and the meeting between Charlemagne and Leo III. Of the shorter poems, besides the greetings to Pippin on his return from the campaign against the Avars (796), an epistle to David (Charlemagne) incidentally reveals a delightful picture of the poet living with his children in a house surrounded by pleasant gardens near the emperor's palace. The reference to Bertha, however, is distant and respectful, her name occurring merely on the list of princesses to whom he sends his salutation.

Angilbert's poems have been published by E. Dümmler in the *Monumenta Germaniae Historica*. For criticism of this edition see Traube in Roederer's *Schriften für germanische Philologie* (1888).

ANGINA PECTORIS, a term applied to a violent paroxysm of pain, arising almost invariably from disease of the coronary arteries with consequent degeneration of the heart muscle (*see HEART, DISEASES OF*). An attack of angina pectoris usually consists in a sudden agonizing pain, felt at first over the heart, but radiating through the chest in various directions, and frequently extending down the left arm. A feeling of constriction and of suffocation accompanies the pain, although there is seldom actual difficulty in breathing. When the attack comes on, as it often does, during bodily exertion, the sufferer is at once brought to rest. The countenance becomes pale, the surface of the body cold, the pulse feeble, and death appears to be imminent, when suddenly the attack subsides and complete relief is obtained. The duration of a paroxysm rarely exceeds two or three minutes, but it may last longer. The attacks are apt to recur on slight exertion, and in aggravated cases without any such exciting cause. Occasionally the first seizure proves fatal. Angina pectoris is extremely rare under middle life, and is much more common in males than in females. In the treatment of the paroxysm, nitrite of amyl has now replaced all other remedies. It can be carried by the patient in the form of nitrite of amyl pearls, each pearl containing the dose prescribed by the physician. As soon as the pain begins the patient crushes a pearl in his handkerchief and holds it to his mouth and nose. The relief given in this way is marvellous and usually takes place within a very few seconds. To prevent recurrence of the attacks something may be done by administration of nitroglycerine, scrupulous attention to the general health and the avoidance of mental and physical strain.

Pseudo-Angina.—In this condition there occur praecordial pains which very closely resemble those of true angina. The essential difference lies in the fact that pseudo-angina is independent of structural disease of the heart and coronary arteries. There are three main varieties: (1) the reflex, (2) the vaso-motor, (3) the toxic. The reflex is by far the most common, and is generally due to irritation from one of the abdominal organs, often associated with mental anxiety or overwork. An attack of

pseudo-angina may be agonizing, the pain radiating through the chest and into the left arm, but the patient does not usually assume the motionless attitude of true angina, and the duration of the seizure is usually much longer. The treatment is that of the underlying neurosis and the prognosis is a good one, sudden death not occurring.

ANGIOSPERMS. The botanical term angiosperm (ἀγγεῖον, receptacle, and σπέρμα, seed) was coined in the form Angiospermae by Paul Hermann in 1690, as the name of that one of his primary divisions of the plant kingdom which included flowering plants possessing seeds enclosed in capsules, in contradistinction to his Gymnospermae, or flowering plants with fruits containing only one seed or dividing into distinct one-seeded portions—the whole fruit or each of its pieces being here regarded as a naked seed. These terms were maintained by Linnaeus with the same sense, but with restricted application, in the names of the orders of his class Didynamia. Their use with any approach to their modern scope only became possible after Robert Brown had established in 1827 the existence of truly naked seeds in the cycads and conifers, entitling them to be correctly called gymnosperms. From that time onwards, so long as these gymnosperms were, as was usual, reckoned as dicotyledonous flowering plants, the term angiosperm was used antithetically by botanical writers, but with varying limitation, as a group-name for other dicotyledonous plants. Wilhelm Hofmeister's brilliant discovery in 1851 of the changes occurring in the embryo-sac of flowering plants, and his determination of the correct relationships of these with the cryptogams (non-flowering plants), fixed the true position of gymnosperms as a class distinct from Dicotyledons, and the term angiosperm then gradually came to be accepted as the suitable designation for the whole of the flowering plants other than gymnosperms, and as including, therefore, the classes of Dicotyledons and Monocotyledons. This is the sense in which the term is used in this article.

The trend of the evolution of the plant kingdom has been in the direction of the establishment of a vegetation of fixed habit and adapted to the vicissitudes of a life on land, and the angiosperms are the highest expression of this evolution and constitute the dominant vegetation of the earth's surface at the present epoch. There is no land-area, from the poles to the equator, where plant-life is possible, upon which angiosperms are not found. They occur also abundantly in the shallows of rivers and fresh-water lakes, and in less numbers in salt lakes and in the sea; such aquatic angiosperms are not, however, primitive forms, but are derived from immediate land-ancestors. Associated with this diversity of habitat is great variety in general form and manner of growth. The familiar duckweed which covers the surface of a pond consists of a tiny green thalloid shoot, one, that is, which shows no distinction of parts—stem and leaf, and a simple root growing vertically downwards into the water. The great forest-tree has a shoot, which in the course perhaps of hundreds of years, has developed a wide-spreading system of trunk and branches, bearing on the ultimate twigs or branchlets innumerable leaves, while beneath the soil a widely-branching root-system covers an area of corresponding extent. Between these two extremes is every conceivable gradation, embracing aquatic and terrestrial herbs, creeping, erect, or climbing in habit, shrubs and trees, and representing a much greater variety than is to be found in the other subdivision of seed-plants, the gymnosperms.

Internal Structure.—In internal structure also the variety of tissue-formation far exceeds that found in gymnosperms (*see PLANTS: Anatomy*). The vascular bundles of the stem belong to the collateral type, that is to say, the elements of the wood or xylem and the bast or phloem stand side by side on the same radius. In the larger of the two great groups into which the angiosperms are divided, the Dicotyledons, the bundles in the very young stems are arranged in an open ring, separating a central pith from an outer cortex. In each bundle, separating the xylem and phloem, is a layer of meristem or active formative tissue, known as cambium; by the formation of a layer of cambium between the bundles (interfascicular cambium) a complete ring is formed, and a regular periodical increase in thickness results

from it by the development of xylem on the inside and phloem on the outside. The soft phloem soon becomes crushed, but the hard wood persists and forms the great bulk of the stem and branches of the woody perennial. Owing to differences in the character of the elements produced at the beginning and end of the season, the wood is marked out in transverse section into concentric rings, one for each season of growth—the so-called annual rings. In the smaller group, the Monocotyledons, the bundles are more numerous in the young stem and scattered through the ground tissue. Moreover, they contain no cambium and the stem once formed increases in diameter only in exceptional cases.

Vegetative Organs.—As in the gymnosperms, branching is monopodial, that is, a branch is always developed below the apex of the growing point of the stem or root, dichotomy, or the forking of the growing point into two equivalent branches which replace the main stem, is absent both in the case of the stem and the root. The leaves show a remarkable variety in form (*see LEAF*), but are generally small in comparison with the size of the plant; exceptions occur in some Monocotyledons, *e.g.*, in the Aroid family, where, in some genera the plant produces one huge, much-branched leaf each season, or in palms, where the unbranched stem bears a crown of large leaves.

In rare cases the main axis is unbranched and ends in a flower, as, for instance, in the tulip, where scale-leaves, forming the underground bulb, green foliage-leaves and coloured floral leaves are borne on one and the same axis. Generally, flowers are formed only on shoots of a higher order, often only on the ultimate branches of a much branched system. A potential branch or bud, either foliage or flower, is formed in the axil of each leaf; sometimes more than one bud arises, as for instance in the walnut, where two or three stand in vertical series above each leaf. Many of the buds remain dormant, or are called to development under exceptional circumstances, such as the destruction of existing branches. For instance, the clipping of a hedge or the lopping of a tree will cause to develop numerous buds which may have been dormant for years. Leaf-buds occasionally arise from the roots, when they are called adventitious; this occurs in many fruit trees, poplars, elms and others. For instance, the young shoots seen springing from the ground around an elm are not seedlings but root-shoots. Frequently, as in many Dicotyledons, the primary root, the original root of the seedling, persists throughout the life of the plant, forming, as often in biennials, a thickened tap-root, as in carrot, or in perennials, a much-branched root-system. In many Dicotyledons and most Monocotyledons, the primary root soon perishes and its place is taken by adventitious roots developed from the stem.

Flower.—The most characteristic feature of the angiosperm is the flower, which shows remarkable variety in form and elaboration and supplies the most trustworthy characters for the distinction of the orders and families into which the group is divided. The flower is a shoot (a stem bearing leaves) with a special form associated with the special function of ensuring the fertilization of the egg and the development of fruit containing seed. Except where it is terminal it arises, like the leaf-shoot, in the axil of a leaf, which is then known as a bract. Occasionally, as in the violet, a flower arises singly in the axil of an ordinary foliage-leaf; it is then termed axillary. Generally, however, the flower-bearing portion of the plant is sharply distinguished from the foliage-leaf-bearing or vegetative portion and forms a more or less elaborate branch-system in which the bracts are small and scale-like. Such a branch-system is called an inflorescence. The primary function of the flower is to bear the spores (minute one-celled reproductive organs). These, as in gymnosperms, are of two kinds, microspores or pollen-grains, borne in the stamens (or microsporophylls) and megaspores, in which the egg-cell is developed, contained in the ovule, which is borne enclosed in the carpel (or megasporophyll). The flower may consist only of spore-bearing leaves, as in the willow, where each flower comprises only a few stamens or two carpels. Usually, however, other leaves are present which are only indirectly concerned with the reproductive process, acting as protective organs for the sporophylls or forming an attractive envelope. These form the perianth and are in

one series, when the flower is termed monochlamydeous, or in two series (dichlamydeous). In the second case the outer series (calyx of sepals) is generally green and leaf-like, its function being to protect the rest of the flower, especially in the bud; while the inner series (corolla of petals) is generally white or brightly coloured, and more delicate in structure, its function being to attract the particular insect or bird by agency of which transference of pollen (pollination) is effected. The insect, or bird, is attracted by the colour and scent of the flower, and frequently also by nectar which is secreted in some part of the flower. (For further details on the form and arrangement of the flower and its parts, *see FLOWER*.)

Stamen and Pollen.—Each stamen generally bears four pollen-sacs (microsporangia) which are associated to form the anther and carried up on a stalk or filament. The development of the microsporangia and the contained spores (pollen-grains) is closely comparable with that of the microsporangia in gymnosperms or heterosporous ferns. The pollen is set free by the opening (dehiscence) of the anther, generally by means of longitudinal slits, but sometimes by pores, as in the heath family (*Ericaceae*), or by valves, as in the barberry. It is then dropped or carried by some external agent, wind, water, or some member of the animal kingdom, on to the receptive surface of the carpel of the same or another flower. The carpel, or aggregate of carpels forming the pistil or gynaecium, comprises an ovary containing one or more ovules and a receptive surface or stigma; the stigma is sometimes carried up on a style. The mature pollen-grain is, like other spores, a single cell; except in the case of some submerged aquatic plants, it has a double wall, a thin delicate wall of unaltered cellulose, the endospore or intine, and a tough outer cuticularized exospore or extine. The exospore often bears spines or warts, or is variously sculptured, and the character of the markings is often of value for the distinction of genera or higher groups. Germination of the microspore begins before it leaves the pollen-sac. In very few cases has anything representing the development of tissue, comparable with the prothallium of a fern, been observed; generally a small cell (the antheridial or generative cell) is cut off, leaving a larger tube-cell. When placed on the stigma, under favourable circumstances, the pollen-grain puts forth a pollen-tube which grows down the tissue of the style to the ovary, and makes its way along the placenta, guided by projections or hairs, to the mouth of an ovule. The nucleus of the tube-cell has meanwhile passed into the tube, as does also the generative nucleus which divides to form two male or sperm-cells. The male cells are carried to their destination in the tip of the pollen-tube.

Pistil and Embryo-Sac.—The ovary contains one or more ovules borne on a placenta, which is generally some part of the ovary-wall. The development of the ovule, which represents the macrosporangium, is very similar to the process in gymnosperms; when mature it consists of one or two coats surrounding the central nucellus; except at the apex where an opening, the micropyle, is left. The nucellus is a cellular tissue enveloping one large cell, the embryo-sac or macrospore. The germination of the macrospore consists in the repeated division of its nucleus to form two groups of four, one group at each end of the embryo-sac. One nucleus from each group, the polar nucleus, passes to the centre of the sac, where the two fuse to form the endosperm nucleus. Of the three cells at the micropylar end of the sac, all naked cells (the so-called egg-apparatus), one is the egg-cell or oosphere, the other two, which may be regarded as representing abortive egg-cells (in rare cases capable of fertilization), are known as synergidae. The three cells at the opposite end are known as antipodal cells and become invested with a cell-wall. The gametophyte or prothallial generation is thus extremely reduced, consisting of but little more than the male and female sexual cells—the two sperm-cells in the pollen-tube and the egg-cell (with the synergidae) in the embryo-sac.

Fertilization.—At the period of fertilization the embryo-sac lies in close proximity to the opening of the micropyle, into which the pollen-tube has penetrated, the separating cell-wall becomes absorbed, and the male or sperm-cells are ejected into the embryo-sac. Guided by the synergidae one male-cell passes into the oosphere with which it fuses, the two nuclei uniting, while the other

fuses with the endosperm-nucleus. After impregnation the fertilized oosphere immediately surrounds itself with a cell-wall and becomes the oospore, which by a process of growth forms the embryo of the new plant. The endosperm-nucleus divides rapidly to produce a cellular tissue which fills up the interior of the rapidly growing embryo-sac, and forms a tissue, endosperm, in which is stored a supply of nourishment for the use later on of the embryo.

We can recognize, therefore, two products of fertilization—one, the embryo, which becomes the future plant; the other, the endosperm, a short-lived undifferentiated nurse to assist in the nutrition of the former. The endosperm, like the embryo, being the product of a sexual act, hybridization will give a hybrid endosperm as it does a hybrid embryo, and herein we may have the explanation of the phenomenon of "xenia" observed in the mixed endosperms of hybrid races of maize and other plants. The antipodal cells aid more or less in the process of nutrition of the developing embryo, and may undergo multiplication, though they ultimately disintegrate, as do also the synergidae. As in gymnosperms and other groups an interesting qualitative change is associated with the process of fertilization. The number of chromosomes (*see* CYTOLOGY) in the nucleus of the two spores, pollen-grain and embryo-sac is only half the number found in an ordinary vegetative nucleus, and this reduced number persists in the cells derived from them. The full number is restored in the fusion of the male and female nuclei in the process of fertilization and remains until the formation of the cells from which the spores are derived in the new generation.

The above is a general account representing the normal sequence of events, but various departures have been noted. Thus in the family Rosaceae, the order Fagales and the anomalous genus *Casuarina* and others, instead of a single macrospore a sporogenous tissue is formed, but only one cell proceeds to the formation of a functional female cell. In *Casuarina*, *Juglans* and the family Corylaceae, the pollen-tube does not enter by means of the micropyle, but, passing down the ovary-wall and through the placenta, enters at the opposite, or chalazal, end of the ovule. Such a method of entrance is styled chalazogamic, in contrast to the porogamic or ordinary method of approach by means of the micropyle.

Embryology.—The result of fertilization is the development of the ovule into the seed. By the segmentation of the fertilized egg, invested by cell-membrane, the embryo plant arises. A varying number of transverse segment-walls transform it into a pro-embryo—a cellular row of which the cell nearest the micropyle becomes attached to the apex of the embryo-sac, and thus fixes the position of the developing embryo, while the terminal cell is projected into its cavity. In Dicotyledons the shoot of the embryo is wholly derived from the terminal cell of the pro-embryo, from the next cell the root arises, and the remaining ones form the suspensor. In many Monocotyledons the terminal cell forms the cotyledonary portion alone of the shoot of the embryo, its axial part and the root being derived from the adjacent cell; the cotyledon is thus a terminal structure and the apex of the primary stem a lateral one—a condition in marked contrast with that of the Dicotyledons. In some Monocotyledons, however, the cotyledon is not really terminal. The primary root of the embryo in all angiosperms points towards the micropyle. The developing embryo at the end of the suspensor grows out to a varying extent into the forming endosperm, from which by surface absorption it derives food-material for growth; at the same time the suspensor plays a direct part as a carrier of nutrition, and may even develop, where perhaps no endosperm is formed, special absorptive "suspensor roots" which invest the developing embryo, or pass out into the body and coats of the ovule, or even into the placenta. In some cases the embryo or the embryo-sac sends out suckers into the nucellus and ovular integument. As the embryo develops it may absorb all the food-material available, and store, either in its cotyledons or in its hypocotyl (the short portion of the stem below the cotyledons), what is not immediately required for growth, as reserve-food for use in germination, and by so doing it increases in size until it may fill entirely the embryo-sac; or its absorptive power at this stage may be limited to what is necessary for growth

and it remains of relatively small size, occupying but a small area of the embryo-sac, which is otherwise filled with endosperm in which the reserve-food is stored. There are also intermediate states. The position of the embryo in relation to the endosperm varies; sometimes it is internal, sometimes external, but the significance of this has not yet been established.

The formation of endosperm starts, as has been stated, from the endosperm-nucleus. Its segmentation always begins before that of the egg, and thus there is timely preparation for the nursing of the young embryo. If in its extension to contain the new formations within it the embryo-sac remains narrow, endosperm formation proceeds upon the lines of a cell-division; but in wide embryo-sac the endosperm is first of all formed as a layer of naked cells around the wall of the sac and only gradually acquires a pluricellular character, forming a tissue filling the sac. The function of the endosperm is primarily that of nourishing the embryo, and its basal position in the embryo-sac places it favourably for the absorption of food material entering the ovule. Its duration varies with the precocity of the embryo. It may be wholly absorbed by the progressive growth of the embryo within the embryo-sac, or it may persist as a definite and more or less conspicuous constituent of the seed. When it persists as a massive element of the seed its nutritive function is usually apparent, for there is accumulated within its cells reserve-food, and according to the dominant substance it is starchy, oily, or rich in cellulose, mucilage, or proteid. In cases where the embryo has stored reserve-food within itself and thus provided for self-nutrition, such endosperm as remains in the seed may take on other functions, for instance, that of water-absorption.

Some deviations from the usual course of development may be noted. Parthenogenesis, or the development of an embryo from an egg-cell without the latter having been fertilized, has been described in species of *Thalictrum*, *Antennaria*, and *Alchemilla*. Polyembryony is generally associated with the development of cells other than the egg-cell. Thus in *Erythronium* and *Linnocharis* the fertilized egg may form a mass of tissue on which several embryos are produced. Isolated cases show that any of the cells within the embryo-sac may exceptionally form an embryo, *e.g.*, the synergidae in species of *Mimosa*, *Iris*, and *Allium*, and in the last-mentioned the antipodal cells also. In *Coelebogryne* (Euphorbiaceae) and in *Funkia* (Liliaceae) polyembryony results from an adventitious production of embryos from the cells of the nucellus around the top of the embryo-sac. In a species of *Allium* embryos have been found developing in the same individual from the egg-cell, synergids, antipodal cells, and cells of the nucellus. In two Malayan species of *Balanophora* the embryo is developed from a cell of the endosperm, which is formed from the upper polar nucleus only, the egg-apparatus becoming disorganized. The last-mentioned case has been regarded as representing an apogamous development of the sporophyte from the gametophyte comparable to the cases of apogamy described in ferns. But the great diversity of these abnormal cases as shown in the examples cited above suggests the use of much caution in formulating definite morphological theories upon them.

As the development of embryo and endosperm proceeds within the embryo-sac its wall enlarges and commonly absorbs the substance of the nucellus (which is likewise enlarging) to near its outer limit, and combines with it and the integument to form the seed-coat; or the whole nucellus and even the integument may be absorbed. In some plants the nucellus is not thus absorbed, but itself becomes a seat of deposit of reserve-food constituting the perisperm which may coexist with endosperm, as in the water-lily family (Nymphaeaceae), or may alone form a food-reserve for the embryo, as in *Canna*. Endospermic food-reserve has evident advantages over perispermic, and the latter is comparatively rarely found. Seeds in which endosperm or perisperm, or both, exist are commonly called albuminous or endospermic; those in which neither is found are termed exalbuminous or ex-endospermic. The presence or absence of endosperm, its relative amount when present, and the position of the embryo within it are valuable characters for the distinction of families and orders, or groups of families. Meanwhile the ovary-wall has developed to

form the fruit or pericarp, the structure of which is closely associated with the manner of distribution of the seed. Frequently the influence of fertilization is felt beyond the ovary, and other parts of the flower take part in the formation of the fruit, as the floral receptacle in the apple, strawberry, and others. The character of the seed-coat bears a definite relation to that of the fruit. Its function is the twofold one of protecting the embryo and of aiding in dissemination; it may also directly promote germination. If the fruit is a dehiscent one and the seed is, therefore, soon exposed, the seed-coat has to provide for the protection of the embryo and may also have to secure dissemination. On the other hand, indehiscent fruits discharge these functions for the embryo, and the seed-coat is only slightly developed.

Dissemination.—Dissemination is effected by an explosive mechanism resident in the fruit or seed, or by aid of some external agency—water, air, or animals. The need for this is obvious—buoyancy in water and resistance to wetting for the first, some sort of parachute for the second, and some attaching mechanism or attractive structure for the third. The methods in which these are provided are of infinite variety, and any and every part of the flower and of the inflorescence may be called into requisition to supply the adaptation (*see* FRUIT). Special outgrowths, arils, of the seed-coat are of frequent occurrence. In the feature of the fruit and seed, by which the distribution of angiosperms is effected, we have a distinctive character of class. In gymnosperms we have seeds, and the carpels may become modified and close around these, as in *Pinus* during the process of ripening to form an imitation of a box-like fruit which, subsequently opening, allows the seeds to escape; but there is never in them the closed ovary investing from the outset the ovules and ultimately forming the groundwork of the fruit.

Germination of Seed.—Their fortuitous dissemination does not always bring seeds upon a suitable nidus for germination, the first need for which is a sufficiency of moisture, and the duration of vitality of the embryo is a point of interest. Some seeds retain vitality for a period of many years, though there is no warrant for the popular notion that genuine "mummy wheat" will germinate; on the other hand some seeds lose vitality in a very short time. Further, the older the seed the more slow as a general rule will germination be in starting; but there are notable exceptions. This pause, often of so long duration, in the growth of the embryo between the time of its perfect development within the seed and the moment of germination, is one of the remarkable and distinctive features of the life of seed-plants (spermatophytes). The aim of germination is the fixing of the embryo in the soil, effected usually by means of the root, which is the first part of the embryo to appear, in preparation for the elongation of the portion of the shoot above the cotyledons (*epicotyl*), and there is infinite variety in the details of the process. In endospermic Dicotyledons the cotyledons act as the absorbents of the reserve-food of the seed and are commonly brought above ground (*epigeal*), either withdrawn from the seed-coat or carrying it upon them, and then they serve as the first green organs of the plant. The part of the stem below the cotyledons (*hypocotyl*) commonly plays the greater part in bringing this about. Exendospermic Dicotyledons usually store reserve-food in their cotyledons, which may in germination remain below ground (*hypogeal*). In endospermic Monocotyledons the cotyledon itself, probably in consequence of its terminal position, is commonly the agent by which the embryo is thrust out of the seed, and it may function solely as a feeder, its extremity developing as a sucker through which the endosperm is absorbed, or it may become the first green organ, the terminal sucker dropping off with the seed-coat when the endosperm is exhausted. Exendospermic Monocotyledons are either hydrophytes or strongly hygrophilous plants and have often peculiar features in germination.

Vegetative Reproduction.—Distribution by seed appears to satisfy so well the requirements of angiosperms that distribution by vegetative buds is only an occasional process. At the same time every bud on a shoot has the capacity to form a new plant if placed in suitable conditions, as the horticultural practice of propagation by cuttings shows; in nature we see plants spreading

by the rooting of their shoots, and buds we know may be freely formed not only on stems but on leaves and on roots. Where detachable buds are produced, which can be transported through the air to a distance, each of them is an incipient shoot which may have a root, and there is always reserve-food stored in some part of it. In essentials such a bud resembles a seed. A relation between such vegetative distribution buds and production of flower is usually marked. Where there is free formation of buds there is little flower and commonly no seed, and the converse is also the case. Viviparous plants are an illustration of substitution of vegetative buds for flower. In these cases the ovule is replaced by a minute plantlet which develops *in situ* and separates from the plant when it is able to maintain an independent existence. This occurs in some grasses and other species living in Arctic or other situations where the normal course of seed-development as the result of fertilization is uncertain.

Phylogeny and Taxonomy.—Reference is made in the general article BOTANY to early systems of classification and to the evolution of the idea of a natural system in which families were grouped according to their affinities. This found expression in British botany in the system elaborated by George Bentham and Joseph Hooker in the *Genera Plantarum* (1862-1883), in which all known genera of flowering plants were described and arranged in families and higher groups. The system was based on that of the De Candolles and has been widely used in Great Britain and America. It will illustrate the principles of a system which, without claiming to be phylogenetic, represents in the sequence adopted a progression from simpler to more advanced families. The families of the two great divisions, Dicotyledons and Monocotyledons, are grouped in cohorts (or series); those of the Dicotyledons are arranged in three subdivisions: Polypetalae, where the petals are free from each other, Gamopetalae, with a corolla of united petals, and Monchlamydeae, without a corolla, and where the flower often consists merely of the reproductive organs. (*See* the article FLOWER for illustrations.) In the first two subdivisions the cohorts are arranged in a progressive series according to the relative position of the gynaeceum and the other floral whorls; in the simplest forms sepals, petals, and stamens stand below the carpels on the floral axis (*i.e.*, are hypogynous), while in the most advanced they spring from the top of the ovary (*i.e.*, are epigynous). Diminution of the number of parts in the flower is also an indication of an advance, especially the number of carpels which in the most advanced members of each subdivision is reduced to two. A spiral arrangement of the floral leaves is also more primitive than a whorl; and a regular flower, that is one showing a radial structure, than one which is symmetrical only about one plane. To some extent also a woody habit indicates less advance than an herbaceous.

A great drawback to the value of this system is the inclusion among the Monochlamydeae of a number of families which are closely allied with families of Polypetalae though differing in absence of a corolla. The German systematist, A. W. Eichler, attempted to remove this disadvantage which since the time of Jussieu had characterized the French system, and in 1883 grouped the Dicotyledons in two subclasses. The earlier subclass, Chori-petalae, embraces the Polypetalae and Monochlamydeae of the French and English systems, and is an attempt to arrange as far as possible in a linear series those families which are characterized by absence or freedom of petals. A modification of Eichler's system, embracing more recent views of the affinities of the families of angiosperms, has been put forward by Dr. Adolf Engler of Berlin, who adopts the suggestive names Archichlamydeae and Metachlamydeae for the two subdivisions of Dicotyledons. Engler regarded his system as phylogenetic; simplicity of floral structure was considered primitive and the earlier orders (as groups of families are now termed) in his system are thus characterized. But he recognized that a simple type of flower may also appear in an advanced group and is then obviously derived; and many botanists would regard all families characterized by simple flowers as derived from more advanced forms.

Divergent views as to the origin of the angiosperms have some bearing on this problem. The angiosperms appear in the Creta-

ceous period as a well-developed and widely distributed group of plants with the characters of the existing class. The fossil remains may be distributed among existing families and genera and give no clue to the early history of the group.

The great antiquity of the other class of seed-plants, the gymnosperms, has suggested that the origin of the angiosperms should be sought within it. Thus Richard Wettstein seeks to derive a simple form of flower from an ancestor, resembling *Ephedra* (Gnetaceae), and regards the simple flower as primitive in the angiosperms. A view which has found considerable support regards the extinct Mesozoic Cycadeoidea, a group allied to the cycads, as the nearest approach known to the ancestral angiosperm stock. The "flower" of Bennettites (see PALAEOBOTANY), which has an elongated axis bearing sterile leaves below and micro- and macro-sporophylls above, is regarded as the forerunner of the angiosperm flower as exhibited, for instance, in *Magnolia*, a perfect bisexual flower with free sepals, petals, stamens, and carpels following in spiral succession on an elongated floral receptacle. On this theory, which has been developed by E. A. N. Arber and J. W. Parkin (see *Journ. Linn. Soc. [Bot.]* xxxviii. 29, 1907), this type of flower represents the starting point of a phylogenetic system of classification of Dicotyledons. Such are the systems elaborated by C. E. Bessey in America, Hans Hallier in Germany, and recently by John Hutchinson in England.

It is, however, probable that the original stock of the angiosperms has not yet been traced. A vast number of forms must have arisen and become extinct in the course of evolution of the group, and among these may be some of which certain of the existing simple-flowered groups are surviving representatives.

The relation of the two divisions, Dicotyledons and Monocotyledons, has also been much debated. Had each group a separate origin or has one been derived from the other? Botanists who uphold the Bennettites ancestry of Dicotyledons would derive the Monocotyledons from the base of the dicotyledonous stock. On the other hand strong arguments have been adduced in favour of its distinct origin, the two divisions representing a parallel development.

A phylogenetic tree including the whole plant-kingdom has recently been elaborated by Carl Mez and H. Ziegenspeck, based on the reaction to serum of members of the various families (see Von C. Mez and H. Ziegenspeck, "Der Königsberger Serodiagnostische Stammbaum," *Mez, Botanisches Archiv*. xiii. 482 [1926]).

ANGKOR, an assemblage of ruins in Cambodia, the relic of the ancient Khmer civilization. They are situated in forests to the north of the Great Lake (Tonle-Sap), the most conspicuous of the remains being the town of Angkor-Thom and the temple of Angkor-Vat, both of which lie on the right bank of the river Siem-Reap, a tributary of the Tonle-Sap. Other remains of the same character lie scattered about the vicinity on both banks of the river. It has been decided to enclose them in a park.

Angkor-Thom, according to Aymonier, was begun about A.D. 860 and finished towards A.D. 900. Within a rectangular enclosure, nearly 2m. in each direction, which is entered by five monumental gates, are the remains of palaces and temples, overgrown by the forest. The chief of these are: (1) The vestiges of the royal palace and the pyramidal religious structure known as the Phimeanakas, both of which stood within an enclosure to the east of which extends a terrace decorated with magnificent reliefs. (2)

The temple of Bayon, consisting of a double system of galleries enclosing a cruciform structure, at the centre of which rises a huge tower with a circular base. Fifty towers, decorated with quadruple faces of Brahma, are built at intervals upon the galleries, the whole temple ranking as perhaps the most remarkable of the Khmer remains.

Angkor-Vat, the best preserved example of Khmer architecture, lies less than a mile to the south of the royal city, within a park surrounded by a moat, the outer perimeter of which measures 6,060 yards. Although sometimes said to have been devoted to the worship of Brahma, the French school of the Far East now thinks that the temple was consecrated to the worship of Buddha. It consists of three stages, connected by exterior staircases and decreasing in dimensions as they rise, culminating in the sanctuary, a great central tower pyramidal in form. Three galleries with vaulting supported on columns lead from the three western portals to the second stage. They are connected by a transverse gallery thus forming four square basins. Khmer decoration, profuse but harmonious, consists chiefly in the representation of gods, men and animals, which are displayed on every flat surface. Combats and legendary episodes are often depicted; floral decoration is reserved chiefly for borders, mouldings and capitals. Sandstone of various colours was the chief material employed by the Khmers, without the use of cement; limonite was also used. (See CAMBODIA.)

ANGLE, in plane geometry, a figure formed by two lines which meet. The point of meeting is called the *vertex* of the angle. The original idea has been extended to include the figure formed by a plane and a line which meets it, by two intersecting planes (a *dihedral angle*), by three planes having a common point (a

FIG. 1.—ACUTE, OBTUSE AND REFLEX ANGLES

trihedral angle), by any number of planes having a common point (a *polyhedral angle*), or by two intersecting curves (a *curvilinear angle*). The angle in the last case is measured by the angle formed by tangents to the curves at their common point; it may also be formed by a curve and a straight line (*mixed angle*). The concept has also been extended to include the case of two lines in space

FIG. 2.—TWO COMPLEMENTARY AND TWO SUPPLEMENTARY ANGLES

that are not parallel and yet do not meet, like the upper edge of a box and a lower non-parallel one (*skew angle*). There are also *spherical angles*, formed by the intersection of two great circles of a sphere. An angle is measured by the amount of turning necessary to bring one of the lines (arms, sides, legs) into coincidence with the other, this being measured on a circle with its vertex (from Lat. *vertere*, to turn) at the centre.

The early idea of angle limited the concept to an angle less than 180°. The demands of science lead modern writers to speak of a *straight angle* (180°), a *reflex angle*, and of angles exceeding 360°, as in speaking of an angle arising from turning a radius

beyond a complete revolution. This is seen in any rotary motion. An angle less than a right angle (90°) is said to be *acute*; between 90° and 180° , *obtuse*; and between 180° and 360° , *reflex*. The angle $90^\circ - a$ is the *complement* of angle a ; for example, the complement of 40° is $90^\circ - 40^\circ$, or 50° . The angle $180^\circ - b$ is the *supplement* of angle b .

The term angle is itself such a basal term that it is not possible to give a satisfactory definition employing terms more simple than

FIG. 3.—DIHEDRAL, ADJACENT AND SYMMETRIC POLYHEDRAL ANGLES

itself. Hilbert's definition represents one of the late efforts: "Let a be any arbitrary plane and h , k any two distinct half-rays lying in a and emanating from the point o so as to form a part of two different straight lines. We shall call the system formed by these two half-rays h , k an angle."

ANGLER (*Lophius piscatorius*), also called the fishing frog, belongs to the order *Pediculati*. It is a bottom-living fish, abundant round the coasts of Europe and western North America; it does not extend beyond 60° N. lat. The enormous mouth, with long, backwardly-directed, depressible teeth, and the large flattened head are diagnostic points. The fish walks along the bottom by means of its paired fins, which are modified for this purpose. The first three rays of the anterior dorsal fin are long filaments placed on the head; the first, the longest, ends in a lappet, is freely movable, and acts as a lure to attract other fish. So large is the mouth and so extensible the stomach that the angler can engulf fish as big as or bigger than itself. It may reach a length of 5 ft. The spawn consists of a transparent, gelatinous sheet, 2 or 3 ft. broad and 25–30 ft. long. In this the eggs are embedded. A second species (*L. budegassa*) occurs in the Mediterranean and a third (*L. litulon*) on the coasts of Japan. Tropical species have 19 vertebrae instead of 26 to 32, and are placed in a distinct genus *Lophomus*.

The order *Pediculati* includes also a number of little fishes (*Antennarius*, etc.) found in shallow water in warm seas and also a group, the *Ceratioids*, that live in the darkness of the middle depths of the ocean, from about 500 to 1,500 metres below the surface. These are blackish fishes, with a luminous lure; the males are dwarfed and parasitic on the females. (See *FISHES*.)

ANGLESEY, ARTHUR ANNESLEY, 1ST EARL OF (1614–1686), British statesman, son of the 1st Viscount Valentia (cr. 1621), born at Dublin on July 10, 1614, was educated at Magdalen College, Oxford, and admitted to Lincoln's Inn in 1634. He was commissioned by the English parliament in a mission to the duke of Ormonde, with whom he concluded a treaty on June 19, 1647. In that year he entered the House of Commons as member for Radnorshire, and supported the Parliamentary as against the Republican or Army Party. The anarchy of the last months of the Commonwealth converted him to the Royalist side and he helped to bring about the restoration. In 1661 he was created Baron Annesley and earl of Anglesey in the British peerage. From 1660 to 1667 he held various offices in the Irish administration, and in the British House of Commons supported Irish interests.

In the bitter religious controversies of his time Anglesey showed moderation and toleration. In the panic over the "Popish Plot" in 1678 he kept his head. He was one of the four peers who protested in that year against the bill for the disarming of convicted recusants; he was the only peer to dissent from the motion declaring the existence of an Irish plot; he interceded for Lord Stafford,

although he believed in his guilt; and in 1683 he appeared as a witness in defence of Lord Russell. He died at Bletchington in Oxfordshire on April 26, 1686.

The unfavourable character drawn of him by Burnet is certainly unjust and not supported by any evidence. Pepys, a far more trustworthy judge, speaks of him invariably in terms of respect and approval as a "grave, serious man," and commends his appointment as treasurer of the navy as that of "a very notable man, and understanding, and will do things regular and understand them himself." He was a learned and cultivated man and collected a celebrated library, which was dispersed at his death. His works include *A True account of the Whole Proceedings betwixt . . . the Duke of Ormond and . . . the Earl of Anglesey* (1682).

Memoirs of Lord Anglesey were published by Sir P. Pett in 1693, but contain little biographical information and were repudiated as a mere imposture by Sir John Thompson (Lord Haversham), his son-in-law, in his preface to Lord Anglesey's *State of the Government* in 1694. However, the author of the preface to *The Rights of the Lords asserted* (1702), while blaming their publication as "scattered and unfinished papers," admits their genuineness.

BIBLIOGRAPHY.—*Dict. of Nat. Biography*, with authorities there collected; lives in Wood's *Athenae Oxonienses* (Bliss), iv. 181, *Biographia Britannica*, and H. Walpole's *Royal and Noble Authors* (1806), iii. 288 (the latter a very inadequate review of Anglesey's character and career); also *Bibliotheca Anglesiana* . . . per Thomam Philippum (1686); *The Happy Future State of England*, by Sir Peter Pett (1688); *Great News from Poland* (1683), where his religious tolerance is ridiculed. *Somers Tracts* (Scott, 1812), viii. 344; *Notes of the Privy Council* (Roxburghe Club, 1896); *Cal. of State Papers, Dom.*; *State Trials*, viii. and ix. 619.

ANGLESEY, HENRY WILLIAM PAGET, 1ST MARQUIS OF (1768–1854), British field-marshal, was born May 17, 1768, the eldest son of Henry Paget, 1st Earl of Uxbridge, and was educated at Westminster School and Christ Church, Oxford. He served with distinction in the French revolutionary wars, and by 1808 had risen to be lieutenant-general. In command of the cavalry in Sir John Moore's Corunna campaign, he won the highest praise. His liaison with the wife of Henry Wellesley made it impossible at that time for him to serve with Wellington, and he did not serve actively, except during the disastrous Walcheren campaign, until in 1815 he commanded the British cavalry in Flanders. Wellington put him in command of the whole of the allied cavalry and horse artillery. He covered the retirement from Quatre Bras, and led the cavalry charge of the British centre which checked and in part routed d'Erlon's *corps d'armée* at Waterloo. He received a severe wound, which necessitated the amputation of his leg. He received a marquise and other honours for his services, which were regarded as second only to those of the duke himself.

Anglesey became lord lieutenant of Ireland (1828) under Wellington's Government, and his recall, after a brief tenure of the office, on account of his advocacy of the relief of the Catholics from the penal laws imposed on them, was much regretted in Ireland. But in 1830, after the cause was won, he again became lieutenant under Earl Grey's Government. He had to face O'Connell's agitation for the repeal of the Union, and asked for coercive powers. In July 1833 the ministry resigned. His best legacy to Ireland was the Board of Education, established during his viceroyalty. Anglesey remained in retirement until 1846, when he became master-general of the ordnance. In that year he was promoted to the rank of field-marshal. He died April 29, 1854.

The marquis had two sons and six daughters by his first wife, and six sons and four daughters by the second. His eldest son, Henry, succeeded him in the marquise; but the title passed rapidly in succession to the 3rd, 4th and 5th marquises. The last, whose extravagances were notorious, died in 1905, when the title passed to his cousin.

Other members of the Paget family distinguished themselves in the Army and the Navy. Of the first marquis's brothers, one, SIR CHARLES PAGET (1778–1839), rose to the rank of vice-admiral in the Royal Navy; another, General SIR EDWARD PAGET (1775–1849), won great distinction by his skilful handling of a division

at Corunna, and from 1822 to 1825 was commander-in-chief in India. One of the marquis's sons by his second marriage, LORD CLARENCE EDWARD PAGET (1811-95), became an admiral; another, LORD GEORGE AUGUSTUS FREDERICK PAGET (1818-80), led the 4th Light Dragoons in the charge of the Light Brigade at Balaklava; and subsequently commanded the brigade, and, for a short time, the cavalry division in the Crimea. In 1865 he was made inspector-general of cavalry, in 1871 lieutenant-general and K.C.B., and in 1877 full general. His Crimean journals were published in 1881.

ANGLESEY or **ANGLESEA**, an insular northern county of Wales, area about 276sq.m., is cut off from the adjoining mainland of Carnarvonshire by the shallow Menai strait. The island differs strikingly from most other parts of Wales in the lowness of the land—the highest points being 720ft., on Holy island in the north-west, and 494ft. on Parys mountain in the north-east. It is a much worn down ancient highland, the worn ribs of which run as lines of moorland between slightly lower lines of marsh in a north-easterly to south-westerly direction. Three distinct lines of very ancient rock (pre-Cambrian schists and slates), now worn down almost to sea level, follow the general north-easterly to south-westerly trend. The north-western section includes Holyhead and Llanfaethlu, the central Aberffraw and Trefdraeth, and the south-eastern Newborough and Pentraeth. In the region between the central and north-west lowland just described, we have slightly higher ground, composed of granite on its southern side, and much folded Ordovician slates and grits on the north. The latter fan out to the north-east of the island, where volcanic intrusions have given rich veins of copper at Parys mountain. Between the central and southern pre-Cambrian peninsulas the slightly raised ground is mostly composed of carboniferous limestone. Similar patches of limestone outcrop on the extreme south of the island, forming the northern shore of the Menai strait. The latter is just another of these lower north-easterly to south-westerly lines that has been submerged, and is more picturesque, if less wild, than the island marshes lying parallel to it. There are abundant evidences of glaciation, and much boulder clay and drift sand cover the older rocks. Patches of blown sand occur on the south-west coast.

The importance of Anglesey in prehistoric times is clearly indicated by the large number of megalithic monuments (chiefly dolmens, called in Wales cromlechs, and menhirs), that cover the island, especially in the south and west (see E. N. Baynes, "The Megalithic Remains of Anglesey," *Cymmrod. Soc. Trans.* 1910-11, pp. 3-91). Thus Anglesey, together with many of the western promontories of Britain, France and Spain, seems to have been an important station on the coastwise and transpeninsular routes between Spain and Ireland (see PEMBROKESHIRE). A group of mediaeval chapels in the neighbourhood of Holyhead suggests the continual use of this route along lines similar to that at St. David's (q.v.) in mediaeval times. There are indications that a similar maritime trade reached Anglesey in the late bronze age. Finds of exotic bronzes, a gold bracelet and jet beads have occurred in the centre of the island and near the coast at Holyhead and Beaumaris. Occupational evidences of some shortly pre-Roman period are to be found in the Hut circles at Ty Mawr on Holyhead mountain. Agricola is known to have conquered and settled Anglesey about A.D. 78. The island was known to the Romans as Mona, and recorded by them as the home of the Druids. Domestic implements of native workmanship are found at Pen-y-Bone in connection with Roman coins of the 1st and 2nd centuries, as well as Samian ware and cinerary urns of Roman origin. In the turbulent post-Roman centuries Anglesey seems to have been the prey of raiders from Ireland, Man, Scotland, England, and Wales. The Scandinavian raids, and the conquest of the island by the Saxons, under Egbert, and their ultimate expulsion seem to be the outstanding features. The raids did not cease with the arrival of the Normans, as the fatal expedition of Hugh of Chester in 1098 shows. They realized that although they could retain the lowlands of South Wales and the Border, Anglesey and Powys could not be retained without serious risk of disaster. Consequently the island retained a measure of independence throughout the early

middle ages, and at Aberffraw was located a capital of the Welsh princes of Gwynedd. The large expanses of low-lying ground (so rare in Wales) and the small rainfall, made the island one of the chief corn producing regions of the principality, and thereby earned it its name of "Môn Mam Cymru" ("Anglesey the mother [nourisher] of Wales"). The county was finally subdued by Edward I., who built an important castle at Beaumaris in 1295-96 and declared Aberffraw the capital of the island. Old traditions and customs, enriched by the age-long contacts with Ireland, lingered long in Anglesey, and gave a peculiar interest and charm to the mediaeval descriptions of the court at Aberffraw. Penmon priory, 4½m. from Beaumaris, was the most important monastic house, founded on an earlier site in the early part of the 13th century.

For centuries after the Edwardian conquest, the remoteness of Anglesey from the English plain made it the centre for those who plotted against the Crown. It became important for its sea-faring and fisheries. Its people were deeply attached to the royalist cause in the 17th century. The development of Holyhead as a packet station for Ireland is the central feature in modern Anglesey, and provides an interesting example of how a route famous from prehistoric days has lived on under modern conditions. It was a regular station in the reign of William III., and was selected by the Government in 1801 as an Irish Packet station, and as the terminus of Telford's great road (1815-19) from Shrewsbury, which crossed the island from south-east to north-west. A fine harbour was built by the London and North Western railway in 1880, and since then most of the Irish traffic to England has passed through Anglesey. Copper mining at Parys mountain in the north-east of the county was important between 1762-1850. Other minerals, including coal, have been worked in small quantities at different times in the island. Agriculture, sheep rearing and coastal fishing provide occupation for the bulk of the population at the present time. The county is connected with the mainland by two bridges over the Menai strait, viz., Telford's suspension bridge (1819-26) the largest in the kingdom, built at the zenith of the stage coach traffic, and Stephenson's tubular railway bridge, built in 1850.

The L.M.S. railway (Chester and Holyhead branch) crosses Anglesey from Llanfairpwllgwyngyll to Caerwen and Holyhead (Gaergybi), also from Gaerwen to Amlwch. The population of the county in 1931 was 49,025. There is no parliamentary borough, but one member is returned for the county. It is in the north-west circuit, and assizes are held at Beaumaris, the only municipal borough, pop. (1931) 1,708. Amlwch (2,561), Holyhead (10,707), Llangefni (1,782), and Menai Bridge (Pont y Borth) (1,675) are urban districts. The island is in the see of Bangor, and there are 678 parishes.

See E. Breese, *Kalendar of Gwynedd* (1873), and *The History of Powys Fadog*; E. Greenly, *The Geology of Anglesey*, vols. i. and ii., and *Memoir of Geological Survey* (1919).

ANGLESITE, a mineral consisting of lead sulphate, PbSO₄, crystallizing in the orthorhombic system, and isomorphous with barytes and celestite. It was first recognized as a mineral species, in 1783, by Dr. Withering, who discovered it in the Parys copper-mine in Anglesey; the name anglesite, from this locality, was given by F. S. Beudant in 1832. The crystals from Anglesey are small in size and simple in form; they are brownish-yellow in colour, owing to a stain of limonite. Crystals from some other localities, notably from Monteponi in Sardinia, are transparent and colourless, possessed of a brilliant adamantine lustre, and numerous faces. The hardness is 3 and the specific gravity 6.3. There are distinct cleavages parallel to the faces of the prism (110) and the basal plane (001), but these are not so well developed as in the isomorphous minerals barytes and celestite. Anglesite is a mineral of secondary origin, having been formed by the oxidation of galena in the upper parts of mineral lodes, where these have been affected by weathering processes.

ANGLI, **ANGLII** or **ANGLES**, a Teutonic people mentioned by Tacitus in his *Germania* (cap. 40) at the end of the 1st century, without precisely indicating their geographical position. With six other tribes, including the Varini (the Warni of later times), they

worshipped a goddess named Nerthus, whose sanctuary was situated on "an island in the Ocean." Ptolemy in his *Geography* (ii. 11. § 15), half a century later, locates them between the Rhine, or rather perhaps the Ems, and the Elbe, as one of the chief tribes of the interior. This indication cannot be correct. They seem to have lived on the coasts of the Baltic, probably in the southern part of the Jutish peninsula. Striking affinities to the cult of Nerthus are found in Scandinavian, especially Swedish and Danish, religion. The island of Nerthus was probably Sjaelland (Zealand).

According to Bede the Angli before they came to Britain dwelt in a land called Angulus, and similar evidence is given by the *Historia Brittonum*. King Alfred and the chronicler Aethelweard identified this place with the district which is now called Angel in the province of Schleswig (Slesvig). During the 5th century the Angli invaded Britain (see BRITAIN, Anglo-Saxon).

The large cremation cemetery at Borgstedterfeld, in the province of Schleswig between Rendsburg and Eckernförde, has yielded many urns and brooches closely resembling those found in heathen graves in England. The great deposits at Thorsbjærg (in Angel) and Nydam contained large quantities of arms, ornaments, articles of clothing, agricultural implements, etc., and in the latter case even ships. By the help of these discoveries we are able to reconstruct a fairly detailed picture of English civilization in the age preceding the invasion of Britain.

ANGLICAN COMMUNION, the name used to denote that branch of the Christian Church consisting of the various ecclesiastical bodies, throughout the world, in communion with the Church of England. (See ENGLAND, CHURCH OF.)

ANGLICANISM, a general term for the ecclesiastical system, organization, and doctrine of the Church of England and the churches throughout the world in communion with it. (See ENGLAND, CHURCH OF.)

ANGLIN, MARGARET (1876–), American actress, was born on April 3, 1876, at Ottawa, Canada. She was educated in the convents of Loretto abbey, at Toronto, and Sault Recollet, at Montreal. She studied drama at the Wheatcroft school in New York, and made her stage début in 1894 as Madeline West in Charles Frohman's presentation of *Shenandoah*. In 1898 she appeared as Roxane in *Cyrano de Bergerac*. From 1900 till 1903 she was the leading woman at the Empire theatre, and in 1903–04 acted with Henry Miller in *Camille*, *The Devil's Disciple*, and other plays. Her appearance in William Vaughn Moody's *The Great Divide*, in 1907, added lustre to her growing fame. In 1909 she produced and took the leading part in *The Awakening of Helena Richie*, the dramatization of Margaret Deland's novel of that name. In 1910 she first turned to the Greek tragedies, appearing in the open air theatre in Berkeley, Calif., in *Antigone*, and in 1913 in *Electra*. In 1916 she led 1,200 players in a presentation of *As You Like It* for the Shakespeare tercentenary celebration in Forest Park, St. Louis, Mo. In 1918 she gave *Medea* and *Electra* in New York, and in 1927 her third revival of *Electra* in the same city. Apart from her rendering of character in modern plays such as *The Woman of Bronze*, she is famous for her beautiful presentations of the Greek dramas and her faithful portrayal of their heroines.

ANGLING, the art or practice of the sport of catching fish by means of a baited hook or "angle" (from the Indo-European root *ank-*, meaning "bend"). It is among the most ancient of human activities, and may be said to date from the time when man was in the infancy of the stone age, eking out a precarious existence by the slaughter of any living thing which he could

reach with the rude weapons at his command. It is probable that attack on fishes was at first much the same as attack on animals: a matter of force rather than of guile, and conducted by means of a rude spear with a flint head. It is probable, too, that the primitive harpooners were not signally successful in their efforts, and so set their wits to work to devise other means of getting at the abundant food which waited for them in every piece of water near their caves. Observation would soon show them that fish fed greedily on each other and on other inhabitants of the water or living things that fell into it, and so, no doubt, arose the idea of entangling the prey by means of its appetite. Hence came the notion of the first hook, which, it seems certain, was not a hook at all but a "gorge," a piece of flint or stone which the fish could swallow with the bait but which it could not eject afterwards. From remains found in cave-dwellings and their neighbourhood in different parts of the world it is obvious that these gorges varied in shape, but in general the idea was the same: a narrow strip of stone or flake of flint, either straight or slightly curved at the ends, with a groove in the middle round which the line could be fastened. Buried in the bait it would be swallowed end first; then the tightening of the line would fix it cross-wise in the quarry's stomach or gullet and so the capture would be assured. The device still lingers in France and in a few remote parts of England in the method of catching eels which is known as "snigging." In this a needle buried in a worm plays the part of the prehistoric gorge.

The evolution of the fish-hook is still a matter of doubt. The gorge pure and simple is most efficient when perfectly straight, so the stages of its development into a curved hook—if it did so develop—are not easy to follow. But barbed harpoons of the later stone age have been found, and it is logical to conclude that once the custom of barbing fish-spears had been established, the same modification may easily have been applied to gorges also. In this case it would be found that many fish were hooked by the barb, and this form of angular hook, having the advantage of enabling fish to be "struck" without waiting for the bait to be gorged, would follow as a natural corollary to the barbed gorge. Hooks of this kind made out of thorn, and in one case out of an insect's leg, are still in use among primitive races. The transformation of this angular hook into a curved implement probably took place as a convenient method of manufacture when metal began to be used. Material used obviously varied in different parts of the world. The nature of the line or the rod that may have been used with these early hooks is largely a matter of conjecture. The first line was perhaps the tendril of a plant, the first rod possibly a sapling. But it is fairly obvious that the rod must have been suggested by the necessity of getting the bait out over obstacles which lay between the fisherman and the water, and that it was a device for increasing both the reach of the arm and the length of the line. It seems not improbable that the rod very early formed a part of the fisherman's equipment.

Literary History.—From prehistoric times down to comparatively late in the days of chronicles, angling appears to have remained a practice; its development into an art or sport is a modern idea. In the earliest literature references to angling are not very numerous, but there are passages in the Old Testament which show that fish-taking with hook as well as net was one of the common industries in the East, and that fish, where it was obtainable, formed an important article of diet. In Numbers (xi. 5) the children of Israel mourn for the fish which they "did eat in Egypt freely." So much too is proved by the monuments of Egypt; indeed more, for the figures found in some of the Egyptian fishing pictures using short rods and stout lines are sometimes attired after the manner of those who were great in the land. This indicates that angling had already, in a highly civilized country, taken its place among the methods of diversion at the disposal of the wealthy, though from the uncompromising nature of the tackle depicted and the apparent simplicity of the fish it would scarcely be safe to assume that in Egypt angling arrived at the dignity of becoming an "art." In Europe it took very much longer for the taking of fish to be regarded even as an amusement, and the earliest references to it in the Greek and

Latin classics are not very satisfying to the sportsman. There is, however, a passage in the *Odyssey* (xii. 247) which is of considerable importance, as it shows that fishing with rod and line was well enough understood in early Greece to be used as a popular illustration. It occurs in the well-known scene where Scylla seizes the companions of Odysseus out of the ship and bears them upwards, just as "some fisher on a headland with a long rod" brings small fishes gasping to the shore. Another important, though comparatively late, passage in Greek poetry is the 21st idyll of Theocritus. In this the fisherman Asphalion relates how in a dream he hooked a large golden fish and describes graphically, albeit with some obscurity of language, how he "played" it. Asphalion used a rod and fished from a rock, much after the manner of the Homeric angler. Among other Greek writers, Herodotus has a good many references to fish and fishing; the capture of fish is once or twice mentioned or implied by Plato, notably in the *Laws* (vii. 823); Aristotle deals with fishes in his *Natural History*; and there are one or two fishing passages in the anthology. But in Greek literature as a whole the subject of angling is not at all prominent. In writers of late Greek, however, there is more material. Plutarch, for instance, gives us the famous story of the fishing match between Antony and Cleopatra, which has been utilized by Shakespeare. Moreover, it is in Greek that the first complete treatise on fishing which has come down to us is written, the *Halieutica* of Oppian (c. A.D. 169). It is a hexameter poem in five books with perhaps more technical than sporting interest, and not so much even of that as the length of the work would suggest. Still it contains some information about tackle and methods, and some passages describing battles with big fish, in the right spirit of enthusiasm. Also in Greek is what is famous as the first reference in literature to fly-fishing, in the 15th book of Aelian's *Natural History* (3rd century A.D.). It is there described how the Macedonians captured a certain spotted fish in the river Astraeus by means of a lure composed of coloured wool and feathers, which was presumably used in the manner now known as "dapping." That there were other Greek writers who dealt with fish and fishing and composed "halieutics" we know from Athenaeus. In the first book of his *Deipnosophistae* he gives a list of them.

In Latin literature allusions to angling are more numerous than in Greek, but on the whole they are unimportant. Part of a poem by Ovid, the *Halieuticon*, composed during the poet's exile at Tomi after A.D. 9, still survives. In other Roman writers the subject is treated only by way of allusion or illustration. Martial, however, provides, among other passages, what may perhaps be entitled to rank as the earliest notice of private fishery rights—the epigram *Ad Piscatorem*, which warns would-be poachers from casting a line in the Baian lake. Pliny the elder devoted the ninth book of his *Natural History* to fishes and water-life, and Plautus, Cicero, Catullus, Horace, Juvenal, Pliny the younger and Suetonius all allude to angling here and there. Agricultural writers, too, such as Varro and Columella, deal with the subject of fish-ponds and stews rather fully. Later than any of these, but still just included in Latin literature, we have Ausonius (c. A.D. 320) and his well-known idyll the *Mosella*, which contains a good deal about the fish of the Moselle and the methods of catching them.

Post-classical Literature.—As to what happened in the world of angling in the first few centuries of the Christian era we know little. It may be inferred, however, that both fish and fishermen occupied a more honourable position in Christendom than they ever did before. The prominence of fishermen in the gospel narratives would in itself have been enough to bring this about, but it also happened that the Greek word for fish, ΙΧΘΥΣ, had an anagrammatic significance which the devout were not slow to perceive. The initials of the word resolve into what is practically a confession of faith, Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτὴρ (Jesus Christ, Son of God, Saviour). It is therefore not surprising that we find the fish very prominent as a sacred emblem in the painting and sculpture of the primitive church, or that Clement of Alexandria should have recommended it, among other things, as a device for signet rings or seals. The fisherman too is frequently

represented in early Christian art, and it is worthy of remark that he more often uses a line and hook than a net. The references to fish and fishing scattered about in the writings of the early fathers for the most part reflect the two ideas of the sacredness of the fish and divine authorization of the fisherman; the second idea certainly prevailed until the time of Izaak Walton, for he uses it to justify his pastime. It is also not unlikely that the practice of fasting (in many cases fish was allowed when meat was forbidden) gave the art of catching fish additional importance. It seems at any rate to have been a consideration of weight when sites were chosen for monasteries in Europe, and in many cases when no fish-producing river was at hand the lack was supplied by the construction of fish-ponds. Despite all this, however, save for an occasional allusion in the early fathers, there is hardly a connecting link between the literature of pagan Rome and the literature that sprang up on the invention of printing.

The first printed book on angling (a translation of Oppian, 1478, excepted) was a little volume printed in Antwerp probably in 1492 at the press of Matthias van der Goes. In size it is little more than a pamphlet, and it treats of birds as well as fish: *Dit Boecxken leert hoe men mach Voghelen . . . ende . . . visschen vangen metten kanden. Ende oeck andersins. . .* ("This book teaches how one may catch birds . . . and . . . fish with the hands, and also otherwise.") Only one copy apparently survives, in the Denison library, and a translation privately printed in 1872 was limited to 25 copies. At least two other editions of the book appeared in Flemish, and it also made its way, in 1502, to Germany, where, translated and with certain alterations and additions, it seems to have been re-issued frequently. Next in date comes the famous *Treatyse of Fysshynge wyth an Angle*, printed at Westminster by Wynkyn de Worde in 1496 as a part of the second edition of the *Boke of St. Albans*. The treatise is almost certainly a compilation from some earlier work on angling ("bokes of credence" are mentioned in its text), possibly from a ms. of the earlier part of the 15th century, of which a portion is preserved in the Denison collection. This was published in 1883 by Mr. Thomas Satchell under the title *An Older Form of the Treatyse of Fysshynge wyth an Angle*. But it is also possible that a still older work was the parent of both books, for it has been held that the ms. is an independent version. However this may be, it is certain that the treatise itself has been the parent of many other works. Many of the instructions contained in it are handed down from generation to generation with little change except in diction. Especially is this the case with the list of trout-flies, a meagre 12, which survives in many fishing books until well into the 18th century.

From the beginning of the 16th century the fisherman's library begins to grow apace, as, though books solely devoted to fishing are not yet frequent, works on husbandry and country pursuits almost all contain something on the subject. In Italy the fisherman and his occupation apparently were considered poetically; the word *pescatore* or its cognates are common on Italian 16th and 17th century title-pages, though in many instances the fulfilment of the implied promise is not adequate, from an angler's point of view. From the pages of *Bibliotheca Piscatoria* a fairly long list of Italian writers could be gleaned. Among them may be mentioned Sannazaro (*Piscatoria*, etc., Rome, 1526) and Andrea Calmo (*Rime pescatorie*, Venice, 1557). A century later was Parthenius, who published a volume of *Halieutica* at Naples. This writer has an amusing reference to the art of "tickling" trout as practised in Britain. In Germany, as has been shown, the original little Flemish treatise had a wide vogue in the 16th century, and fishing played a part in a good many books on husbandry such as that of Conrad Heresbach (1570). Fish and fish-ponds formed the main topic of a Latin work by Dubravius (1552), while Gesner in the middle of the 16th and Aldrovandi at the beginning of the 17th centuries wrote at length on the natural history of fishes. In France there were editions, now very rare, of the Flemish treatise published at Lyons about 1530, and *Les Pescheries* of Chris. de Gamon (Lyons, 1599) and *Le Plaisir des champs* of Cl. Gauchet (Paris, 1604) deserve to be noted. *Les Ruses innocentes* by François Fortin, first published

at Paris in 1600, and several times in later editions, is characterized by Messrs. Westwood and Satchell as "on the whole the most interesting contribution made by France to the literature of angling."

Modern Literature.—In 1600 appeared John Taverner's *Certain Experiments concerning Fish and Fruite*, and after this the period of angling literature proper begins. The *Secrets of Angling* (1613), by J(ohn) D(ennys), Esq., is one of the most important volumes in the angler's library, both on account of the excellence of the verse in which it is written and also on account of its practical value. Gervase Markham, "the first journalist," as he has been called, published his first book of husbandry at the same date, and, as in most of his many books on the same subject, devoted a certain amount of space to fishing. But Markham gathered his materials in a rather shameless manner and his angling passages have little originality. Thomas Barker's *The Art of Angling* (1st ed., 1651) takes a more honourable position, and received warm commendation from Izaak Walton himself, who followed it in 1653 with *The Compleat Angler*. So much has been written about this treasured classic that it is only necessary to indicate its popularity here by saying that its editions occupy some 20 pages in *Bibliotheca Piscatoria* (1883), and that since that work was published at least 40 new editions have to be added to the list. During Walton's life-time the book ran through five editions, and with the fifth (1676) was incorporated Charles Cotton's second part, the "instructions how to angle for a trout or grayling, in a clear stream." In some cases too there was added a third book, the fourth edition of *The Experienced Angler*, by Robert Venables (1st ed., 1662). The three books together bore the title of *The Universal Angler*.

A few other notable books of the century call for enumeration, *The Gentleman's Recreation* by Nicholas Cox (1674), Gilbert's *The Angler's Delight* (1676), Chetham's *Vade-Mecum* (1681), *The Complete Troller* by Robert Nobbes (1682), R. Franck's *Northern Memoirs* (1694), and *The True Art of Angling* by J. S. (1696). Of these Chetham, Nobbes, Franck and J. S. have the merit of considerable originality. Franck has gained some notoriety by his round abuse of Walton. In the 18th century among others we find *The Secrets of Angling* by C. G. (1705), Robert Howlett's *The Angler's Sure Guide* (1706), *The Whole Art of Fishing* (1714), *The Compleat Fisherman* by James Saunders (1724), *The Art of Angling* by R. Brookes (1740), another book with the same title by R. and C. Bowlker (Worcester, c. 1750), *The Complete Sportsman* by Thomas Fairfax (c. 1760), *The Angler's Museum* by T. Shirley (1784), and *A Concise Treatise on the Art of Angling* by Thomas Best (1787). Of these only Saunders', Bowlker's and Best's books are of much importance, the rest being for the most part "borrowed." One volume of verse in the 18th century calls for notice, Moses Browne's *Piscatory Eclogues* (1729).

With the 19th century angling literature becomes too big a subject to be treated in detail, and it is only possible to glance at a few of the more important books and writers. Daniel's *Rural Sports* appeared in 1801; it is a treasure-house of odd facts. In 1828 Sir Humphry Davy published his famous *Salmonia*, which was reviewed in the *Quarterly* by Sir Walter Scott. At about this time too were appearing the "Noctes Ambrosianae" in *Blackwood's Magazine*. Christopher North (Prof. Wilson) often touched upon angling in them, besides contributing a good many angling articles to the magazine. In 1835 that excellent angling writer Thomas Tod Stoddart began his valuable series of books with *The Art of Angling as Practised in Scotland*. In 1839 he published *Songs and Poems*, among which are pieces of great merit. During this period, too, first appeared, year by year, the *Newcastle Fishers' Garlands*, collected by Joseph Crawhall afterwards and republished in 1864. These border verses, like Stoddart's, have often a genuine ring about them which is missing from the more polished effusions of Gay and Thomson. Alfred Ronalds's *The Fly-Fisher's Entomology* (1st ed., 1836) was a publication of great importance, for it marked the beginning of the scientific spirit among trout-fishers. It ran through many editions and is still a valuable book of reference. A step in angling

history is also marked by George Pulman's *Vade Mecum of Fly-fishing for Trout* (1841), for it contains the first definite instructions on fishing with a "dry fly." Another is marked by Hewett Wheatley's *The Rod and the Line* (1849), where is to be found the earliest reference to the "eyed" hook. Yet another is marked by W. C. Stewart's *The Practical Angler* (1857), in which is taught the new doctrine of "up-stream" fishing for trout. This is a book of permanent value. Among the many books of this period Charles Kingsley's *Miscellanies* (1859) stands out, for it contains the immortal "Chalk-Stream Studies." The work of Francis Francis begins at about the same time, though his *A Book on Angling*, which is still one of the most valuable text-books, was not first published till 1867. Among other English writers worthy of mention were William Senior, John Bickerdyke and F. M. Halford. (See further bibliography *ad fin.*). In America the latter half of the 19th century produced a good deal of fishing literature, much of it of a high standard. *I go a-Fishing* by Dr. W. C. Prime (1873), *Fishing with the Fly* by C. F. Orvis, A. Nelson Cheney and others (1883), *The American Salmon Fisherman* and *Fly Rods and Fly Tackle* by H. P. Wells, *Little Rivers* and other books by the Rev. H. Van Dyke—these are only a few specially distinguished in style and matter. Germany and France have not contributed so largely to the modern library, but in the first country we find several useful works by Max von dem Borne, beginning with the *Handbuch der Angelfischerei* of 1875, and there are a good many other writers who have contributed to the subject, while in France there are a few volumes on fishing by different hands. The most noticeable is M. G. Albert Petit's *La Truite de rivière* (1897), an admirable book on fly-fishing.

During the present century the output of angling books has been too great for more than a selected list to be attempted, which will be found in the bibliography below, but mention may just be made here of one or two outstanding volumes that have appeared. There is, first of all, Mr. William Radcliffe's *Fishing from the Earliest Times* (2nd ed. 1926), in which the author has collected a mass of references to angling dating from cave frescoes, and implements of the stone age, through the dawn of history, down to about A.D. 500 and discusses the allusions to fishing in classical literature, on Egyptian monuments and Chinese records, and is the only attempt as yet made to compile a complete historical record of the sport. In 1907 Mr. W. L. Calderwood, the inspector of fisheries for Scotland, published his *The Life of the Salmon*, which is perhaps the most authoritative work on the knowledge of the salmon which modern scientific research has produced. Mr. Martin E. Mosely published *The Dry Fly Fisherman's Entomology* in 1921, a continuation of Mr. Halford's works on the same subject; Mr. G. E. M. Skues has produced *Minor Tactics of the Chalk Stream* (3rd ed. 1924) and *The Way of a Trout with a Fly*, which describe, in effect, a method of applying to the wet fly the scientific knowledge on which dry-fly fishing is founded. *A Bibliography of Fishes* by Bashford Dean and others published by the American Museum of Natural History was completed in three volumes in 1923, and is the biggest work of its kind ever undertaken. In France a notable contribution to fishing literature is Lt.-Col. Vavon's *La Truite: ses mœurs: L'Art de Pêcher*, which appeared in a limited edition in 1927. In it the author has collected the modern knowledge of the life history, structure and habits of the trout, and presents his recommendations for methods of capture as a logical deduction from its past history and propensities. Though it does not provide any really new information it is one of the most important books on fishing which France has yet produced.

Modern Conditions.—In the modern history of angling there are one or two features that should be touched upon. A discovery in the natural history of the salmon by H. W. Johnson (*The Field*, Oct. 29, 1904) following on the work of the 17th-century Dutch naturalist, Leeuwenhoek, that the age and past history of a fish can be read on its scales, has enormously increased our knowledge of the life history of migratory salmonidae. Briefly, the discovery was that a fish, without adding to the number of its scales, accommodates its increasing size by adding

layers to them, each layer on completion turning up slightly at its edge and thus forming a series of ridges which can easily be seen under a low-powered microscope. In summer when food is plentiful the rings thus formed are wide, while in winter owing to the comparative scarcity of food, and probably to the extra amount of nourishment absorbed in maintaining bodily warmth, the resulting rings are narrow. Thus a salmon's scale shows a

SKETCH OF SALMON SCALE FROM A SPRING FISH WITH SPAWNING MARK. ONLY A FEW OF THE RINGS ARE SHOWN

series of wide rings (summer zone) followed by a series of narrow rings (winter band) the two together forming one year in the fish's life. When a salmon enters a river for the purpose of spawning and loses condition, the edge of the scale (the greater part of which is embedded in the skin) is absorbed, and the outermost rings disappear. When scale formation starts again on recovery from spawning these rings are not replaced but new ones are laid down, the rough broken edges of the rings which have disappeared forming an uneven dark mark round the scale known as the "spawning mark." The information gained by reading the scales, supplemented by additional information from marking fish (with a metal label or similar device) and returning them to the water, has profoundly modified our ideas of the life of the salmon. Grilse (immature salmon) at one time regarded as a separate species, and later believed to be fish which had spent only a few months in the sea, is now the name given to salmon which have spent only one year (none spend less) and a few months in the sea before returning to fresh water. It has also been shown that the length of a salmon's "parr" life in fresh water has a considerable effect on the length of its sojourn in the sea, the rule being, roughly, that the longer a parr takes in growing to the smolt stage before migration the shorter will be its stay in salt water and the greater likelihood of its return to the river as a grilse instead of a larger and more profitable "spring" or "summer" fish (fish which have spent two or more years in the sea). It is now known, too, that very few fish return to spawn a second time, while a fish which has four or more spawning marks on its scales is worth recording as a phenomenal capture. Knowledge of sea trout, though increasing rapidly, has not kept pace with the knowledge of salmon, but the method of reading their scales is the same, though the interpretation of them is more difficult, owing to their habit of returning to fresh water for purposes other than spawning. Attempts have also been made to apply the same system to fresh-water fish other than the salmon family, but though some progress has been made it is not yet possible to interpret their rings with the same accuracy as with salmon and trout. All European trout, whether "sea," "brown" or

any of the numerous variations that used to be listed as subspecies are now regarded as one and the same species (*S. trutta*) there being no discoverable structural difference, according to the latest scientific investigations. Trout varying in colour owing to quality of food, water, or other local conditions are regarded simply as "strains" of the same species.

The great increase in the number of fishermen has had several results. One is a corresponding increase in the difficulty of obtaining fishing, and a notable rise in the value of rivers, especially those which are famed for salmon and trout. Salmon-fishing now may be said to have become a pastime of the rich, and there are signs that trout-fishing will before long have to be placed in the same exclusive category, while even the right to angle for less-esteemed fish will eventually be a thing of price. The development is natural, and it has naturally led to efforts on the part of the angling majority to counteract, if possible, the growing difficulty. These efforts have been directed chiefly in two ways, one the establishment of fishing clubs, the other the adoption of angling in salt water. The fishing club of the big towns was originally a social institution, and its members met together to sup, converse on angling topics and perhaps to display notable fish that they had caught. Later, however, arose the idea that it would be a convenience if a club could give its members privileges of fishing as well as privileges of reunion. So it comes about that all over the United Kingdom, in British colonies and dependencies, in the United States, and various countries of Europe, fishing clubs rent waters, undertake preservation and restocking and generally lead an active and useful existence. It is a good sign for the future of angling and anglers that they are rapidly increasing in number. One of the oldest fishing clubs, if not the oldest, was the Schuylkill club, founded in Pennsylvania in 1732. An account of its history was published in Philadelphia in 1830. Among the earliest clubs in London are to be numbered such societies as The True Waltonians, The Piscatorial, The Friendly Anglers and The Gresham, which are still flourishing. A certain amount of literary activity has been observable in the world of angling clubs, and several volumes of "papers" are on the records. Most noticeable perhaps are the three volumes of *Anglers' Evenings* published in 1880-94, a collection of essays by members of the Manchester Anglers' association. The other method of securing a continuance of sport, the adoption of sea-angling as a substitute for fresh-water fishing, is quite a modern thing. Within the memory of men still young the old tactics of hand-line and force were considered good enough for sea fish. Now the fresh-water angler has lent his centuries of experience in deluding his quarry; the sea-angler has adopted many of the ideas presented to him, has modified or improved others, and has developed the capture of sea-fish into a science almost as subtle as the capture of their fresh-water cousins.

During the last few years a greater development still has taken place in the capture of exceptionally large fish—sharks, swordfish, tuna, etc.—running up to weights of several hundred pounds and now known under the name of big-game fishing. This fishing was first inaugurated as a separate branch of the sport by the Tuna club of Santa Catalina. The discovery of tuna grounds on the coast of Nova Scotia, where subsequently Mr. Zane Grey took the record tuna, weighing 758 lb., with rod and line, widened the geographical scope of the fishing, since when the north shore of the northern island of New Zealand has provided some wonderful takes of "marlin" and "broadbill" swordfish, and Mako shark, and is now by way of being the most notable big-game fishing ground in the world. It is probable that the neighbourhood of Hongkong and off the east coast of Japan will also develop into fishing centres for the sport, since some of the species in the New Zealand coastal currents are known to be present in these waters also. The spawning grounds of tuna are in the Mediterranean, but since, like many other fish, they seem to cease feeding on the approach of the spawning season, rod and line fishing there is little developed, but they have been caught at times in the North sea and a capture (August 1927) of large tuna (over 500 lb.) by Danish anglers in the Kattegat, off the coast of Denmark, is an indication that this fishing may be within reach of British coasts. Up to the present, however, British anglers

regard the conger, skate, halibut and tope (*Galeus vulgaris*), a small species of shark, allied to the dogfishes, as the "big-game" of home waters. Several important fresh-water species have also become a later part of angling enterprise, notably the dorado of South American rivers, the "Euphrates salmon" of the Euphrates watershed, a fish resembling the mahseer in character but reaching much greater weights, and the Nile perch and tiger fish of the big African rivers. One more modern feature, which is also a result of the increase of anglers, is the great advance made in fish-culture, fish-stocking and fish-acclimatization during the last half-century. Fish-culture is now a recognized industry; every trout-stream of note and value is restocked from time to time as a matter of course; salmon-hatcheries are numerous, though their practical utility is still a debated matter, in Great Britain at any rate; coarse fish are also bred for purposes of restocking; and, lastly, it is now considered a fairly simple matter to introduce fish from one country to another, and even from continent to continent. In England the movement owes a great deal to Francis Francis, who, though he was not the earliest worker in the field, was among the first to formulate the science of fish-breeding; his book *Fish-Culture*, first published in 1863, still remains one of the best treatises on the subject. In the United States, where fishery science has had the benefit of generous governmental and official support and countenance and so has reached a high level of achievement, Dr. T. Garlick (*The Artificial Reproduction of Fishes*, Cleveland, 1857) is honoured as a pioneer. On the continent of Europe the latter half of the 19th century saw a very considerable and rapid development in fish-culture, but until comparatively recently the propagation and care of fish in most European waters have been considered almost entirely from the point of view of the fish-stew and the market. As to what has been done in the way of acclimatization it is not necessary to say much. Trout (*Salmo fario*) were introduced to New Zealand in the late '60s from England; in the '80s rainbow trout (*S. irideus*) were also introduced from California; now New Zealand provides the finest trout-fishing of its kind in the world. The quinnat salmon from the Pacific coast of North America and the Atlantic salmon (*S. salar*) from European waters have also been acclimatized in New Zealand, but whereas the quinnat has adopted the life habit of its original home, the Atlantic salmon has shown peculiarities of behaviour and development that have for some time puzzled both anglers and scientists. The earlier attempts to introduce it were failures, possibly on account of the comparatively high temperature of the coastal waters as compared with the original habitat in the northern hemisphere; but the more recent attempts in the early years of the present century in Lake Te Anau and the river Waiau in the south island have produced a considerable stock of fish, which are evidently spawning in those waters and may be considered, from that point of view, to have acclimatized themselves. They, however, show several peculiarities which differentiate them from the *S. salar* of Europe. The first and most noticeable is the fact that mature fish feed regularly in fresh water, even when approaching the spawning period, a habit unknown among sea-going *salar*, either in Europe or America. Although they descend to tidal water no specimen has, as yet, been caught in the sea out of reach of tidal influence. Their size, considering their age, is small, the largest fish recorded being little more than 20 lb. and the majority even of the larger fish running from 12 lb. to 14 lb. An examination of their scales shows that they give no sign of the customary wide zones denoting rich sea-feeding, but that, on the contrary, the arrangement of the rings bears a strong resemblance to the landlocked *salar* of North America. It is considered by Tate Regan, W. L. Calderwood, Arthur Hutton and other authorities (*Salmon and Trout Magazine*, July 1927), that these fish have adopted a fresh-water habit, and have become, in effect, voluntarily landlocked. The quinnat, on the other hand, seem to have the same sea-going habit as the fish of American waters. American trout of different kinds have been introduced into England, and brown trout have been introduced into America; but neither innovation can be said to have been an unqualified success, though the rainbow has established itself firmly in some waters of the United Kingdom.

It is still regarded with some suspicion, as it has a tendency to wander from waters which do not altogether suit it. For the rest, trout have been established in Ceylon, in Kashmir, in South Africa (where carp have also been introduced with very surprising results, being now regarded almost as a nuisance), and in British Central Africa. In fact the possibilities of acclimatization are so great that it seems probable that in time no river of the civilized world capable of holding trout will be without them.

METHODS AND PRACTICE

Angling falls into two main divisions, fishing in fresh water and fishing in the sea. The two branches of the sport have much in common, and sea-angling is really little more than an adaptation of fresh-water methods to salt-water conditions. Therefore it will not be necessary to deal with it at great length and it naturally comes in the second place. Angling in fresh water is, again, divisible into three principal parts: fishing on the surface, *i.e.*, with the fly; in mid-water, *i.e.*, with a bait simulating the movements of a small fish or with the small fish itself; and on the bottom with worms, paste or one of the many other baits which experience has shown that fish will take. With the premise that it is not intended here to go into the minutiae of instruction which may more profitably be discovered in the many works of reference cited at the end of this article, some account of the subdivisions into which these three styles of fishing fall may be given.

FRESH-WATER FISHING

Fly-fishing.—Fly-fishing is the most modern of them, but it is the most highly esteemed, principally because it is the method *par excellence* of taking members of the most valuable sporting family of fish, the *Salmonidae*. It may roughly be considered under three heads: the use of the "wet" or sunk fly, of the "dry" or floating fly, and of the natural insect. Of these the first is the most important, for it covers the widest field and is the most universally practised. There are few varieties of fish which may not either consistently or occasionally be taken with the sunk fly in one of its two forms. The large and gaudy bunch of feathers, silk and tinsel with which salmon, very large trout, black bass and occasionally other predacious fish are taken is not, strictly speaking, a fly at all. It rather represents, if anything, some small fish or subaqueous creature on which the big fish is accustomed to feed, and it may conveniently receive the generic name of salmon-fly. The smaller lures, however, which are used to catch smaller trout and other fish that habitually feed on insect food are in most cases intended to represent that food in one of its forms and are entitled to the name of "artificial flies." The dry- or floating-fly is simply a development of the imitation theory, and has been evolved from the wet-fly in course of closer observation of the habits of flies and fish in certain waters. Both wet- and dry-fly methods are really a substitute for the third and oldest kind of surface-fishing, the use of a natural insect as a bait. Each method is referred to incidentally below.

Spinning, etc.—Mid-water fishing, as has been said, broadly consists in the use of a small fish, or something that simulates it, and its devices are aimed almost entirely at those fish which prey on their fellows. Spinning, live-baiting and trolling¹ are these devices. In the first a small dead fish or an imitation of it made in metal, india-rubber, or other substance, is caused to revolve rapidly as it is pulled through the water, so that it gives the idea of something in difficulties and trying to escape. In the second a small fish is put on the angler's hook alive and conveys the same idea by its own efforts. In the third a small dead fish is caused to dart up and down in the water without revolving; it conveys the same idea as the spinning fish, though the manipulation is different.

Bottom-fishing.—Bottom-fishing is the branch of angling which is the most general. There is practically no fresh-water fish that will not take some one or more of the baits on the angler's list if they are properly presented to it when it is hungry.

¹Trolling is very commonly confused in angling writing and talk with *trailing*, which simply means drawing a spinning-bait along behind a boat in motion.

Usually the baited hook is on or near the bottom of the water, but the rule suggested by the name "bottom-fishing" is not invariable and often the bait is best used in mid-water; similarly, in "mid-water fishing" the bait must sometimes be used as close to the bottom as possible. Bottom-fishing is roughly divisible into two kinds, float-fishing, in which a bite is detected by the aid of a float fastened to the line above the hook and so balanced that its tip is visible above the water, and hand-fishing, in which no float is used and the angler trusts to his hand to feel the bite of a fish. In most cases either method can be adopted and it is a matter of taste, but broadly speaking the float-tackle is more suited to water which is not very deep and is either still or not rapid. In great depths or strong streams a float is difficult to manage.

THE FISH

It is practically impossible to classify the fish an angler catches according to the methods which he employs, as most fish can be taken by at least two of these methods, while many of those most highly esteemed can be caught by all three. Sporting freshwater fish are therefore treated according to their families and merits from the angler's point of view, and it is briefly indicated which method or methods best succeed in pursuit of them.

Salmon.—First in importance come migratory *Salmonidae*, and at the head of them the salmon (*Salmo salar*), which has a twofold reputation as a sporting and as a commercial asset. The salmon fisheries of a country are a very valuable possession, but it is only comparatively recently that this has been realized and that salmon rivers have received the legal protection which is necessary to their well-being. Even now it cannot be asserted that in England the salmon question, as it is called, is settled. Partly owing to former ignorance of the life-history of the fish, partly owing to the difficulty of reconciling the opposed interests of commerce and sport, the problem as to how a river should be treated remains only partially solved, though it cannot be denied that there has been a great advance in the right direction. The life-history of the salmon, so far as it concerns the matter in hand, may be very briefly summed up. It is bred in the rivers and fed in the sea. The parent fish ascend in late autumn as high as they can get, the ova are deposited on gravel shallows, hatching out in the course of a few weeks into parr. The infant salmon remains in fresh water at least one year, generally two years, without growing more than a few inches, and then about May assumes what is called the smolt-dress; that is to say, it loses the dark parr-bands and red spots of infancy and becomes silvery all over. After this it descends without delay to the sea, where it feeds to such good purpose that in a year it has reached a weight of several pounds, and it may then reascend as a grilse. If the fish survives the perils of its first ascent and spawning season and as a kelt or spawned fish gets down to the sea again, it may come up a second time as a salmon some pounds heavier.

But in fact only a small percentage of salmon survive for a second spawning in the rivers of Great Britain though on the east coast of Canada a much larger percentage do so. The various "runs" of fish which occur in all salmon rivers do not consist of fish about to spawn for the first, second or third time, but of fish which have spent one, two or three years in the sea after their first descent to salt water. These runs are now for statistical purposes reckoned by the number of *winters* spent in the sea, the fish whose scales end in a winter band being known as "spring" fish, and those whose scales end in a summer zone as "summer" fish. The classes are: grilse (one winter), small spring and summer (two winters), large ditto (three winters), very large ditto (four winters). Why some fish are much heavier than others of the same age, what their mode of life is in the sea, why some run up in spring and summer when the breeding season is not till about November or December, whether they were originally sea-fish or river-fish—these and other similar questions await a conclusive answer. One principal fact, however, stands out amid the uncertainty, and that is that without a free passage up and down unpolluted rivers and without protection on the spawning beds salmon have a very poor chance of perpetuating their species. Economic prudence dictates therefore that every

year a considerable proportion of running salmon should be allowed to escape the dangers that confront them in the shape of nets, obstructions, pollutions, rods and poachers. And it is in the adjustment of the interests which are bound up in these dangers (the last excepted; officially poachers have no interests, though in practice their plea of "custom and right" has too often to be taken into consideration) that the salmon question consists. To secure a fair proportion of fish for the market, a fair proportion for the rods and a fair proportion for the *redds*, without unduly damaging manufacturing interests, this is the object of those who have the question at heart, and with many organizations and scientific observers at work it should not be long before the object is attained. It is very largely due to the efforts of anglers that the matter has gone so far.

Whether salmon feed in fresh water is another question of peculiar interest to anglers, for it would seem that if they do not then the whole practice of taking them must be an anomaly. Champions have arisen on both sides of the argument, some, scientists, asserting that salmon (parr and kelts excluded, for both feed greedily as opportunity occurs) do not feed; others, mostly anglers, maintaining strongly that they do, and bringing as evidence their undoubted and customary capture by rod and line, not only with the fly, but also with such obvious food-stuffs as dead baits, worms and prawns. On the other side it is argued that food is never found inside a salmon after it has been long enough in a river to have digested its last meal taken in salt water. The very few instances of food found in salmon which have been brought forward to support the contrary opinion are, in the scientific view, to be regarded with great caution.

It has been lately found, however, that there is often a kind of slime in the stomach of captured salmon, consisting of food juices, and there is a certain amount of evidence that salmon in fresh water have a habit of chewing food and then rejecting it. From this it has been suggested that while salmon may take food in fresh water they swallow merely the essence of it and reject the valueless remains. Such a theory might help to reconcile both sets of observations. At the same time, since many good salmon rivers contain only sufficient food to maintain a meagre stock of undersized trout, it is evident that the food a salmon can get in such water would only be a trifle in comparison with the sustenance necessary for so large a fish. Dr. J. Kingston Barton, in the first of the two volumes on "Fishing" (*Country Life* series), has suggested that after exertion, such as that entailed by running from pool to pool during a spate, the fish may feel a very transient hunger and be impelled thereby to snap at anything in its vicinity which looks edible. The fact that the angler's best opportunity is undoubtedly when salmon have newly arrived in a pool, supports this contention. The longer they are compelled to remain in the same spot by lack of water the worse becomes the prospect of catching them, and "unfishable" is one of the expressive words which fishermen use to indicate the condition of a river during the long periods of drought which too often distinguish the sport.

Salmon Tackle and Methods.—It is when the drought breaks up and the long-awaited rain has come that the angler has his chance and makes ready his tackle, against the period of a few days (on some short streams only a few hours) during which the water will be right; *right* is a very exact term on some rivers, meaning not only that the colour of the water is suitable to the fly, but that its height shall be within an inch or two of a given mark, prescribed by experience. As to the tackle which is made ready, there is, as in most angling matters, divergence of opinion. Salmon fly-rods are now made principally of two materials, greenheart and split-cane; the former is less expensive, the latter is more durable; it is entirely a matter of taste which a man uses, but the split-cane rod is now more in favour. It has been a matter of debate whether it is better built with a core of steel running from butt to tip and known as a "steel centre." How long the rod shall be is also a matter on which anglers differ, but from 16ft. to 17ft. 6in. represents the limits within which most rods are preferred. The tendency is to reduce rather than to increase the length of the rod, which

TYPES OF FISHING REELS AND FLIES

- Steps taken in making a dry fly. A peacock's quill, a cock's hackle and a starling's wing feathers are all used in making a dry fly
- The reel shown in position on the rod. The butt end of the rod is attached to the angler's seat when extra leverage is needed
- Left to right: A spoon; silk phantom minnow as used on River Wye, England; Wagtail; an archer flight for mounting a natural dead minnow
- Left, reading up: trout fly, old style wet fly; trout fly, modern wet fly; trout fly with upright wings; trout fly, modern nymph. Upper right, salmon fly, old type, heavily dressed; centre, salmon fly, modern, lightly dressed; right centre, May fly, spent gnat; lower right, May fly, green drake
- Casting reel. The gearing between handle and drum compensates for the small diameter of the spool
- Fly fishing reel. This type, with narrow drum, is used for trout. A similar reel with larger drum is used for salmon

may be accounted for by the adoption of a heavy line. Early in the 19th century anglers used light-topped rods of 20ft. and even more, and with them a light line composed partly of horse-hair; they thought 60ft. with such material a good cast. Modern experience, however, has shown that a shorter rod with a heavier top will throw a heavy dressed silk line much farther with less exertion. Ninety feet is now considered a good fishing cast, while many men can throw a great deal more. In the United States, where rods have long been used much lighter than in England, the limits suggested would be considered too high. Single-handed rods are in common use there and are becoming popular elsewhere. The variety of reels, lines, gut collars and other forms of tackle which is now presented to the angler's consideration and for his bewilderment is too wide a subject to be touched upon here. Something, however, ought to be said about flies. One of the perennially fruitful topics of enquiry is what the fish takes a salmon-fly to be. Beyond a fairly general admission that it is regarded as something endowed with life, perhaps resembling a remembered article of marine diet, perhaps inviting gastronomic experiment, perhaps merely irritating and rousing an impulse to destroy, the discussion has not reached any definite conclusion. But more or less connected with it is the controversy as to variety of colour and pattern. Some authorities hold that a great variety of patterns with very minute differences in colour and shades of colour is essential to complete success; others contend that salmon do not differentiate between nice shades of colour, that they only draw distinctions between flies, broadly, as being light, medium or dark in general appearance, and that the size of a fly rather than its colour is the important point for the angler's consideration. Others, again, go some way with the supporters of the colour-scheme and admit the efficacy of flies whose general character is red, or yellow, or black, and so on. The opinion of the majority, however, is probably based on past experience, and a man's favourite flies for different rivers and conditions of water are those with which he or someone else has previously succeeded. It remains a fact that in most fly-books great variety of patterns will be discoverable, while certain old standard favourites, such as the Jock Scott, Durham Ranger, Silver Doctor, and Thunder and Lightning, will be prominent. Coming out of the region of controversy it is a safe generalization to say that the common rule is: big flies for spring fishing when rivers are probably high, small flies for summer and low water, and flies medium or small in autumn according to the conditions. Spring fishing is considered the cream of the sport. Though salmon are not as a rule so numerous or so heavy as during the autumn run, and though kelts are often a nuisance in the early months, yet the clean-run fish of February, March or April amply repays patience and disappointment by its fighting powers and its beauty. Summer fishing on most rivers in the British Islands is uncertain, but in Norway summer is the season, which possibly explains to some extent the popularity of that country with British anglers, for the pleasure of a sport is largely increased by good weather.

Two methods of using the fly are in vogue, casting and harling. The first is by far the more artistic, and it may be practised either from a boat, from the bank or from the bed of the river itself; in the last case the angler wades, wearing waterproof trousers or wading-stockings and stout nail-studded brogues. In either case the fishing is similar. The fly is cast across and down stream, and has to be brought over the "lie" of the fish, swimming naturally with its head to the stream, its feathers working with tempting movement and its whole appearance suggesting some live thing dropping gradually down and across stream. Most anglers add to the motion of the fly by "working" it with short pulls from the rod-top. When a fish takes, the rise is sometimes seen, sometimes not; in any case the angler should not respond with the rod until he *feels* the pull. Then he should *tighten*, not strike. The fatal word "strike," with its too literal interpretation, has caused many a breakage. Having hooked his fish, the angler must be guided by circumstances as to what he does; the salmon will usually decide that for him. But it is a sound rule to give a well-hooked fish no unnecessary advantage and to hold on as hard as the tackle will allow. Good tackle will stand an immense

strain, and with this "a minute a pound" is a fair estimate of the time in which a fish should be landed. A foul-hooked salmon (no uncommon thing, for a fish not infrequently misses the fly and gets hooked somewhere in the body) takes much longer to land. The other method of using the fly, harling, which is practised on a few big rivers, consists in trailing the fly behind a boat rowed backwards and forwards across the stream and dropping gradually downwards. Of recent years many anglers have adopted light rods for salmon-fishing. This is, in effect, trout-fishing applied to salmon, the rod used being a single-handed one of 10ft. 6in. to 11ft. and the flies of about the same size as loch trout flies. Great success has attended this method of fishing at times of low water, when, by the older methods, it would have been considered hardly worth while trying. Dry-fly fishing for salmon on calm days, more particularly perhaps in American waters, which are more liable than British to periods of high temperature, is another innovation with salmon anglers. Fly-fishing for salmon is also practised on some lakes, into which the fish run. On lakes the boat drifts slowly along a "beat," while the angler casts diagonally over the spots where salmon are wont to lie. Salmon may also be caught by "mid-water fishing," with a natural bait either spun or trolled and with artificial spinning-baits of different kinds, and by "bottom-fishing" with prawns, shrimps and worms. Spinning is usually practised when the water is too high or too coloured for the fly; trolling is seldom employed, but is useful for exploring pools which cannot be fished by spinning or with the fly; the prawn is a valuable lure in low water and when fish are unwilling to rise; while the worm is killing at all states of the river, but except as a last resource is not much in favour. There are a few waters where salmon have the reputation of not taking a fly at all; in them spinning or prawning is the usual mode of fishing. But most anglers, wherever possible, prefer to use the fly. The rod for the alternative methods is generally shorter and stiffer than the fly-rod, though made of like material. Twelve to 14ft. represents about the range of choice. Outside the British Islands the salmon-fisher finds his headquarters in Scandinavia and Iceland, and, in the New World, in some of the waters of Canada and Newfoundland.

Landlocked Salmon.—The landlocked salmon (*Salmo salar ovananiche* and *sebag*) of Canada and the lakes of Maine is, as its name implies, now regarded by scientists as merely a landlocked form of the salmon. It does not often attain a greater size than 20 lb., but it is a fine fighter and is highly esteemed by American anglers. In most waters it does not take a fly so well as a spinning-bait, live-bait or worm. The methods of angling for it do not differ materially from those employed for other *Salmonidae*.

Pacific Salmon.—Closely allied to *Salmo salar* both in appearance and habits is the genus *Oncorhynchus*, commonly known as Pacific salmon. It contains six species, is peculiar to the North Pacific ocean, and is of some importance to the angler, though of not nearly so much as the Atlantic salmon. The quinnat is the largest member of the genus, closely resembles *salar* in appearance and surpasses it in size. The others, sockeye, humpback, coho, dog-salmon and masu, are smaller and of less interest to the angler, though some of them have great commercial value. The last-named is found only in the waters of Japan, but the rest occur in greater or less quantities in the rivers of Kamchatka, Alaska, British Columbia and Oregon. The problems presented to science by *salar* are offered by *Oncorhynchus* also, but there are variations in its life-history, such as the fact that few if any fish of the genus are supposed to survive their first spawning season. When once in the rivers none of these salmon is of very much use to the angler, as, though it is stated that they will occasionally take a fly or spoon in fresh water, they are not nearly so responsive as their Atlantic cousin and in many streams are undoubtedly not worth trying for. At the mouths of some rivers, however, where the water is distinctly tidal, and in certain bays of the sea itself they give very fine sport, the method of fishing for them being usually to trail a heavy spoon-bait behind a boat. By this means remarkable bags of fish have been made by anglers. The sport is of quite recent development.

Sea-Trout.—Next to the salmon comes the sea-trout, the other migratory salmonid of Europe. This is a fish with many local names and a good deal of local variation. Modern science, however, recognizes one "race" only, *Salmo trutta*, the sea-trout proper. The life-history of sea-trout is much the same as that of salmon, and the fish on their first return from the sea in the grilse-stage are called by many names, finnock, herling and whitling being perhaps the best known. The bull-trout, formerly considered a separate species, is now regarded as an old sea-trout which has survived many spawnings, but its exact place in salmonology is still in dispute. It is a strong fish and grows to a great size and it is a pity that it is not of greater sporting value, if only to make up for its bad reputation as an article of food. Some amends, however, are made by its cousin the sea-trout, which is one of the gamest and daintiest fish on the angler's list. It is found in most salmon rivers and also in not a few streams which are too small to harbour the bigger fish, while there are many lakes in Scotland and Ireland (where the fish is usually known as white trout) where the fishing is superb when the trout have run up into them. Fly-fishing for sea-trout is not a thing apart. A three-pounder that will impale itself on a big salmon-fly might equally well have taken a tiny trout-fly. Many anglers, when fishing a sea-trout river where they run large, 5 lb. or more, and where there is also a chance of a salmon, effect a compromise by using a light 13ft. or 14ft. double-handed rod, and tackle not so slender as to make hooking a salmon a certain disaster. But undoubtedly to get the full pleasure out of sea-trout-fishing a single-handed rod of 10ft. to 12ft. with reasonably fine gut and small flies should be used, and the way of using it is much the same as in wet-fly fishing for brown trout, which will be treated later. When the double-handed rod and small salmon-flies are used, the fishing is practically the same as salmon-fishing except that it is on a somewhat smaller scale. Flies for sea-trout are numberless and local patterns abound, as may be expected with a fish which has so catholic a taste. But, as with salmon-fishers so with sea-trout-fishers, experience forms belief and success governs selection. Among the small salmon-flies and loch-flies which will fill his book, the angler will do well to have a store of very small trout-flies at hand, while experience has shown that even the dry fly will kill sea-trout on occasion, a thing that is worth remembering where rivers are low and fish shy. July, August and September are in general the best months for sea-trout, and as they are dry months the angler often has to put up with indifferent sport. The fish will, however, rise in tidal water and in a few localities even in the sea itself, or in salt-water lochs into which streams run. Sea-trout have an irritating knack of "coming short," that is to say, they will pluck at the fly without really taking it. There are occasions, on the other hand, in loch-fishing where plenty of time must be given to the fish without tightening on it, especially if it happens to be a big one. Like salmon, sea-trout are to be caught with spinning-baits and also with the worm. The main controversy that is concerned with sea-trout is whether or not the fish captured in early spring are clean fish or well-mended kelts. On the whole, as sea-trout seldom run before May, the majority of opinion inclines to their being kelts.

Non-migratory Salmonidae.—Of the non-migratory members of the *Salmonidae* the most important in Great Britain is the brown trout (*Salmo fario*). Its American cousin the rainbow trout (*S. irideus*) is now fairly well established in Britain, too, while other trans-Atlantic species both of trout and char (which are some of them partially migratory, that is to say, migratory when occasion offers), such as the steelhead (*S. gairdneri*), fontinalis (*S. fontinalis*) and the cut-throat trout (*S. clarkii*), are at least not unknown. All these fish, together with their allied forms in America, can be captured with the fly, and speaking broadly, the wet-fly method will do well for them all. Therefore it is only necessary to deal with the methods applicable to one species, the brown trout.

Trout.—Of the game-fishes the brown trout is the most popular, for it is spread over the whole of Great Britain and most of Europe, wherever there are waters suited to it. It is a fine sporting fish and is excellent for the table, while in some streams and

lakes it grows to a very considerable size, examples of 16 lb. from southern rivers and 20 lb. from Irish and Scottish lakes being not unknown. One of the signs of its popularity is that its habits and history have produced some very animated controversies. Some of the earliest discussions were provoked by the liability of the fish to change its appearance in different surroundings and conditions, and so at one time many a district claimed its local trout as a separate species. Now, however, science admits but one species, though, to such well-defined varieties as the Loch Leven trout, the estuarine trout and the gillaroo, it concedes the right to separate names and "races." In effect all, from the great *ferox* of the big lakes of Scotland and Ireland to the little fingerling of the Devonshire brook, are one and the same—*Salmo fario*.

Wet-Fly Fishing for Trout.—Fly-fishing for trout is divided into three kinds: fishing with the artificial fly sunk or "wet," fishing with it floating or "dry" and fishing with the natural insect. Of the first two methods the wet-fly is the older and may be taken first. Time was when all good anglers cast their flies down-stream and thought no harm. But in 1857 W. C. Stewart published his *Practical Angler*, in which he taught that it paid better to fish up-stream, for by so doing the angler was not only less likely to be seen by the trout but was more likely to hook his fish. The doctrine was much discussed and criticized, but it gradually won adherents, until now up-stream fishing is the orthodox method where it is possible. Stewart was also one of the first to advocate a lighter rod in place of the heavy 12ft. and 13ft. weapons that were used in the north in his time. There are still many men who use the long rod for wet-fly fishing in streams, but there are more who find 10ft. or less enough for their purpose. For lake-fishing from a boat, however, the longer rod is still in many cases preferred. In fishing rivers the main art is to place the right flies in the right places and to let them come naturally down with the stream. The right flies may be ascertained to some extent from books and from local wisdom, but the right places can only be learnt by experience. It does not, however, take long to acquire "an eye for water" and that is half the battle, for the haunts of trout in rapid rivers are very much alike. In lake-fishing chance has a greater share in bringing about success, but here too the right fly and the right place are important; the actual management of rod, line and flies, of course, is easier, for there is no stream to be reckoned with. Though there is little left to be said about wet-fly fishing where the fly is an imitation more or less exact of a natural insect, there is another branch of the art which has been stimulated by modern developments. This is the use of salmon-flies for big trout much in the same way as for salmon. In such rivers as the Thames, where the trout are cannibals and run very large, ordinary trout-flies are of little use, and the fly-fisher's only chance is to use a big fly and "work" it, casting across and down-stream. The big fly has also been found serviceable with the great fish of New Zealand and with the inhabitants of such a piece of water as Blagdon lake, near Bristol, where the trout run very large. For this kind of fishing much stronger tackle and a heavier rod are required than for catching fish that seldom exceed the pound.

Dry-Fly.—The theory of dry-fly fishing is indeed very simple and consists in placing before the fish an exact imitation of the insect on which it is feeding, in such a way that it shall float down exactly as if it were an insect of the same kind. To this end special tackle and special methods have been found necessary. Not only the fly but also the line has to float on the water; the line is very heavy and therefore the rod (split-cane or greenheart) must be stiff and powerful; special precautions have to be taken that the fly shall float unhindered and shall not "drag"; special casts have to be made to counteract awkward winds; and, lastly, the matching of the fly with the insect on the water is a matter of much nicety, for the water-flies are of many shades and colours. Many brains have busied themselves with the solution of these problems with such success that dry-fly fishing is now a finished art. The entomology of the dry-fly stream has been studied very deeply by F. M. Halford, his friend G. S. Marryat and others, and improvements both in flies and tackle have been very great. Quite lately, however, there has been a

movement in favour of light rods for dry-fly fishing as well as wet-fly fishing. The English split-cane rod for dry-fly work weighs about an ounce to the foot, rather more or rather less. The American rod of similar action and material weighs much less—approximately 6 oz. to 10ft. The light rod, it is urged, is much less tiring and is quite powerful enough for ordinary purposes. Against it is claimed that dry-fly fishing is not “ordinary purposes,” that chalk-stream weeds are too strong and chalk-stream winds too wild for the light rod to be efficient against them. However, the light rod is growing in popular favour; British manufacturers are building rods after the American style; and anglers are taking to them more and more. The dry-fly method is now practised by many fishermen both in Germany and France, but it has only recently found a footing in the United States or Canada.

Fishing with the Natural Fly.—The natural fly is a very killing bait for trout, but its use is not wide-spread except in Ireland. In Ireland “dapping” with the green drake or the daddy-longlegs is practised from boats on most of the big loughs. A light whole-cane rod of stiff build, about 16ft. in length, is required with a floss-silk line light enough to be carried out on the breeze; the “dap” (generally two mayflies or daddy-longlegs on a small stout-wired hook) is carried out by the breeze and just allowed to touch the water. When a trout rises it is well to count “ten” before striking. Very heavy trout are caught in this manner during the mayfly season. In the north “creeper-fishing” is akin to this method, but the creeper is the larva of the stone-fly, not a fly itself, and it is cast more like an ordinary fly and allowed to sink. Sometimes, however, the mature insect is used with equally good results. A few anglers still practise the old style of dapping or “dibbling” after the manner advised by Izaak Walton. It is a deadly way of fishing small overgrown brooks. A stiff rod and strong gut are necessary, and a grasshopper or almost any large fly will serve for bait.

Other Methods.—The other methods of taking trout principally employed are spinning, live-baiting and worming. For big-river trout such as those of the Thames a gudgeon or bleak makes the best spinning or live bait, for great-lake trout (*ferox*) a small fish of their own species and for smaller trout a minnow. There are numberless artificial spinning-baits which kill well at times, the Devon being perhaps the favourite. The use of the drop-minnow, which is trolling on a lesser scale, is a killing method employed more in the north of England than elsewhere. The worm is most deadly in thick water, so deadly that it is looked on askance. But there is a highly artistic mode of fishing known as “clear-water worming.” This is most successful when rivers are low and weather hot, and it needs an expert angler to succeed in it. The worm has to be cast up-stream rather like a fly, and the method is little inferior to fly-fishing in delicacy and difficulty. The other baits for trout, or rather the other baits which they will take sometimes, are legion. Wasp-grubs, maggots, caterpillars, small frogs, bread—there is very little the fish will not take. But except in rural districts little effort is made to catch trout by means less orthodox than the fly, minnow and worm, and the tendency nowadays is to restrict anglers where possible to the use of the artificial fly only.

Grayling.—The only other member of the salmon family in England which gives much sport to the fly-fisher is the grayling, a fish which possesses the recommendation of rising well in winter. It can be caught with either wet or dry fly, and with the same tackle as trout, which generally inhabit the same stream. Grayling will take most small trout-flies, but there are many patterns of fly tied specially for them, most of them founded on the red tag or the green insect. Worms and maggots are also largely used in some waters for grayling, and there is a curious contrivance known as the “grasshopper,” which is a sort of compromise between the fly and bait. It consists of a leaded hook round the shank of which is twisted bright-coloured wool. The point is tipped with maggots, and the lure, half artificial, half natural, is dropped into deep holes and worked up and down in the water. In some places the method is very killing. The grayling has been very prominent of late years owing to the contro-

versy “grayling *versus* trout.” Many people hold that grayling injure a trout stream by devouring trout-ova and trout-food, by increasing too rapidly and in other ways. Beyond, however, proving the self-evident fact that a stream can only support a given amount of fish-life, the grayling’s opponents do not seem to have made out a very good case, for no real evidence of its injuring trout has been adduced.

Char.—The chars (*Salvelinus*) are a numerous family widely distributed over the world, but in Great Britain are not very important to the angler. One well-defined species (*Salvelinus alpinus*) is found in some lakes of Wales and Scotland, but principally in Westmorland and Cumberland. It sometimes takes a small fly but is more often caught with small artificial spinning-baits. The fish seldom exceeds 1½ lb. in Great Britain, though in Scandinavia it is caught up to 5 lb. or more. There are some important chars in America, *fontinalis* being one of the most esteemed. Some members of the genus occasionally attain a size scarcely excelled by the salmon. Among them are the Great Lake trout of America, *Cristivomer namaycush*, and the Danubian “salmon” or huchen, *Salmo hucho*. Both of these fish are caught principally with spinning-baits, but both will on occasion take a salmon-fly, though not with any freedom after they have reached a certain size. An attempt was once made to introduce huchen into the Thames, but it had no conclusive results.

Pike.—The pike (*Esox lucius*), which after the *Salmonidae* is the most valued sporting fish in Great Britain, is a fish of prey pure and simple. Though it will occasionally take a large fly, a worm or other ground-bait, its systematic capture is only essayed with small fish or artificial spinning-baits. A live-bait is supposed to be the most deadly lure for big pike, probably because it is the method employed by most anglers. But spinning is more artistic and has been found quite successful by those who give it a fair and full trial. Trolling, the method of “sink and draw” with a dead bait, referred to previously in this article, is not much practised nowadays, though at one time it was very popular. It was given up because the traditional form of trolling-tackle was such that the bait had to be swallowed by the pike before the hook would take hold, and that necessitated killing all fish caught, whether large or small. The same objection formerly applied to live-baiting with what was known as a gorge-hook. Now, however, what is called snap-tackle is almost invariably used in live-baiting, and the system is by some few anglers extended to the other method too. Pike are autumn and winter fish and are at their best in December. They grow to a very considerable size, fish of 20 lb. being regarded as “specimens” and an occasional 30-pounder rewarding the zealous and fortunate. The heaviest pike caught with a rod in recent years, which is sufficiently authenticated, is the 53 lb. specimen caught in Lake Conn, Ireland, in 1920, by John Garvin. River pike up to about 10 lb. in weight are excellent eating.

America has several species of pike, of which the muskellunge of the Great Lakes region (*Esox masquinongy*) is the most important. It is a very fine fish, excelling *Esox lucius* both in size and looks. From the angler’s point of view it may be considered simply as a large pike and may be caught by similar methods. It occasionally reaches the weight of 50 lb. or perhaps more. The pickerel (*Esox reticulatus*) is the only other of the American pikes which gives any sport. It reaches a respectable size, but is as inferior to the pike as the pike is to the muskellunge.

Perch.—Next to the pikes come the perches, also predatory fishes. The European perch (*Perca fluviatilis*) has a place by itself in the affections of anglers. When young it is easy to catch by almost any method of fishing, and a large number of Walton’s disciples have been initiated into the art with its help. Worms and small live-baits are the principal lures, but at times the fish will take small bright artificial spinning-baits well, and odd attractions such as boiled shrimps, caddis-grubs, small frogs, maggots, wasp-grubs, etc., are sometimes successful. The drop-minnow is one of the best methods of taking perch. Very occasionally, and principally in shallow pools, the fish will take an artificial fly greedily, a small salmon-fly being the best thing to use in such a case. A perch of 2 lb. is a good fish, and a specimen of 4½ lb.

about the limit of angling expectation. There have been rare instances of perch over 5 lb. and there are legends of eight-pounders, which, however, need authentication.

Black Bass.—The yellow perch of America (*Perca flavescens*) is very much like its European cousin in appearance and habits, but it is not so highly esteemed by American anglers, because they are fortunate in being possessed of a better fish in the black bass, another member of the perch family. There are two kinds of black bass (*Micropterus salmoides* and *Micropterus dolomieu*), the large-mouthed and the small-mouthed. The first is more a lake and pond fish than the second, and they are seldom found in the same waters. As the black bass is a fly-taking fish and a strong fighter, it is as valuable to the angler as a trout and is highly esteemed. Bass-flies are *sui generis*, but incline more to the nature of salmon-flies than trout-flies. An artificial frog cast with a fly-rod or very light spinning-rod is also a favourite lure. For the rest the fish will take almost anything in the nature of worms or small fish, like its cousin the perch. A 4 lb. bass is a good fish, but five-pounders are not uncommon. Black bass have to some extent been acclimatized in Italy and France, and experiments in England are in progress.

The *ruffe* or *pope* (*Acerina vulgaris*) is a little fish common in the Thames and many other slow-flowing English rivers. It is very like the perch in shape but lacks the dusky bars which distinguish the other, and is spotted with dark brown spots on a golden olive background. It is not of much use to the angler as it seldom exceeds 3 oz. in weight. It takes small worms, maggots and similar baits greedily, and is often a nuisance when the angler is expecting better fish. Allied to the perches is the pike-perch, of which two species are of some importance to the angler, one the wall-eye of eastern America (*Stizostedion vitreum*) and the other the zander of Central Europe (*Sandrus lucio-perca*). The last especially is a fine fighter, occasionally reaching a weight of 20 lb. It is usually caught by spinning, but will take live-baits, worms and other things of that nature. The Danube may be described as its headquarters. It is a fish whose sporting importance will be more realized as anglers on the Continent become more numerous.

Cyprinidae.—The carp family (*Cyprinidae*) is a large one and its members constitute the majority of English sporting fishes. In America the various kinds of chub, sucker, dace, shiner, etc., are little esteemed and are regarded as spoils for the youthful angler only, or as baits for the better fish in which the Continent is so rich. In England, however, the *Cyprinidae* have an honoured place in the affections of all who angle "at the bottom," while in Europe some of them have a commercial value as food-fishes. In India at least one member of the family, the mahseer, takes rank with the salmon as a "big game" fish.

Carp, Tench, Barbel, Bream.—The family as represented in England may be roughly divided into two groups, those which feed on the bottom purely and those which occasionally take flies. The first consists of carp, tench, barbel and bream. Of these carp, tench and bream are either river or pool fish, while the barbel is found only in rivers, principally in the Thames and Trent. The carp grows to a great size, 20 lb. being not unknown; tench are big at 5 lb.; barbel have been caught up to 14 lb. or rather more; and bream occasionally reach 8 lb., while a fish of over 11 lb. is on record. All these fish are capricious feeders, particularly carp and barbel. In some waters it seems to be impossible to catch the large specimens, and the angler who seeks to gain trophies in either branch of the sport needs both patience and perseverance. Tench and bream are not quite so difficult. The one fish can sometimes be caught in great quantities, and the other is generally to be enticed by the man who knows how to set about it. Two main principles have to be observed in attacking all these fish, ground-baiting and early rising. Ground-baiting consists in casting food into the water so as to attract the fish to a certain spot and to induce them to feed. Without it very little can be done with shy and large fish of these species. Early rising is necessary because they only feed freely, as a rule, from daybreak till about three hours after sunrise. The heat of a summer or early autumn day makes them sluggish, but an hour

or two in the evening are sometimes remunerative. The bait for them all should usually lie on the bottom, and it consists mainly of worms, wasp and other grubs, pastes of various kinds; and for carp, and sometimes bream, of vegetable baits such as small boiled potatoes, beans, peas, stewed wheat, pieces of banana, etc. None of these fish feed well in winter.

Roach, Rudd, Dace, Chub.—The next group of *Cyprinidae* consists of fish which will take a bait similar to those already mentioned and also a fly. The sizes which limit the ordinary angler's aspirations are roach about 2 lb., rudd about 2½ lb., dace about 1 lb. and chub about 5 lb. There are instances of individuals heavier than this, one or two roach and many rudd of over 3 lb. being on record, while dace have been caught up to 1 lb. 6 oz., and chub of over 7 lb. are not unknown. Roach only take a fly as a rule in very hot weather when they are near the surface, or early in the season when they are on the shallows; the others will take it freely throughout the summer. Ordinary trout flies do well enough for all four species, but chub often prefer something larger, and big bushy lures called "palmers," which represent caterpillars, are generally used for them. The fly may be used either wet or dry for all these fish, and there is little to choose between the methods as regards effectiveness. Fly-fishing for these fish is a branch of angling which might be more practised than it is, as the sport is a very fair substitute for trout-fishing. Roach, chub and dace feed on bottom food and give good sport all the winter.

Gudgeon, Bleak, Minnow, etc.—The small fry of European waters, gudgeon, bleak, minnow, loach, stickleback and bullhead, are principally of value as bait for other fish, though the latter-named species gives pretty sport on fine tackle and makes a succulent dish. Small red worms are the best bait for gudgeon and minnows, a maggot or small fly for bleak, and the rest are most easily caught in a small-meshed net. The loach is used principally in Ireland as a trout bait, and the other two are of small account as hook-baits, though sticklebacks are a valuable form of food for trout in lakes and pools.

Mahseer.—Among the carps of India, several of which give good sport, special mention must be made of the mahseer (*Barbus mosal*), a fish which rivals the salmon both in size and strength. It reaches a weight of 60 lb. and sometimes more and is fished for in much the same manner as salmon, with the difference that after about 10 lb. it takes a spinning-bait, usually a heavy spoon-bait, better than a fly.

Cat-fish.—None of the fresh-water cat-fishes (of which no example is found in England) can be described as sporting fish, but several may be caught with rod and line. There are several kinds in North America, and some of them are as heavy as 100 lb., but the most important is the wels (*Silurus glanis*) of the Danube and neighbouring waters. This is the largest European fresh-water fish, and it is credited with a weight of 300 lb. or more. It is a bottom feeder and will take a fish-bait either alive or dead; it is said occasionally to run at a spinning-bait when used very deep.

Burbot.—The burbot (*Lota vulgaris*) is the only fresh-water member of the cod family in Great Britain, and it is found only in a few slow-flowing rivers such as the Trent, and there not often, probably because it is a fish of sluggish habits which feeds only at night. It reaches a weight of 3 lb. or more, and will take most flesh or fish baits on the bottom. The burbot of America has similar characteristics.

Sturgeon.—The sturgeons, of which there are a good many species in Europe and America, cannot be taken by angling. They are anadromous fishes of which little more can be said than that a specimen might take a bottom bait once in a while. In Russia they are sometimes caught on long lines armed with baited hooks, and occasionally an angler hooks one. Such a case was reported from California in *The Field* of Aug. 19, 1905.

Shad.—Two other anadromous fish deserve notice. The first is the shad, a herring-like fish of which two species, *allice* and *twait* (*Clupea alosa* and *C. finta*), ascend one or two British and several Continental rivers in the spring. The twait is the more common, and in the Severn, Wye and Teme it sometimes gives very fair

sport to anglers, taking worm and occasionally fly or small spinning bait. It is a good fighter, and reaches a weight of about 3 lb. Its sheen when first caught is particularly beautiful. America also has its shads.

Flounder.—The other is the flounder (*Pleuronectes flesus*), the only flat-fish which ascends British rivers. It is common a long way up such rivers as the Severn, far above tidal influence, and it will take almost any flesh-bait used on the bottom. A flounder of 1 lb. is, in a river, a large one, but heavier examples are sometimes caught.

Eel.—The eel (*Anguilla vulgaris*) is regarded by the angler more as a nuisance than a sporting fish, but when of considerable size (and it often reaches a weight of 8 lb. or more) it is a splendid fighter and stronger than almost any fish that swims. Its life history has long been disputed, but it is now accepted that it breeds in the sea in the neighbourhood of the Azores and ascends rivers in its youth. It is found practically everywhere, and its occurrence in isolated ponds to which it has never been introduced by human agency has given rise to a theory that it travels overland as well as by water. The best baits for eels are worms and small fish, and the best time to use them is at night or in thundery or very wet weather.

SEA ANGLING

Sea angling is attended by almost as many refinements of tackle and method as fresh-water angling. The chief differences are differences of locality and the habits of the fish. To a certain extent sea angling may also be divided into three classes—fishing on the surface with the fly, at mid-water with spinning or other bait, and on the bottom; but the first method is only practicable at certain times and in certain places, and the others, from the great depths that often have to be sounded and the heavy weights that have to be used in searching them, necessitate shorter and stouter rods, larger reels and stronger tackle than fresh-water anglers employ. Also, of course, the sea-fisherman is liable to come into conflict with very large fish occasionally. In British waters the monster usually takes the form of a skate or halibut. A specimen of the former weighing 194 lb. has been landed off the Irish coast with rod and line in recent years. In American waters there is a much greater opportunity of catching fish of this calibre.

Great Game Fishes.—There are several giants of the sea which are regularly pursued by anglers, among them being the tarpon (*Tarpon atlanticus*) and the tuna or tunny (*Thynnus thynnus*), to which must now be added sharks, swordfish and others, particularly in Australian waters, that have already been mentioned in the section devoted to *modern conditions*. Jew-fish and black sea-bass of over 400 lb. have been taken on rod and line. Practically all of them are taken with a fish-bait either live or dead, and used stationary on the bottom or in mid-water trailed behind a boat.

British Game Fishes.—On a much smaller scale are the fishes most esteemed in British waters. The bass (*Labrax lupus*) heads the list as a plucky and rather difficult opponent. A fish of 10 lb. is a large one, but 15-pounders have been taken. Small or "school" bass up to 3 lb. or 4 lb. may sometimes be caught with the fly (generally a roughly constructed thing with big wings), and when they are really taking, the sport is magnificent. In some few localities it is possible to cast for them from rocks with a salmon rod, but usually a boat is required. In other places bass may be caught from the shore with fish-bait used on the bottom in quite shallow water. They may again sometimes be caught in mid-water, and in fact there are few methods and few lures employed in sea angling which will not account for them at times. The pollack (*Gadus pollachius*) and coal-fish (*Gadus virens*) come next in esteem. Both in some places reach a weight of 20 lb. or more, and both when young will take a fly. Usually, however, the best sport is obtained by trailing some spinning-bait, such as an artificial or natural sand-eel, behind a boat. Sometimes, and especially for pollack, the bait must be kept near the bottom and heavy weights on the line are necessary; the coal-fish are more prone to come to the surface for feeding. The larger grey mullet (*Mugil capito*) is a great favourite with many anglers, as it is

extremely difficult to hook, and when hooked fights strongly. Fishing for mullet is more akin to fresh-water fishing than any branch of sea-angling, and indeed can be carried on in almost fresh water, for the fish frequent harbours, estuaries and tidal pools. They can be caught close to the surface, at mid-water and at the bottom, and as a rule vegetable baits, such as boiled macaroni, or rag-worms are found to answer best. Usually ground-baiting is necessary, and the finer the tackle used the greater is the chance of sport. Not a few anglers fish with a float as if for river fish. The fish runs up to about 8 lb. in weight. The cod (*Gadus morhua*) grows larger and fights less gamely than any of the fish already mentioned. It is generally caught with bait used on the bottom from a boat, but in places codling, or young cod, give some sport to anglers fishing from the shore. The mackerel (*Scomber scomber*) gives the best sport to a bait, usually a strip of fish skin, trailed behind a boat fairly close to the surface, but it will sometimes feed on the bottom. Mackerel on light tackle are game fighters, though they do not usually much exceed 2 lb. Whiting and whiting-pout (*Gadus merlangus* and *G. luscus*) both feed on or near the bottom, do not grow to any great size, and are best sought with fine tackle, usually an arrangement of three or four hooks at intervals above a lead which is called a "paternoster." If one or more of the hooks are on the bottom the tackle will do for different kinds of flat fish as well, flounders and dabs being the two species most often caught by anglers. The bream (*Pagellus centrodontus*) is another bottom-feeder which resembles the fresh-water bream both in appearance and habits. It is an early morning or rather a nocturnal fish, and grows to a weight of 3 lb. or 4 lb. Occasionally it will feed in mid-water or even close to the surface. The conger eel (*Conger vulgaris*) is another night-feeder, which gives fine sport, as it grows to a great size and is very powerful. Strong tackle is essential for conger fishing, as so powerful an opponent in the darkness cannot be given any law. The bait must be on or near the bottom. There are, of course, many other fish which come to the angler's rod at times, but the list given is fairly complete as representing the species which are especially sought. Beside them are occasional (in some waters too frequent) captures such as dog-fish and sharks, skates and rays. Many of them run to a great size and give plenty of sport on a rod, though they are not as a rule welcomed. Lastly, it must be mentioned that certain of the *Salmonidae*, smelts (*Osmerus eperlanus*), sea-trout, occasionally brown trout, and still more occasionally salmon can be caught in salt water either in sea-lochs or at the mouths of rivers. Smelts are best fished for with tiny hooks tied on fine gut and baited with fragments of shrimp, rag-worm and other delicacies.

Legislation.—A Fishery Act for England and Wales, passed in 1923, improves and consolidates previous legislation. The pollution of rivers has inspired a new movement of co-operation between industrial and fishing interests. The British government set up a pollution committee, which has been at work for several years, and from its labours some good results are apparent. A deputation to the prime minister organized by the joint efforts of the Salmon and Trout Association and the British Waterworks Association in Feb. 1927, urging the appointment of a central water authority, has resulted in the setting up of two new committees, one for technical research into ways and means of abating pollution, the other to act in an advisory capacity to the government on legislative and administrative questions in regard to rivers. A new source of danger is the dressing of roads made necessary by increased motor traffic. It has been established that tar, very largely used at first, may have disastrous effects when road washings get into streams. The trouble is in some cases being removed by the use of bitumen instead, and experiment is being carried on by the pollution committee in regard to other safeguards.

(H. T. S.; H. D. T.)

UNITED STATES

Sea angling in the United States has enrolled more new members since 1918 than any other sport. This is largely due to cheap and rapid transportation. Where in the days of the old sail boats it would take five or six hours to reach a spot off shore, the same run is now made in an hour or so with a cer-

tainty of getting back within a specified time. In 1918 there were perhaps five or six open deep-sea fishing boats leaving from New York or nearby ports. Ten years later there was a fleet of over 200. Inland anglers, tired of catching smaller species of fresh-water fish, go from Cincinnati, Pittsburgh or other inland cities to try their luck for the big fish along the shores of Virginia, North Carolina and Florida, or to the west coast for tuna or broadbill swordfish.

Big-fish angling has advanced more than any other branch of angling. Big-fish hunters on both the Atlantic and Pacific coasts have caught with rod and reel tuna weighing up to 758 lb. and broadbill swordfish of more than 500 lb. In 1926, in the waters of New Zealand, an American with rod and reel landed a black marlin swordfish that tipped the scale at 976 lb. It seems almost impossible to believe that human ingenuity has made rods, reels and lines capable of landing fish of such great size. There are many sea anglers who catch their fish on the lightest possible tackle, and valuable prizes are offered for landing huge game fish with this tackle. In fact, one club in America permits its members to use only cotton thread, and striped bass, weakfish or bluefish over 10 lb., handled on this thread, take considerable time and skill to land.

The tackle used for sea angling consists of a rod made of six strips of bamboo glued together, or hickory, bathabara, greenheart, black palm, lancewood or palma brava woods. To these rods are attached guides, preferably of agate. At the end of the rod is a butt upon which is affixed a reel seat, made of German silver, to which the reel is fastened. Butts are made of hickory or other wood, and wound with either cane or cork. Only lines of linen should be used and great care should be exercised when drying them as rust spots will prove disastrous. The hooks, sinkers and various lures differ according to the species of fish sought. There are hundreds of species of salt-water fish which abound on the east and west coasts of the United States. In fact in the salt waters bordering on Florida there are more than 600 species, but there will be discussed here only those that are most sought after for their gameness and flesh by the followers of Izaak Walton.

Flounders, Fluke and Halibut.—Flounders are caught on the east coast from Maine to Virginia and usually come out of their mud beds about February. They are found in bays or inlets where there is a sandy bottom. A light rod is employed in their capture, the tip of which should weigh 3 or 4 oz. A nine or ten Chestertown hook, six thread linen line and a sinker just heavy enough to hold bottom in the tide should be used. The hooks should be tied closely to the sinker as the flounder is a bottom feeder, and sand, blood or earth worms should be used as a lure. As the flounder has an exceedingly small mouth and has a habit of sucking in the bait, do not try to strike him at the first nibble, but allow plenty of time for the bait and hook to pass into the mouth before sinking the hook. Flounders weigh from $\frac{1}{2}$ lb. to 4 lb. each, with an occasional specimen of 6 lb. Net fishermen have brought them in weighing over 10 lb. each.

The fluke is of the flat species, belonging to the flounder family, but is larger in size and has a fairly big mouth with teeth. He is found in the oceans, inlets and bays, usually along sandy, clean bottoms. A rod with a tip weighing 5 oz. to 6 oz. is used and a linen line of six to nine thread, affixed to which is a gut leader about 3 ft. long. A number 4 to 10 Kirby hook is the right size. Killies spearing or cut-fish bait is used principally as lures. The fluke may be taken at any time during the day regardless of tides. The best method of capture is to allow the boat to drift over the grounds where fluke have their habitat, allowing bait to drag on the bottom. Fluke weigh from 1 lb. to 16 lb.; occasionally one is brought in by the beam trawlers weighing from 20 to 25 lb.

Halibut are rarely sought by anglers owing to the fact that their habitat is so far off shore that it is difficult to reach them. They are usually taken at the banks off Newfoundland and off the coast of California, Oregon and Washington. The largest halibut ever known to be caught was landed off the Grand Banks about 1918 and weighed 680 lb.

Striped Bass, Seabass, Porgies and Blackfish.—The striped bass is a much sought after salt-water fish, and ranges from Maine to the Carolinas. In 1886, 300 of them were taken from the

Shrewsbury river of New Jersey and planted in the waters of California. They have flourished on the west coast because of the strictly enforced laws in California protecting them. They can be taken from April to November and are found in the ocean close to shore, in bays and rivers of brackish water. The rod should weigh from 3 oz. to 10 oz. and the line should be of linen from 6 to 15 thread. A 4 to 10-O Sproat hook affixed to gut is used when bait fishing, and crabs, clams, worms, eels, mullet and cut-up fish are used as lures. They will also strike a lead squid or spoon. They are caught at any time of day or night and on almost any tide. Striped bass weigh from 1 lb. to 73 lb.—the world's record by angling. But specimens have been taken in the nets weighing over 100 lb.

Seabass range from Long Island to the Carolinas. They resemble, somewhat, fresh-water bass, and come in huge schools, having their habitat around rocks or wrecks. A 5 oz. or 6 oz. rod is used in their capture, and the line should be of from 9 to 12 thread. They feed on sea clams, squid (inkfish) and mossbunker. A 3 to 5-O Sproat or O'Shaughnessy hook should be used and a sinker heavy enough to hold bottom. As a rule when a seabass hits the lure he hooks himself and gives a fair account of himself, considering his size. Seabass weigh from $\frac{1}{2}$ lb. to 7 lb., and are eagerly sought after by the deep-sea anglers of New Jersey and Long Island.

Porgies usually make their appearance with the seabass and are caught on the same tackle. The blackfish or tautog is caught over rocks and wrecks in the oceans and bays from Maine to the Carolinas. A number 1 to 6 Virginia hook is employed and the same tackle used as prescribed for seabass. Blackfish feed on clams, crabs and worms. The larger fish, being suspicious, are hard to hook, but they usually give warning before they take hold, and it is advisable to allow a blackfish plenty of time to let the bait pass well into his jaws before setting the hook.

Cod, Pollock, Hake and Ling.—These species are caught along the Atlantic coast from Newfoundland to Virginia and also along the west coast. A rod weighing from 6 oz. to 10 oz. is used and the line should be from 12 to 15 thread. The hooks can be either 6-O to 9-O Sproat or O'Shaughnessy, and clams, conchs, scallop guts or cut-fish bait are used as lure. These species are caught during the spring and winter. At times they come fairly close to shore, but are usually taken from 1m. to 12m. from the shore line, in water anywhere from 60ft. to 90ft. deep. They can hardly be termed game fish. The cod usually captured by angling weighs from 3 to 60 lb. These four species travel together and often on one ground all four may be taken on the same day.

Bluefish and Weakfish.—These two species are eagerly sought by anglers from Massachusetts south to Florida. They are both game, hard fighting fish with the bluefish the harder fighter of the two. In fact, the bluefish is classed by many as being the gamest fish for his weight and size that swims the Seven Seas. He is a veritable bulldog at the end of a swaying rod and knows every trick of getting away. Tackle employed for the capture of weakfish and bluefish consists of a rod weighing from 3 to 6 oz. The line should be of linen from 6 to 12 thread. A 3-O to 7-O Sproat or O'Shaughnessy hook is best. Bluefish are usually caught by trolling with a lead spoon or squid or by grinding up moss bunker and throwing it overboard thus causing what is known as a slick which runs from the boat out across the water with the tide bringing the bluefish close to the boat. A piece of bunker bait is affixed to the hook, which is attached to 4ft. or 5ft. of German silver wire. This is thrown overboard and allowed to drift out in the chum line.

Weakfish are chummed to the boat using small shrimp or mossbunker and as a bait for weakfish, crabs, cut-fish, large sand or blood worms, squid (inkfish) or shrimp are used. These fish can be taken during the day or night and bite on the first of the flood and the last of the ebb tides. Weakfish range in weight from 1 lb. to 16 lb. and some which weighed over 20 lb. have been taken in the nets by professional fishermen. The bluefish range in weight about the same as weakfish, and a 10 or 12 pounder of either of these species is a prize worth angling for.

Channel Bass and Drum.—Channel bass or red drum is dis-

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY ISABEL COOPER, AFTER A SPECIMEN IN THE AMERICAN MUSEUM OF NATURAL HISTORY

THE SAILFISH A SPECIES OF SWORDFISH MUCH SOUGHT BY DEEP-SEA ANGLERS

The sailfish has a long, high back fin, which is often raised above the surface of the water. The Pacific ocean species, found in the waters around Lower California, grows 6 to 10 feet in length and weighs 50 to 150 pounds. The Atlantic ocean species is found in the waters around Florida.

tinguishable from the ordinary drum by a black spot near its tail. It is shaped somewhat like striped bass and is a fine fighter. It may be caught from New Jersey south to Florida, and is found feeding close to shore along the surf, in inlets and bays. A rod weighing from 10 oz. to 12 oz., a linen line, 6 to 15 thread, and 3-O Ring Virginia hooks, affixed to German silver wire 2ft. long should be used. The best lures for these fish are menhaden, crabs and mullet. They are caught from May to October during the day or night; nightfall is the best, on the flood tide. Channel bass weigh from 5 lb. to 65 lb. Drum fish are often caught weighing 70 lb. and 80 lb., but do not give one the battle that the channel bass does.

Tuna, Albacore and Bonita.—These three species are similar in shape, but differ in their markings and size. The bonita is the smallest with the albacore next in size. They are usually found feeding on the same grounds and all three are swift swimmers and hard fighters. Heavy tackle is employed because one usually is seeking tuna. The tackle is so strong that little difficulty is experienced in reeling in a bonita of 6 lb. or an albacore of 20 lb., when one is after tuna weighing 200 lb. or 300 lb. These three species are usually caught while trolling and various artificial lures are affixed to a 9ft. German silver wire leader. The rod is extremely heavy, weighing in the neighbourhood of 16 oz. The reel is a huge affair, weighing 7 or 8 lb., and is capable of holding 900ft. to 1200ft. of number 36 thread line. These fish range along the Atlantic coast from Canada to Florida and also in the Pacific ocean, off California. They are taken from daylight to sunset.

When one is fishing from an anchored boat, cut-fish bait is used as a lure. Tuna range in weight from 30 lb. to 1500 lb. The largest ever taken by angling weighed 758 lb. They are rarely caught off the Long Island or New Jersey coasts weighing more than 100 lb.; but in the Pacific ocean, many weighing well over this weight have been captured. The tuna is one of the most powerful fish that swims and a big specimen will give an angler a tussle long to be remembered. They never jump clear of the water and have a tendency after being hooked to go down to the bottom and must be "pumped" up.

Broadbill and Marlin Swordfish.—Within recent years these two species have claimed many devotees, who concentrate their efforts around Catalina island, Calif., where hundreds of both of these species have been taken. The same tackle that is employed for tuna is used for swordfish, only a whole fish of two or three pounds is used as the lure, or a large portion of cut-fish. They are difficult to entice to take the bait and are hard to hook once they have struck it with their bill. When one is hooked, since the jaws are soft, when the fish leaps clear of the water the hook is often thrown from the fish's mouth. The most experienced broadbill swordfisherman tries to snag the fish anywhere in the body but the mouth.

The first broadbill swordfish taken by angling off the Atlantic seaboard was landed off Montauk, L.I., in 1927. This fish weighed 193 lb. Expert broadbill swordfishermen claim this species to be more prolific off Block island, R.I., and Montauk, L. I., than at the famous waters around Catalina island, and the capture of this fish should open up a new swordfishing resort in the east. Swordfish rarely weigh under 100 lb., and go to 500 lb. or 600 lb., with the world's record for any fish caught by rod and reel being held by a black marlin 976 lb. swordfish taken in 1926 off New Zealand.

Tarpon.—Tarpon or silver king, is the most advertised fish in the world. It is caught on the east and west coasts of Florida, in

the Gulf of Mexico and off Panama. It is a huge herring and when hooked leaps many feet into the air. The rods used for its capture weigh 6 oz., 8 oz. and 12 oz. The line should be of linen 9 to 24 thread, and hooks 8-O to 10-O O'Shaughnessy. The tarpon are found in bays and inlets and the best time to seek them is on moonlight nights during the flood tide. They may be caught from February to June, May and June being the best months. One uses a spoon while trolling, and when still fishing, mullet or cut-fish. Tarpon weigh anywhere from 10 lb. to 200 lb. with the average fish weighing about 100 lb. They are practically useless as food, and many anglers after catching them allow them their freedom.

Sailfish.—The sailfish resembles the swordfish. It derives its name from the huge dorsal fin that extends a foot or two above the body, resembling a sail. They also clear the water by many feet when hooked, and are eagerly sought in the waters off Florida and off southern California. About the same tackle is employed as in the capture of the tarpon. Five to 8-O tandem hooks, baited with cut-fish, usually are most effective. The sailfish is a surface feeder and is caught by trolling in the daytime. Sailfish weigh from 30 lb. to 100 lb., a new world's record being established in 1927 with a sailfish caught off Panama measuring 10½ft. in length, and weighing 177 lb. They are an exceedingly difficult fish to hook owing to their unreadiness to take the lure into their mouths. Hooking a sailfish is an art that some anglers cannot master even after repeated trials.

Bonefish.—Veteran anglers claim the bonefish to be one of the gamest fish that swims. They are the colour of mother of pearl, are long and have a streamlike body, with tail and fins of large proportions which send them through the water with lightning speed. They are found in shallow water in Florida and the Bimini islands. The rod universally used weighs 6 oz.; the line is of linen, 9 thread; the hook is 1 to 1-O Sproat. Hermit crab is the best lure. They are taken from February to June at almost any time of day. They are exceedingly shy and are usually sighted in the 18in. to 24in. of water in which they swim by their tails sticking out of the water when they are rooting for food at the bottom. Bonefish weigh from 3 lb. to 10 lb. When fishing in southern waters on either the east or west coast along with the tarpon and sailfish, one catches barracuda, amberjack, yellow tail, king mackerel and a host of other species, all of which are caught on the same tackle as is used for tarpon or sailfishing. The same lures are likewise effective with these species. (F. Fl.)

Carter Platts, *Trout Streams, their Management and Improvement* (1927).

Geographical Literature.—For the British Isles the fine series of books produced by Augustus Grimbly, *The Salmon Rivers of Scotland, Salmon Rivers of England and Wales, and Salmon Rivers of Ireland* (1900-04) are still of value, though conditions have changed since they appeared. *The Salmon Rivers and Lochs of Scotland*, by W. L. Calderwood (new ed. 1921) is also worthy of special note. *Where to Fish: The Angler's Diary* (published periodically) gives a long list of books of geographical importance for various parts of the world, besides catalogues of fishing literature published in recent years and a record of later history and developments. There are now many local guidebooks published by railways, steamship companies and other bodies interested in publicity work.

Fishery Law.—*Oke's Fishery Laws*, edited by Hubert Hull (1924, latest ed.), a revision made necessary by the new Act of 1923.

ANGLO-ISRAELITE THEORY, the contention, historically and etymologically unsound, that the English-speaking peoples are the descendants of the "ten tribes" of Israel, deported by Sargon of Assyria on the fall of Samaria in 721 B.C. The theory, still held by over 2,000,000 people, materially assisted the resettlement of Jews in England in the 17th century. Richard Brothers (1757-1824), the "Nephew of the Almighty," may be regarded as its first modern apostle.

BIBLIOGRAPHY.—For influence on resettlement see A. M. Hyamson, *Jewish Quarterly Review*, pp. 640 seq. (July 1903). GENERAL: full accounts and bibliographies s.v. *Anglo-Israelism* in *Jewish Encyclopedia* and in Hastings' *E.R.E.*

ANGLO-JAPANESE ALLIANCE. On Jan. 30 1902, owing to the threat of Russian aggression in the Far East, Great Britain and Japan concluded an alliance of a defensive character which provided for mutual assistance in the safeguarding of British interests in China and Japanese interests in China and Korea. The agreement was a valuable asset to Japan in the war with Russia which broke out in 1904; but it did not involve Great Britain in active hostilities.

In 1905 the agreement was revised; its scope was extended to India and Eastern Asia generally, and Japan's paramount position in Korea was more definitely emphasized. Later developments, notably the annexation of Korea to the Japanese Empire in 1910, led to the renewal of the alliance on July 13, 1911. An important feature of the new agreement was the inclusion of an article exempting either high contracting party from the obligation to come to the armed assistance of the other in case of war against a Power with whom either party had concluded a general arbitration treaty (Article 4). The alliance of 1911 was to last for ten years, but in the absence of a year's notice from either contracting party to terminate the agreement it would automatically continue in existence, even after July 1921.

Abrogation of the Alliance.—In consequence of the Anglo-Japanese alliance Japan entered readily into the World War on Aug. 23 1914; but the Treaty of Versailles brought forth the League of Nations, and apart from doubts whether the alliance was not inconsistent with the obligations of the Covenant of the League, both Great Britain and Japan were becoming aware that it was increasingly unpopular in the United States and in China. At the Washington Conference (q.v.), therefore, in Dec. 1921, the agreement made for a Four-Power Pacific treaty (United States, France, British Empire, Japan) provided for the conclu-

sion of the Anglo-Japanese alliance. The alliance, therefore, ceased to exist on the deposition of the ratifications of the above treaty on Aug. 17 1923. For 21 years it had been the most stable influence in the Far Eastern position, and a cardinal factor in British and Japanese policy. (See JAPAN: History.)

ANGLO-NORMAN LITERATURE. The French language (q.v.) came over to England with William the Conqueror. During the whole of the 12th century it shared with Latin the distinction of being the literary language of England, and it was in use at the court until the 14th century. It was not until the reign of Henry IV. that English became the native tongue of the kings of England. After the loss of the French provinces, schools for the teaching of French were established in England, among the most celebrated of which we may quote that of Marlborough. The language then underwent certain changes which gradually distinguished it from the French spoken in France; but, except for some graphical characteristics, from which certain rules of pronunciation are to be inferred, the changes to which the language was subjected were the individual modifications of the various authors, so that, while we may still speak of Anglo-Norman writers, an Anglo-Norman language, properly so called, gradually ceased to exist. The prestige enjoyed by the French language, which, in the 14th century, the author of the *Manière de langage* calls "le plus bel et le plus gracieux langage et plus noble parler, après latin d'escole, qui soit au monde et de touz genz mieulx prisée et amée que nul autre (quar Dieux le fist si douce et amiable principalement à l'onneur et loenge de luy mesmes. Et pour ce il peut comparer au parler des angels du ciel, pour la grand douceur et biaultée d'icel)," was such that it was not till 1363 that the chancellor opened the parliamentary session with an English speech. And, although the Hundred Years' War led to a decline in the study of French and the disappearance of Anglo-Norman literature, the French language continued, through some vicissitudes, to be the classical language of the courts of justice until the 17th century. It is still the language of the Channel islands, though there too it tends more and more to give way before the advance of English.

It will be seen from the above that the most flourishing period of Anglo-Norman literature was from the beginning of the 12th century to the end of the first quarter of the 13th. The end of this period is generally said to coincide with the loss of the French provinces to Philip Augustus, but literary and political history do not correspond quite so precisely, and the end of the first period would be more accurately denoted by the appearance of the history of William the Marshal in 1225 (published for the *Société de l'histoire de France*, by Paul Meyer, 3 vols., 1891-1901). It owes its brilliancy largely to the protection accorded by Henry II. of England to the men of letters of his day. "He could speak French and Latin well, and is said to have known something of every tongue between 'the Bay of Biscay and the Jordan.' He was probably the most highly educated sovereign of his day, and amid all his busy active life he never lost his interest in literature and intellectual discussion; his hands were never empty, they always had either a bow or a book" (*Dict. of Nat. Biog.*). Wace and Benoît de Sainte-More compiled their histories at his bidding, and it was in his reign that Marie de France composed her poems. An event with which he was closely connected, viz., the murder of Thomas Becket, gave rise to a whole series of writings, some of which are purely Anglo-Norman. In his time appeared the works of Beroul and Thomas respectively, as well as some of the most celebrated of the Anglo-Norman *romans d'aventure*. It is important to keep this fact in mind when studying the different works which Anglo-Norman literature has left us.

Epic and Romance.—The French epic came over to England at an early date. We know that a *Chanson de Roland* was sung

at the battle of Hastings, and we possess Anglo-Norman mss. of a few *chansons de geste*. The *Pèlerinage de Charlemagne* (Koschwitz, *Altfranzösische Bibliothek*, 1883) was, for instance, only preserved in an Anglo-Norman manuscript of the British Museum (now lost), although the author was certainly a Parisian. The oldest manuscript of the *Chanson de Roland* that we possess is also a manuscript written in England, and amongst the others of less importance we may mention *La Chançon de Willame*, the ms. of which has (June 1903) been published in facsimile at Chiswick (cf. Suchier's edition in *Bibliotheca Normannica*. T. viii. [1911] and Elizabeth Hearn Tyler [Oxford Univ. Press, 1916]). Although the diffusion of epic poetry in England did not actually inspire any new *chansons de geste*, it developed the taste for this class of literature, and the epic style in which the tales of *Horn*, of *Bovon de Hampton*, of *Guy of Warwick* (still unpublished), of *Waldef* (still unpublished) and of *Fulk Fitz Warine* are treated, is certainly partly due to this circumstance. Although the last of these works has come down to us only in a prose version, it contains unmistakable signs of a previous poetic form, and what we possess is really only a rendering into prose similar to the transformations undergone by many of the *chansons de geste* (cf. L. Brandin, *Fouke Fitz Warin* [1928]).

The interinfluence of French and English literature can be studied in the Breton romances and the *romans d'aventure* even better than in the epic poetry of the period. The *Lay of Orpheus* is known to us only through an English imitation; the *Lai du cor* was composed by Robert Biket, an Anglo-Norman poet of the 12th century (Wulff, Lund, 1888). The *lais* of Marie de France were written in England, and the greater number of the romances composing the *matière de Bretagne* seems to have passed from England to France through the medium of Anglo-Norman. The legends of Merlin and Arthur, collected in the *Historia Regum Britanniae* by Geoffrey of Monmouth (d. 1154), passed into French literature bearing the character which the bishop of St. Asaph had stamped upon them. Chrétien de Troyes' *Perceval* (c. 1175) is doubtless based on an Anglo-Norman poem. Robert de Boron (c. 1215) took the subject of his *Merlin* (published by G. Paris and J. Ulrich, 1886, 2 vols., *Société des Anciens Textes*) from Geoffrey of Monmouth. Finally, the most celebrated love-legend of the middle ages, and one of the most beautiful inventions of world-literature, the story of Tristan and Iseult, tempted two authors, Beroul and Thomas, the first of whom is probably, and the second certainly, Anglo-Norman (see ARTHURIAN LEGEND; GRAIL, THE HOLY; TRISTAN). One *Folie-Tristan* was composed in England in the last years of the 12th century. (For all these questions see *Soc. des Anc. Textes*, Muret's ed. 1903; Bédier's ed. 1902-05.) Less fascinating than the story of Tristan and Iseult, but nevertheless of considerable interest, are the two *romans d'aventure* of Hugh of Rutland, *Ipomedon* (published by Kölbing and Koschwitz, Breslau, 1889) and *Protesilaus* (still unpublished), written about 1185. The first relates the adventures of a knight who married the young duchess of Calabria, niece of King Meleager of Sicily, but was loved by Medea, the king's wife. The second poem is the sequel to *Ipomedon*, and deals with the wars and subsequent reconciliation between Ipomedon's sons, Daunus, the elder, lord of Apulia, and Protesilaus, the younger, lord of Calabria. Protesilaus defeats Daunus, who had expelled him from Calabria. He saves his brother's life, is reinvested with the dukedom of Calabria and, after the death of Daunus, succeeds to Apulia. He subsequently marries Medea, King Meleager's widow, who had helped him to seize Apulia, having transferred her affection for Ipomedon to his younger son (cf. Ward, *Cat. of Rom.*, i. 728). To these two romances by an Anglo-Norman author, *Amadas et Idoine*, of which we possess only a Continental version, is to be added. Gaston Paris has proved indeed that the original was composed in England in the 12th century (*An English Miscellany presented to Dr. Furnivall in Honour of his Seventy-fifth Birthday*, 1901, 386-394). The Anglo-Norman poem on the *Life of Richard Coeur de Lion* is lost, and an English version only has been preserved. About 1250 Eustace of Kent introduced into England the *roman d'Alexandre* in his *Roman de toute chevalerie*, many passages of which have been imitated in one of the oldest

English poems on Alexander, namely, *King Alisaunder* (P. Meyer, *Alexandre le grand*, 1886, ii. 273, and Weber, *Metrical Romances*, Edinburgh).

Fabliaux, Fables and Religious Tales.—In spite of the incontestable popularity enjoyed by this class of literature, we have only seven *fabliaux* written in England. As to fables, one of the most popular collections in the middle ages was that written by Marie de France, which she claimed to have translated from *King Alfred*. In the *Contes moralisés*, written by Nicole Bozon shortly before 1320 (*Soc. Anc. Textes*, 1889), a few fables bear a strong resemblance to those of Marie de France.

The religious tales deal mostly with the Mary Legends, and have been handed down to us in three collections:

(i.) The Adgar's collection. Most of these were translated from William of Malmesbury (d. 1143?) by Adgar in the 12th century ("Adgar's Marien-Legenden," *Altfr. Biblioth.* ix.; J. A. Herbert, *Rom.* xxxii. 394).

(ii.) The collection of Everard of Gateley, a monk of St. Edmund at Bury, who wrote c. 1250 three Mary Legends (*Rom.* xxix. 27).

(iii.) An anonymous collection of 60 Mary Legends composed c. 1250 (Brit. Museum Old Roy. 20 B, xiv.), some of which have been published in Suchier's *Bibliotheca Normannica*; in the *Altfr. Bibl.* See also Mussafia, "Studien zu den mittelalterlichen Marienlegenden" in *Sitzungsber. der Wien. Akademie* (t. cxiii., cxv., cxix., cxxiii., cxxix.).

Another set of religious and moralizing tales is to be found in Chardri's *Set dormans* and *Josaphat*, c. 1216 (Koch, *Altfr. Bibl.*, 1880; G. Paris, *Poèmes et légendes du moyen âge*).

History.—Of far greater importance, however, are the works which constitute Anglo-Norman historiography. The first Anglo-Norman historiographer is Geoffrey Gaimar, who wrote his *Estorie des Angles* (between 1147 and 1151) for Dame Constance, wife of Robert Fitz-Gislebert (*The Anglo-Norman Metrical Chronicle*, Hardy and Martin, i. ii., 1888). This history comprised a first part (now lost), which was merely a translation of Geoffrey of Monmouth's *Historia Regum Britanniae*, preceded by a history of the Trojan War, and a second part which carries us as far as the death of William Rufus. For this second part he has consulted historical documents, but he stops at the year 1087, just when he has reached the period about which he might have been able to give us some first-hand information. Similarly, Wace in his *Roman de Rou et des ducs de Normandie* (edit. Andresen, Heilbronn, 1877-79, 2 vols.), written 1160-74, stops at the battle of Tinchebray in 1107 just before the period for which he would have been so useful. His *Brut* or *Geste des Bretons* (Le Roux de Lincy, 1836-38, 2 vols.), written in 1155, is merely a translation of Geoffrey of Monmouth. "Wace," says Gaston Paris, speaking of the *Roman de Rou*, "traduit en les abrégant des historiens latins que nous possédons; mais ça et là il ajoute soit des contes populaires, par exemple sur Richard I^{er}, sur Robert I^{er}, soit des particularités qu'il savait par tradition (sur ce même Robert le magnifique, sur l'expédition de Guillaume, etc.) et qui donnent à son oeuvre un réel intérêt historique. Sa langue est excellente; son style clair, serré, simple, d'ordinaire assez monotone, vous plaît par sa saveur archaïque et quelquefois par une certaine grâce et une certaine malice."

The History of the Dukes of Normandy by Benoît de Sainte-More is based on the work of Wace. It was composed at the request of Henry II. about 1170, and takes us as far as the year 1135 (edit. by Francisque Michel, 1836-44, *Collection de documents inédits*, 3 vols.). The 43,000 lines which it contains are of but little interest to the historian; they are too evidently the work of a *romancier courtois*, who takes pleasure in recounting love-adventures such as those he has described in his romance of Troy. Other works, however, give us more trustworthy information, for example, the anonymous poem on Henry II.'s *Conquest of Ireland* in 1172 (edit. Francisque Michel, 1837), which, together with the *Expugnatio hibernica* of Giraud de Barri, constitutes our chief authority on this subject. The *Conquest of Ireland* was republished in 1892 by Goddard Henry Orpen, under the title of *The Song of Dermot and the Earl*. Similarly, Jourdain Fan-

tosme, who was in the north of England in 1174, wrote an account of the wars between Henry II., his sons, William the Lion of Scotland and Louis VII., in 1173 and 1174 (*Chronicle of the reigns of Stephen . . . III.*, edit. by Joseph Stevenson and Fr. Michel, 1886, pp. 202-307). Not one of these histories, however, is to be compared in value with *The History of William the Marshal, Count of Striguil and Pembroke*, regent of England from 1216-19, found and subsequently edited by Paul Meyer for the Société de l'histoire de France (3 vols., 1891-1901). This masterpiece of historiography was composed in 1225 or 1226 by a professional poet of talent at the request of William, son of the marshal. It was compiled from the notes of the marshal's squire, John d'Early (d. 1230 or 1231), who shared all the vicissitudes of his master's life and was one of the executors of his will. This work is of great value for the history of the period 1186-1219, as the information furnished by John d'Early is either personal or obtained at first hand. In the part which deals with the period before 1186, it is true, there are various mistakes, due to the author's ignorance of contemporary history, but these slight blemishes are amply atoned for by the literary value of the work. The style is concise, the anecdotes are well told, the descriptions short and picturesque; the whole constitutes one of the most living pictures of mediaeval society. Very pale by the side of this work appear the *Chronique* of Peter of Langtoft, written between 1311 and 1320, and mainly of interest for the period 1294-1307 (edit. by T. Wright, 1866-68); the *Chronique* of Nicholas Trevet (1258?-1328?), dedicated to Princess Mary, daughter of Edward I. (Dufus Hardy, *Descr. Catal.* III., 349-350); the *Scala Chronica* compiled by Thomas Gray of Heaton (died c. 1369), which carries us to the year 1362-63 (edit. by J. Stevenson, Maitland Club, Edinburgh, 1836); the *Black Prince*, a poem by the poet Chandos, composed about 1386, and relating the life of the Black Prince from 1346-76 (re-edited by Francisque Michel, 1883); and, lastly, the different versions of the *Brutes*, the form and historical importance of which have been indicated by Paul Meyer (*Bulletin de la Société des Anciens Textes*, 1878, pp. 104-145), and by F. W. D. Brie (*Geschichte und Quellen der mittellenglischen Prosa-chronik*, *The Brute of England or The Chronicles of England*, Marburg, 1905).

Finally we may mention, as ancient history, the translation of Eutropius and Dares, by Geoffrey of Waterford (13th century), who gave also the *Secret des Secrets*, a translation from a work wrongly attributed to Aristotle (*Rom.* xxiii. 314).

Satire and Drama.—The popularity enjoyed by the *Roman de Renart* and the Anglo-Norman version of the *Riote du Monde* (*Z. f. rom. Phil.* viii. 275-289) in England is proof enough that the French spirit of satire was keenly appreciated. The clergy and the fair sex presented the most attractive target for the shots of the satirists. However, an Englishman raised his voice in favour of the ladies in a poem entitled *La Bonté des dames* (Meyer, *Rom.* xv. 315-339), and Nicole Bozon, after having represented "Pride" as a feminine being whom he supposes to be the daughter of Lucifer, and after having fiercely attacked the women of his day in the *Char d'Orgueil* (*Rom.* xiii. 516), also composed a *Bounté des femmes* (P. Meyer, *op. cit.* 33) in which he covers them with praise, commending their courtesy, their humility, their openness and the care with which they bring up their children. A few pieces of political satire show us French and English exchanging amenities on their mutual shortcomings. The *Roman des Français*, by André de Coutances, was written on the Continent, and cannot be quoted as Anglo-Norman although it was composed before 1204 (*cf.* Gaston Paris: *Trois versions rimées de l'évangile de Nicodème*, *Soc. Anc. Textes*, 1885). It is a very spirited reply to French authors who had attacked the English.

Dramatic literature must have had a considerable influence on the development of the sacred drama in England, but none of the French plays acted in England in the 12th and 13th centuries has been preserved. *Adam*, which is generally considered to be an Anglo-Norman mystery of the 12th century, was probably written in France at the beginning of the 13th century (*Romania* xxii. 637), and the so-called Anglo-Norman *Resurrection* belongs also to continental French. It is necessary to state that the earli-

est English moralities seem to have been imitations of the French.

Didactic and hagiographic literature are represented by numerous works, a complete list of which will be found in Johan Vising's *Anglo-Norman Language and Literature*.

BIBLIOGRAPHY.—J. Vising, *Anglo-Norman Language and Literature* (1923); O. H. Prior, "Remarques sur l'anglo-normand" (*Romania*, 1923); J. P. Strachey, *Poem on the Assumption*, H. J. Chaytor, *Poem on the day of Judgment*, D. H. Prior, *Divisiones Mundi*; these three pieces are published in *Cambridge Anglo-Norman Texts* (1924).

(L. B.)

ANGLO-PERSIAN OIL COMPANY, LTD. This company was registered in London in 1909 to work a concession (originally obtained from the Persian Government by William Knox D'Arcy), which runs for 60 years from May 28, 1901, and gives the exclusive right to drill for, produce, pipe and carry away natural gas, petroleum, asphalt, etc., throughout the Persian empire, except in the provinces of Azarbaijan, Gilan, Mazandaran, Astrabad and Khurāsān, *i.e.*, an area of about 500,000 square miles.

After much unsuccessful drilling in the neighbourhood of Qasr-i-Shirin and elsewhere, oil was struck in large quantities in the year 1908 at Masjid-i-Sulaiman, about 30m. east of Shuster in the province of Khuzistan (south-west Persia). By 1913 the company was in need of further capital and, as the British Admiralty was then anxious to secure fresh sources of supply for its fuel oil, the Government entered into an agreement; important supply contracts still subsist between the Admiralty and the company.

Through the British Tanker Co., Ltd. the Anglo-Persian Oil Co., Ltd. controls some 80 tank steamers, all built in Great Britain, and having a total carrying capacity of over 700,000 tons; and through subsidiary companies it operates refineries in South Wales, Scotland, and (through associated companies) in France, Australia and Argentina. The greater part of the present crude production is refined at Abadan in Persia. The company's main production is still obtained from Masjid-i-Sulaiman and is conveyed by pipe lines to its refinery at Abadan on the Shatt-el-Arab, a distance of 145 miles. A limited production of oil is also obtained by the company at Naft Khana in Iraq. This particular oil-field may be found to extend into Persian territory.

The main Persian oil belt, in which oil has been proved in a total area of 30 sq. m., comprises a tract which extends into Iraq and there appears to be a fundamental geological concordance throughout the whole belt. The production of oil from the Persian field for the years ending March 1921-27 was as follows: (tons) 1,743,557, 2,327,221, 2,959,028, 3,714,216, 4,333,933, 4,556,157, 4,806,667—all obtained from large flowing wells, others being held in reserve to meet the constant expansion of the company's trade.

Of the yearly net profits 16% is payable to the Persian Government, who have received on this account the following sums:

Year ended		Year ended	
March	£	March	£
1921	585,290	1925	824,086
1922	593,429	1926	1,048,135
1923	533,251	1927	1,341,963
1924	377,575		

The company employs in Persia 26,000 persons, most of whom are Persians.

ANGLO-SAXON CHRONICLE. It is usual to speak of "the Anglo-Saxon Chronicle"; it would be more correct to say that there are four Anglo-Saxon Chronicles. It is true that these all grow out of a common stock, that in some even of their later entries two or more of them use common materials; but the same may be said of several groups of mediaeval chronicles, which no one dreams of treating as single chronicles. Of this fourfold Chronicle there are seven mss. in existence: C.C.C. Cant. 173 (A); Cott. Tib. A vi. (B); Cott. Tib. B i. (C); Cott. Tib. B iv. (D); Bodl. Laud. Misc. 636 (E); Cott. Domitian A viii. (F); Cott. Otho B xi. (G). Of these G is now a fragment, and it is known to have been a transcript of A, while A, C, D, E have every right to be treated as independent chronicles. The rela-

tions between the four vary very greatly in different parts, and the neglect of this consideration has led to much error and confusion. The common stock, out of which all grow, extends to 892. There seems to be no reason to doubt that the idea of a national, as opposed to earlier local chronicles, was inspired by Alfred, who may even have dictated, or at least revised, the entries relating to his own campaigns; while for the earlier parts pre-existing materials, both oral and written, were utilized. The impulse given by Alfred was continued under Edward, and we have what may be called an official continuation of the history of the Danish wars, which, in B, C, D extends to 915, and in A to 924. After 915 B, C insert as a separate document a short register of Mercian affairs during the same period (902-924), which might be called the acts of Aethelflaed, the famous "Lady of the Mercians," while D has incorporated it, not very skilfully, with the official continuation. From 925 to 975 all the chronicles are very fragmentary; a few obits, three or four poems, among them the famous ballad on the battle of Brunanburh, make up the meagre tale of their common materials. From 983 to 1018 C, D and E are practically identical, and give a connected history of the Danish struggles under Aethelred II. This section was probably composed at Canterbury. From 1018 the relations of C, D, E become too complicated to be expressed by any formula; sometimes all three agree together, sometimes all three are independent; in other places each pair in turn agree against the third. It may be noted that C is strongly anti-Godwinist, while E is equally pro-Godwinist, D occupying an intermediate position. C extends to 1066, where it ends abruptly, and is probably mutilated. D ends at 1079 and is certainly mutilated. In its later history D is associated with some place in the diocese of Worcester, probably Evesham. In its present form D is a comparatively late ms., none of it probably much earlier, and some of it later, than 1100. In the case of entries in the earlier part of the chronicles, which are peculiar to D, we cannot exclude the possibility that they may be late interpolations. E is continued to 1154. In its present form it is unquestionably a Peterborough book. The earlier part is full of Peterborough interpolations, to which place many of the later entries also refer. But (apart from the interpolations) it is only the entries after 1121, where the first hand in the ms. ends, which were actually composed at Peterborough. The section 1023-67 certainly, and possibly also the section 1068-1121, was composed at St. Augustine's, Canterbury; and the former is of extreme interest and value, the writer being in close contact with the events which he describes. The later parts of E show a great degeneration in language, and a querulous tone due to the sufferings of the native population under the harsh Norman rule.

BIBLIOGRAPHY.—The above account is based on the introduction in vol. ii. of the Rev. C. Plummer's edition of *Two of the Saxon Chronicles Parallel* (1892, 1899); to which the student may be referred for detailed arguments. The *editio princeps* of the Anglo-Saxon Chronicle was by Abraham Wheloc (1643-44). In 1861 appeared Benjamin Thorpe's six-text edition in the Rolls Series. Though not free from defects, this edition is absolutely indispensable. A second volume contains the translation. The best translation is that by the Rev. Joseph Stevenson, in his series of *Church Historians of England* (1853). An *Anglo-Saxon Chronicle*, edited by E. Classen and F. E. Harmer (1926) is a useful reprint of D with emendations and notes.

ANGLO-SAXON LAW. The body of legal rules and customs which obtained in England before the Norman Conquest constitutes, with the Scandinavian laws, the most genuine expression of Teutonic legal thought. While the so-called "barbaric laws" (*leges barbarorum*) of the Continent, not excepting those compiled in the territory now called Germany, were largely the product of Roman influence, the continuity of Roman life was almost completely broken in the island, and even the Church, the direct heir of Roman tradition, did not carry on a continuous existence: Canterbury was not a see formed in a Roman province in the same sense as Tours or Reims. One of the striking expressions of this Teutonism is presented by the language in which the Anglo-Saxon laws were written. They are uniformly worded in English, while Continental laws, apart from the Scandinavian, are all in Latin. The English dialect in which the Anglo-Saxon laws have been

handed down to us is in most cases a common speech derived from West Saxon—naturally enough as Wessex became the predominant English State. Traces of Kentish speech may be detected, however, in the *Textus Roffensis*, the ms. of the Kentish laws, and Northumbrian dialectal peculiarities are also noticeable, while Danish words occur as technical terms. At the conquest Latin takes the place of English in the compilations made to meet the demand for Anglo-Saxon law texts as still applied in practice.

Classification.—It is easy to group the Anglo-Saxon laws according to the manner of their publication. They would fall into three divisions: (1) laws and collections of laws promulgated by public authority; (2) statements of custom; (3) private compilations of legal rules and enactments. To the first division belong the laws of the Kentish kings, Aethelbert, Hlothhere and Eadric, Wihtraed; those of Ine of Wessex, of Alfred, Edward the Elder, Aethelstan, Edmund, Edgar, Aethelred and Canute; the treaty between Alfred and Guthrum and the so-called treaty between Edward and Guthrum. The second division would include the law of the Northumbrian priests and fragments of local customals entered in Domesday Book. The third division would consist of the post-Conquest collections of the so-called *Pseudo-leges Canuti*, the laws of Edward the Confessor, of Henry I., and the great compilation of the *Quadripartitus*, then of a number of short notices on various matters, such as the formalities of betrothal (*Be-wifmannes beweddunge*), agricultural conditions (*Rectitudines singularum personarum*), the duties of a reeve (*gerefa*) and of a judge (*dema*), wergelds, oaths, ordeals, etc. A fourth group might be made of the charters, as they are based on Old English private and public law and supply us with most important materials in regard to it. Looking somewhat deeper at the sources from which Old English law was derived, we shall have to modify our classification to some extent, as the external forms of publication, although important from the point of view of historical criticism, are not sufficient standards as to the juridical character of the various kinds of material. Direct statements of law would fall under the following heads, from the point of view of their legal origins: i. customary rules followed by divers communities capable of formulating law; ii. enactments of authorities, especially of kings; iii. private arrangements made under recognized legal rules. The first would comprise a great many of the rules entered in collections promulgated by kings; most of the paragraphs of Aethelbert's, Hlothhere's, and Eadric's and Ine's laws are popular legal customs that have received the stamp of royal authority by their insertion in official codes. On the other hand, from Wihtraed's and Alfred's laws downwards, the element of enactment by central authority becomes increasingly prominent, though there are no outward signs enabling us clearly to distinguish between both categories of laws in the codes, nor can we draw a line between permanent laws and personal ordinances of single sovereigns, as has been attempted in the case of Frankish legislation.

Analysis of Content.—Even in the course of a general survey of the legal lore at our disposal, one cannot help noticing that matters which seem to us of primary importance are almost entirely absent in Anglo-Saxon laws. A brief analysis of the contents of royal codes and laws may be found instructive.

In these codes the paragraphs devoted to criminal law and procedure far outnumber those concerned with matters of private law and civil procedure. A very large number of the criminal law clauses are concerned with tariffs of fines, while a considerably smaller number deal with punishments, such as outlawry, confiscation of property, mutilation and death. Private law is concerned mainly with contracts (including marriage) and matters connected with property. Questions of public law and administration (concerned chiefly with the power and privileges of the king, with police regulations and, to a much less extent, with local administration and purely economic and fiscal matters) are frequently discussed. Clauses which concern the Church (in collections not purely ecclesiastical) appear time and again, most commonly in the form of general precepts based on religious and moral considerations. A certain number, however, relate to secular privileges conferred on the Church and to matters of organization.

A consideration of chronological sequence in the elaboration of

the laws reveals interesting results. The code of Aethelbert is almost entirely a list of fines or "compositions" for various crimes, and similar lists figure largely in the laws of Hlothhere and Eadric, Ine and Alfred. In the codes of Edward the Elder and his successors, however, lists of fines for criminal offences are much less prominent, and gradually a new penal system is evolved, based on outlawry, confiscation, capital and corporal punishment.

Fines and compensations throughout the laws are carefully graded, in accordance with the social standing of the persons concerned. In early times it would appear that the different classes of society were more sharply distinguished than they were later. From the time of Aethelstan onwards the distinction between the *thegn* or *twelfhynde* man (*i.e.*, the man with a wergeld of 1,200 shillings) and the *ceorl* or *twihynde* man (*i.e.*, the man with a wergeld of 200 shillings) is the chief dividing line between the classes of society. In the arrangements of the commonwealth the clauses treating of royal privileges are more or less evenly distributed over all reigns, but the systematic development of police functions, especially in regard to responsibility for crimes, the catching of thieves, the suppression of lawlessness, is mainly the object of 10th and 11th century legislation. The reign of Aethelred, which witnessed the greatest national humiliation in English history, is also marked by the most lavish expressions of religious feeling and the most frequent appeals to morality. Such an analysis of the Old English laws is by no means complete, but will convey some idea of the trend of State legislation during the period.

Derivation.—The next question to be approached concerns the pedigree of Anglo-Saxon law and the latter's natural affinities. How far has it been influenced by non-Germanic elements, especially by Roman and Canon law? The oldest Anglo-Saxon codes, especially the Kentish and the West Saxon ones, disclose a close relationship to the barbaric laws of Lower Germany—those of Saxons, Frisians, Thuringians. We find a division of social ranks which reminds us of the threefold gradation of Lower Germany (*edelings*, *frilings*, *lazzen*—Kentish *eorls*, *ceorls*, *laets*), and not of the twofold Frankish one (*ingenii Franci*, *Romani*), nor of the minute differentiation of the Upper Germans and Lombards. In subsequent history there is a good deal of resemblance between the capitularies' legislation of Charlemagne and his successors on one hand, the acts of Alfred, Edward the Elder, Aethelstan and Edgar on the other, a resemblance called forth less by direct borrowing of Frankish institutions than by the similarity of political problems and conditions. Frankish law becomes a powerful modifying element in English legal history after the Conquest, when it was introduced wholesale in royal and in feudal courts. The Scandinavian invasions brought in many northern legal customs, especially in the districts thickly populated with Danes. The Domesday survey of Lincolnshire, Nottinghamshire, Yorkshire, Norfolk, etc., shows remarkable deviations in local organization and justice (*lagmen*, *sokes*), and great peculiarities as to status (*socmen*, *freemen*), while from laws and a few charters we can perceive some influence on criminal law (*nidingsvaerk*), special usages as to fines (*lahslit*), the keeping of peace, attestation and sureties of acts (*festermen*), etc. But, on the whole, the importance of the introduction of Danish and Norse elements, apart from local cases, is owing chiefly to the conflicts and compromises it called forth and its social results; the Scandinavians coalesced easily with the natives.

The direct influence of Roman law was not great during the Saxon period: we notice neither the transmission of important doctrines, nor the continuous stream of tradition in local usage. But indirectly Roman law did exert a by no means insignificant influence through the medium of the Church, which for all its insular character, was still permeated with Roman ideas and forms of culture. The Old English "books" are derived in a roundabout way from Roman models, and the tribal law of real property was deeply modified by the introduction of individualistic notions as to ownership, donations, wills, rights of women, etc. Yet here also the Norman Conquest increased the store of Roman conceptions by breaking the isolation of the English Church and opening the way for closer intercourse with France and Italy.

Folk-right and Privilege.—It would be useless to attempt to trace in a brief sketch the history of the legal principles embodied in the documents of Anglo-Saxon law. But it may be of some value to give an outline of a few particularly characteristic subjects. The Anglo-Saxon legal system cannot be understood unless one realizes the fundamental opposition between folk-right and privilege. Folk-right is the aggregate of rules, formulated or latent but susceptible of formulation, which can be appealed to as the expression of the juridical consciousness of the people at large or of the communities of which it is composed. It is tribal in its origin, and differentiated, not according to boundaries between States, but on national and provincial lines. There may be the folk-right of West and East Saxons, of East Angles, of Kentish men, Mercians, Northumbrians, Danes, Welshmen, and these main folk-right divisions remain even when tribal kingdoms disappear. The centres for the formulation and application of folk-right were in the 10th and 11th centuries the shire-moots, while the councillors (*witan*) of the realm generally placed themselves on the higher ground of State expediency, although occasionally using folk-right ideas. The older law of real property, of succession, of contracts, the customary tariffs of fines, were mainly regulated by folk-right; the reeves employed by the king and great men were supposed to take care of local and rural affairs according to folk-right. The law had to be declared and applied by the people itself in its communities, while the spokesmen of the people were the leading men—the 12 eldest thanes or a similar quorum. Folk-right could, however, be broken or modified by special law or special grant, and the fountain of such privileges was the royal power. Alterations and exceptions were, as a matter of fact, suggested by the interested parties themselves, and chiefly by the Church. Thus a privileged land-tenure was created—bookland; the rules as to the succession of kinsmen were set at naught by concession of testamentary power and confirmations of grants and wills; special exemptions from the jurisdiction of the hundreds and special privileges as to levying fines were conferred. In time the rights originating in royal grants of privilege overbalanced folk-right in many respects, and became the starting-point of a new legal system—the feudal one.

The King's Peace.—Another feature of vital importance in the history of Anglo-Saxon law is its tendency towards the preservation of peace. Society is constantly struggling to ensure the main condition of its existence—peace. Already in Aethelbert's legislation we find characteristic fines inflicted for breach of the peace of householders of different ranks—the *ceorl*, the *eorl* and the king himself appearing as the most exalted among them. Peace is considered not so much a state of equilibrium and friendly relations between parties, but rather as the rule of a third within a certain region—a house, an estate, a kingdom. This leads on one side to the recognition of private authorities—the father's, the master's, the lord's—while, on the other, the tendency to maintain peace naturally takes its course towards the strongest ruler, the king, and we witness the gradual evolution of stringent rules in respect of the king's peace.

The more ancient documents of Anglo-Saxon law show us the individual not merely as the subject and citizen of a certain commonwealth, but also as a member of some group, all the fellows of which are closely allied in claims and responsibilities. The most elementary of these groups is the *maegth*, the association of agnatic and cognatic relations. Personal protection and revenge, oaths, marriage, wardship, succession, supervision over settlement and good behaviour, are regulated by the law of kinship. A man's actions are considered not as exertions of his individual will, but as acts of the kindred, and all the fellows of the *maegth* are held responsible for them. What began as a natural alliance was used later as a means of enforcing responsibility and keeping lawless individuals in order. When the association of kinsmen failed (and it seems to have done so at an early period in England), the voluntary associations—gilds—appeared as substitutes. The gild brothers associated in mutual defence and support, and they had to share in the payment of fines. The township and the hundred came in also for certain forms of collective responsibility.

In course of time the natural associations get loosened and in-

termixed, and this calls forth the elaborate police legislation of the later Anglo-Saxon kings. Regulations are issued about the sale of cattle in the presence of witnesses. Enactments about the pursuit of thieves, and the calling in of warrantors to justify sales of chattels, are other expressions of the difficulties attending peaceful intercourse. Personal surety appears as a complement of and substitute for collective responsibility. The *hlaford* and his *hiredmen* are an institution not only of private patronage, but also of police supervision for the sake of laying hands on malefactors and suspected persons. The *landrica* assumes the same part in a territorial district. Ultimately the laws of the 10th and 11th centuries show the beginnings of the frankpledge associations, which came to act so important a part in the feudal age.

(P. VI.; A. J. R.)

ANGLO-SAXONS. The term "Anglo-Saxon" is commonly applied to that period of English history, language and literature which preceded the Norman Conquest. It goes back to the time of King Alfred, who seems to have frequently used the title *rex Anglorum Saxonum* or *rex Angul-Saxonum*. The origin of this title is not quite clear. It is generally believed to have arisen from the final union of the various kingdoms under Alfred in 886. Bede (*Hist. Eccl.* i. 15) states that the people of the more northern kingdoms (East Anglia, Mercia, Northumbria) belonged to the Angli, while those of Essex, Sussex and Wessex were sprung from the Saxons (*q.v.*), and those of Kent and southern Hampshire from the Jutes (*q.v.*). Other early writers, however, do not observe these distinctions, and neither in language nor in custom do we find evidence of any appreciable differences between the two former groups, though in custom Kent presents most remarkable contrasts with the other kingdoms. Still more curious is the fact that West Saxon writers regularly speak of their own nation as a part of the *Angelcyn* and of their language as *Englisc*, while the West Saxon royal family claimed to be of the same stock as that of Bernicia. On the other hand, it is by no means impossible that the distinction drawn by Bede was based solely on the names Essex (East Seaxan), East Anglia, etc. We need not doubt that the Angli and the Saxons were different nations originally; but from the evidence at our disposal it seems likely that they had practically coalesced in very early times, perhaps even before the invasion.

See W. H. Stevenson, *Asser's Life of King Alfred* (1904, pp. 148 seq.); H. Munro Chadwick, *The Origin of the English Nation* (1907); also *BRITAIN: Anglo-Saxon*. (H. M. C.)

ANGOLA, the general name of Portuguese possessions in West Africa south of the equator. The name (a Portuguese corruption of the Bantu *Ngola*) is sometimes confined to the 105m. of coast, with its hinterland, between the rivers Dande and

Kwanza; but is officially applied to a whole province situated south of the Congo save for the enclave of Kabinda (Portuguese *Cabinda*). It extends about 1,000m. along the coast from the Congo (6° S., 12° E.) its northern frontier for 80m., to the mouth of the Kunene (Cunene) river (17° 18' S., 11° 50' E.). From the Congo the frontier goes due east to the Kwango river. The eastern boundary, dividing Angola from the Belgian Congo and Barotseland (North-west Rhodesia), is highly irregular. Angola's border towards South-west Africa, somewhat south of 17° S. lat., is being demarcated (1928) jointly by the Portuguese and Union of South Africa Governments, while a study is being made of the deviation of the Kunene waters towards Damaraland. By a recent convention Portugal ceded a small area south of the Congo, near Matadi, for laying the Boma-Leopoldville railway; Belgium gave in exchange about 3,000sq.km. of the Bota de Dilolo, the Congo frontier passing behind and almost parallel to the river Luao. This helps construction of the Angola-Katanga railway. The area is given as 1,256,000sq.km. The population (1927) is something over 4,000,000, among whom are 35,000–40,000 Europeans, mostly officials.

Physical Features.—The coast is for the most part flat, with occasional low cliffs of red sandstone. Great Fish bay (or Bahia dos Tigres), a little north of the Portuguese South-west African frontier, is the one deep inlet. Farther north are Port Alexander, Little Fish bay and Lobito bay, while shallower bays are numerous. Lobito bay allows large ships to unload close inshore. The sparsely watered, sterile coast plain extends 30–100m. inland. The great central plateau of Africa is approached by a series of irregular terraces, covered with luxuriant vegetation. Water is fairly abundant, though in the dry season obtainable only by digging in the sandy beds of the rivers. The plateau, of altitude 4,000 to 6,000ft., consists of well-watered, wide, rolling plains and low hills with scanty vegetation. In the east the tableland falls away to the basins of Congo and Zambezi; to the south it merges into barren sandy desert. The numerous westward rivers, save the Kwanza and Kunene (*q.v.*), are unimportant. The mountain chains, edging or dominating the plateau run generally parallel to the coast, as Tala Mugongo (4,400ft.), Chella and Vissecua (5,250ft. to 6,500ft.). In the district of Benguella are the highest points of the province, viz., Loviti (7,780ft.), in 12° 5' S., and Mt. Elonga (7,550ft.). South of the Kwanza is the volcanic mountain Caculo-Cabaza (3,300ft.). From the tableland the Kwango and many other streams flow north to join the Kasai (one of the largest affluents of the Congo), which, in its upper course, forms for fully 300m. the boundary between Angola and the Congo State. In the south-east the rivers flow to the Zambezi or, like the Okavango, drain to Lake Ngami.

Geology.—The central plateau consists of ancient crystalline rocks with granites overlain by unfossiliferous sandstones and conglomerates considered to be of Palaeozoic age. The outcrops are largely hidden under laterite. The median zone of hills parallel with the coast is composed largely of crystalline rocks with granites and some Palaeozoic unfossiliferous rocks. The littoral zone contains the only fossiliferous strata; they are of Tertiary and Cretaceous ages, the latter rocks resting on a reddish sandstone of older date. The Cretaceous rocks of the Dombe Grande region (near Benguella) are of Albian age and belong to the *Acanthoceras mamillari* zone. The beds containing *Schloenbachia inflata* are referable to the Gault. Tertiaries are met with at Dombe Grande, Mossamedes and near Loanda. The sandstones with gypsum, copper and sulphur of Dombe may be Triassic. Recent eruptive rocks, mainly basalts, form a line of hills almost bare of vegetation between Benguella and Mossamedes. Nepheline basalts and liparites occur at Dombe Grande. Gum copal occurs in quantity in some superficial rocks.

Minerals.—Thick beds of copper are found at Bembe, and deposits on the M'Brija and the Cuvo and in various places in the south. Iron is known in many parts, chiefly at Oeiras (on the Lucalla affluent of the Kwanza) and in Bailundo. It is worked by native blacksmiths, who are held in high repute. A foundry at Oeiras has undergone important development. Concessions for petroleum and asphalt have been granted to British syndicates

and active prospecting is proceeding near the rivers Dande and Kwanza and Baixo Amboim. Mineral salt is worked by natives in several places, e.g., Quissama. Gold occurs in Lombije and Kas-singa, lead at Caxibo and lignite in the valley of the Kwanza. Coal is found at Calucala, Quilungo, Dondo and Chapeu Armado. The output is absorbed by the railways. Diamonds are worked in Lunda under concession from the Government which shares in the profits. Fifty-five Europeans and 5,000 natives are employed (1927), the production being 101,509 carats in 1927. Other minerals known to occur in Angola are silver, manganese and sulphur.

Climatic.—With the exception of the district of Mossamedes, the coast plains are unsuited to Europeans. In the interior, above 3,300ft., temperature and rainfall, together with malaria, decrease. The plateau climate is healthy and invigorating. The mean annual temperature at São Salvador do Congo is 72.5°; at Loanda, 74.3°, and at Caconda, 67.2°. The prevailing winds are west, south-west and south-south-west. The cool season lasts from June to September; and the rainy, from October to May; the heaviest rainfall occurs with storms in April.

Flora and Fauna.—As far south as Benguella the coast is rich in oil-palms and mangroves. In the north are dense forests, in the south, towards the Kunene, regions of dense thorn scrub. Rubber vines and trees are abundant, but have been reduced by the ruthlessness of native collectors; the commonest are various root rubbers, notably *Carpodinus chylorrhiza*; *Landolphia* are also found. Coffee, cotton and Guinea pepper are indigenous, and tobacco flourishes in several districts. Among timber trees are the *tacula* (*Pterocarpus tinctorius*), which grows to an immense size, its wood being blood-red in colour, and the Angola mahogany. The bark of the musuamba (*Albizia coriaria*) is used in tanning leather. The mulundo bears a hard green-shelled fruit like a cricket ball, with scarlet pips like a pomegranate. The fauna includes lion, leopard, cheetah, elephant, giraffe, rhinoceros, hippopotamus, buffalo, zebra, kudu and many other kinds of antelope, wild pig, ostrich and crocodile. Among fish are the barbel, bream and African yellow fish.

Inhabitants.—Portuguese predominate very greatly in the European population, but the Dutch in the interior at Humpata number over 2,000. Portuguese immigration at present averages a little over 200 per month. The great majority of the inhabitants are of Bantu-Negro stock mixed in the Congo district with the pure Negro. In the south-east are various tribes of Bushmen. Bantu-Negroes include the Ba-Kongo (Ba-Fiot) in the north, and the Abunda (with Portuguese admixture) (Mbunda, Ba-Bundo), in the centre. The Bangala, west of the upper Kwango, must not be confounded with the Bangala of the middle Congo. The Ba-Lunda inhabit the Lunda district. The Mushi-Kongo and other divisions of the Ba-Kongo were Christian in the 16th and 17th centuries and possibly later, and they use crucifixes as fetish charms or as symbols of power, whilst every native has a "Santu" or Christian name and is dubbed dom or dona. Fetichism is the prevailing religion throughout the province. The natives have usually small simple huts, used for sleeping; the day is spent in an open space in front of the hut protected from the sun by a roof of palm or other leaves. Native languages reduced to writing are Kisi Kongo (in the north), Kimbundu (north central), Umbundu (highlands east of Lobito) and Luchazi (south). A considerable mulatto population, growing in number and importance, is settled mainly in the coast areas.

Administration and Government.—A high commissioner, resident at present in Loanda, and appointed by the Lisbon Government, has powers wider than those of the former governor-general, and similar to those of the colonial minister, granted

expressly for the solution of stated questions of administration. Under the high commissioner are the district governors. The province is divided into the following districts: Loanda, Benguella, Bié, Congo, Cuanza-Norte, Cuanza-Sul, Huila, Cubango, Lunda, Malange, Mossamedes, Moxico, Luchazes, Zaire. (Lunda is part of the old Bantu kingdom of Muata Yanvo, divided by international agreement between Portugal and the Congo Free State.) Each district is divided into civil circumscriptions, each under an administrator, who is resident magistrate. In each circumscription, responsible to the administrator, are "chefes do posto," responsible for outlying posts. A local legislative council founded in 1922 has colonist representatives; it acts except in such matters as are reserved to the congress of the republic, or in general measures affecting more than one colony. Gen. Norton de Mattos, high commissioner 1921-24, initiated a scheme with development of communications, immigration of Portuguese settlers, supervision of foreign immigrants, introduction of Portuguese municipal institutions, inclusion of the Congo customs service in that of Angola, thus unifying the province, progressive native policy, health services, improved military organization, education—especially technical education—scientific services, strict supervision of concessions, regulation of religious missions and the raising of loans. This policy was adversely criticized, and, since de Matos' resignation, only part has been carried out. The administrative personnel has been reduced; but recruiting and promotion have been improved.

There are plans for industrializing State railways, for a tariff system to benefit exporting producers, and for separating charges of first establishment from running costs. A commission has been appointed to assist the natives, mainly medically, and technical staffs are being improved. The public services are divided into 13 directorships and five departments, concentrated at Loanda, with delegations in the districts. Angola constitutes a judicial district, with nine subdivisions, each in charge of a judge of first instance. There is an appeal court at Loanda.

Ecclesiastical.—The province forms a diocese of the Roman Catholic Church, in the province of Lisbon. This church began work at São Salvador in 1491, and controlled all educational activities till 1908. Since 1852 the Society of the Holy Ghost has carried on work in the Benguella district. The Society of the Sacred Heart has a station at Huila, in the Mossamedes district, and some mission schools. The Baptist Missionary Society has headquarters at São Salvador. The American Methodist Episcopal Foreign Missionary Society works in the Loanda district, and the Canadian and American Congregational Churches and the Plymouth, Brethren Mission in the highlands east of Lobito bay. In the Mossamedes district are stations of the South Africa General Mission and the Swiss Mission. The missions have schools, especially for agriculture.

Military Organization.—The military force consists of one battery of artillery, two mixed companies of infantry and artillery, one squadron of cavalry (on the plateau of Mossamedes), one company of European infantry, 16 companies of native infantry, one police force (Loanda) and one disciplinary battalion.

Public Instruction.—There are 52 Government schools, seven municipal and private schools, one seminary under an important mission at Huila, one principal secondary school and primary schools in all districts, a technical school for male natives in the circumscription of Cachingues, one for female natives at Malange and one for natives of both sexes in the circumscription of Alto Cuanza. Mixed primary schools for whites exist at Malange, Cangoma, Monongue (in the Cubango district), Silva Porto and at Humpata, the last having been doubled in size. 3,500 children (1,300 whites, the rest mainly mulatto) attend official primary schools. Native education is almost entirely in the hands of missions. A decree of 1921 prohibits teaching of native languages and printing of books of religion or instruction in native languages. This has been so far relaxed as to allow of the printing of a few books bilingually—in Portuguese and a native language.

Health.—Sleeping-sickness appears especially in the north-east and on the coast between Lobito and Benguella. Common diseases are malaria, hookworm, smallpox, leprosy, elephantiasis

BY COURTESY OF THE PHELPS-STOKES FUND
A NATIVE MUSICIAN OF ANGOLA
The African races are fond of music, and some of their musical instruments, though primitive in construction, produce tones of haunting sweetness

and goitre among the women of the uplands. There are hospitals at Loanda and other coast towns, and several mission hospitals. A "travelling health mission" in the Congo district began work in Sept. 1927 for Melange and Marimba; another is being prepared for Zaire, Congo and the Cabinda enclave. There is a special fund for medical assistance to natives.

Chief Towns.—Until 1927, Loanda (São Paulo de Loanda), an excellent port, was the capital of the province of Angola. It is 8° 48' S., 13° 7' E., on a bay between the rivers Bango and Kwanza. The bay, protected from the surf by a long narrow island of sand, is backed by a low sandy cliff which sweeps sharply southward to a bold point crowned by Ft. São Miguel. The bay has silted up considerably, but there is a good anchorage about 1½ m. from the shore in 7 to 14 fathoms, and the depth at the entrance is 20 fathoms. Vessels discharge into lighters, and are rarely delayed by weather. Part of the town lies on the foreshore, but the offices, governor's residence, bishop's palace and hospital are on higher ground. Most European houses are large stone buildings of one storey with red tile roofs. Loanda possesses a meteorological observatory.

Loanda was founded in 1576, and except between 1640 and 1648, when it was occupied by the Dutch, has always been in Portuguese possession. It was the chief centre of the slave trade between Portuguese West Africa and Brazil but suppression of that trade caused depression for a time. There is a regular service to Lisbon (16 days), Liverpool and Hamburg. The town's 16,000 inhabitants include a larger European element than any other place on the west coast of Africa. It is connected by submarine cables with Europe and South Africa. Fully half the import and export trade of Angola passes through Loanda. In Nov. 1927 it was announced that the capital was to be transferred to Huambo, a modern town created by the Benguella railway, 266 m. from the coast. This is now an important administrative, trading and railway centre, with wireless station and aerodrome. Lobito, 20 m. north of Benguella, was founded 1905, because its bay was chosen as the terminus of the Benguella railway. It has 429 hectares of anchorage, and a quay at which three steamers can lie and discharge cargo direct. Lobito is connected with Benguella by a railway through Katumbella, a town at the mouth of the river of the same name, and the sea terminus of an ancient route from the heart of Central Africa through Bié. Old Benguella is a town about 120 m. north of Lobito bay. Other chief towns are, in the district of Congo: Cabinda, a good port and capital of the district; Landana, a port north of the Zaire; São Salvador do Congo (4,000), an ancient town, capital of the old kingdom of Congo, and formerly called Bonza Congo, 1,840 ft. above sea-level, and about 160 m. inland, and 100 m. S.E. of Noki (*q.v.*) in 6° 15' S. Only scanty ruins remain of the cathedral of the 16th century. The stone of the city walls was used recently to build Government offices; a fort was built about 1850. Ambrizete is a small port south of the Zaire river; Noki is at the head of navigation on the south bank of the Congo and takes large ships. In the district of Loanda: Ambriz, at the mouth of the Loje river, in 7° 50' S., 13° E., some 70 m. N. of Loanda, lies within the free-trade area of the conventional Congo basin and exports rubber, gum, coffee and copper; its population is 2,500. Ambaca in the district of Cuanza Norte, east of Loanda, and connected with it by railway, in a fertile agricultural district; Cazungo, capital of the best coffee district; Dondo (4,000), a commercial town on the right bank of the Kwanza, communicating with Loanda by steamer; Novo Redondo, a small port south of Loanda. In the district of Benguella: Benguella (São Felipe de Benguella) capital of the district, on a bay of the same name, in 12° 33' S., 13° 25' E., was founded in 1617 by the Portuguese under Manoel Cerveira Pereira. It was long the centre of the slave trade to Brazil and Cuba, but has now greatly declined. The anchorage, about a mile from the town, in four to six fathoms, is nothing but an open roadstead. The white population numbers about 4,000. A short way beyond Benguella is Bahia Tarta, where salt is manufactured and sulphur excavated. Caconda, south-west of Benguella, on a plateau, is a commercial centre; Bié, east of Benguella, is capital of the fertile and healthy district of the same

name, and a large caravan centre; Kangomba, the residence of the former kings of Bié, is a large town; Catumbela is a port north of, and near, Benguella. In the district of Mossamedes: Mossamedes, capital of the district, on the south side of Little Fish bay (Bay of Mossamedes or Angra do Negro) is a healthy port, with a harbour affording excellent anchorage (pop. 5,000). A railway (248 km. in use) starts from the harbour and crosses the semi-desert coast-region to the fertile Chela plateau. Mossamedes is the headquarters of an important fishing industry. Porto Alexandre is south of Mossamedes. In the district of Huila,

BY COURTESY OF THE PHELPS-STOKES FUND

A PALISADED VILLAGE OF THE TYPE CONSTRUCTED BY ANGOLA NATIVES
The huts, fairly uniform in size, are built of mud and roofed with and surrounded by a palisade whose gates are barred at nightfall

capital of an elevated, very healthy and fertile district, recently created out of the territories of Mossamedes, capable of growing European plants, Humpata, about 95 m. N.E. of Mossamedes, with Dutch settlers, produces cereals and tobacco. In the district of Malange is Malange, provisional capital of the district, 120 km. from Ambaca. Capenda-Camalembe is to be the future capital of the Loanda district.

Economic and Financial.—Credit was badly damaged in 1924–26 but the situation is improving. Revenue, chiefly from customs, excise duties and direct taxation, is generally less than expenditure, which is, however, partly on railways and other productive works. The natives pay, throughout the territory, a single tax of 80 escudos. State debts, partly capital for development, amount to 140,260 contos (Angolese), costing in service 14,815 contos per annum. The cost of civil administration is 17,767 contos. The Bank of Angola is being strengthened, a Land Bank has been founded and a new stable currency is to be decreed.

The Lisbon Government has assumed responsibility for deficits for four years after 1928, hoping that intensified production and restriction of imports will make budgets balance. An issue of short-period Treasury notes payable on demand has been well received.

Returns of general commerce in 1926 showed (in Lisbon currency) a decrease of 27,577 contos in imports and of 45,170 in exports, the totals being imports 225,569 contos, and exports 188,459 contos. The chief goods imported were, in order of value, common wines, railway material, cement, iron and steel, flour and cotton cloths. The chief exports were maize, sugar, coffee, dried fish, coconuts, palm oil and wax. Diamonds valued at £346,251 were exported. Exports to S. Thomé and Príncipe were valued at 9,931 contos.

The balance of trade in 1926 showed an excess of imports over exports of 37,110 contos (Lisbon currency). Excluding material for the Benguella railway and the port of Lobito the excess of imports over exports in 1926 was 622 contos. Three-quarters of the exports go to Portugal. In 1925, 23% was exported under foreign flags. In the last seven years, the value of imports of national origin has almost always exceeded that of those of foreign origin. The tonnage of goods imported in foreign ships has tended to decrease since 1923, but the total value of goods imported and exported in German ships has risen from 645 contos in 1920, to 42,002 contos in 1926, beer being an important item. Maize exported in 1926 was valued at 22,589 contos. The returns of the Bank of Angola showed, in March 1927, a balance of about 50,000 contos (Portuguese) against the colony. Gold is beginning to enter

the province in important amounts.

Ports and Shipping.—There is regular steamship communication between Portugal, England, Germany and Loanda. There is also a regular service between Cape Town, Lobito and Lisbon and Southampton. The Portuguese line is subsidized by the Government. Coastwise traffic and river navigation need development. Only in the port of Lobito is there a quay to which ships can moor. Plans are being made for new quays at Novo Redondo, Benguela and Loanda, the last being for big ships.

In 1926, 548 ships, of 1,663,706 tonnage, entered the Angolan ports of Benguela, Cabinda, Lobito, Loanda, Noki, Novo Redondo and Amboim. (No figures are available for the ports of Mossamedes, S. Antonio do Zaire, Ambriz and Ambrizete.) The highest figures were: Loanda 94, Lobito 72, Novo Redondo 72, Amboim 67. Of these ships, 386 were Portuguese, 119 German, 8 American, 15 English and 20 of various other nations.

Communications.—In 1927 24,413km. of road were good enough for cars and lorries travelling at 40–50km. per hour, but both they and the rivers are little used. The following railways are open (1927) to traffic: Loanda-Ambaca-Malange (Trans-African railway), of 1m. gauge, begun in 1887, has now 592km. working. It was intended to carry the line across Africa to Mozambique, but when the line reached Ambaca (225m.) in 1894 that scheme was abandoned. The railway, the most expensive in tropical Africa, costing £8,942 per mile, was bought by the Government in 1918. Golungo-Alto railway (gauge .60m.), has 31km. of line in use, the Amboim railway (.60m. gauge), 80 kilometres. The Benguela railway, from Lobito bay, 25m. north of Benguela, begun in 1904, has reached the Belgian frontier, and is to be prolonged 104km. in consequence of the cession of 3,000 sq.km. (Bota de Dilolo) in exchange for 3 sq.km. at the mouth of the Congo river. It is of standard South African gauge (3ft. 6in.), is worked by an English company and has 1,156km. open to traffic; it serves the Katanga copper mines. In consequence of the recent alteration of frontier, a further 104km. of line is to be constructed, bringing the final length up to 1,364km. The Mossamedes railway, running up to the Chela mountains, of .60m. gauge, has 248km. open. Thus the total extent of lines open to traffic is 2,107 kilometres. Lines now under construction are: Loanda-Malange, 50km.; Amboim, 28km.; Benguela, 475km. (which is shortly to be extended); Mossamedes, 67km.

Telegraphic and Telephonic Communication.—Angola is connected by cable with east, west and south African telegraph systems. Land telegraph lines in use extend to 8,528km. including 869 in reconstruction, with 92 stations. Wireless stations are in operation at the chief centres. There are 414 km. of telephone wires, with eight stations, of which only that at Loanda is in good condition.

Industries.—The most important industries at present are palm oil, whale oil, fish oil, resin and derivatives, milling of cereals, preserving fruits, preserving and salting fish, preserving meat. The sugar industry employs 200 Europeans and 9,000 natives, in seven factories near the Dande river, at Catumbela, Bom Jesus, Novo Redondo, Dombe Grande and Quissol; the output is 12,000–15,000 tons per annum. Fishing occupies 2,000 whites and 6,000 natives. There are 120 establishments for catching and preserving fish, employing 500 boats. There is a whaling station at Mossamedes (Porto Amelia). Soap is made in Loanda and Benguela for local use and for export to Belgian Congo and S. Thomé. More than 10,000 tons of salt, mainly to preserve fish, are produced annually. Several factories produce vegetable fibre. Other industries are ceramics, brick and tile-making; carpentry and joinery, practised on a large scale, especially wagon-building; saw-mills; tobacco, with two modern factories in Loanda, local growths being mixed with imported; foundries, the best being that of the State railways.

There is probably a good future before such industries as tanning, production of milk products, lime, paper pulp, rubber products, iron-working, etc. There are several deposits of guano. Ochres, chalks, marbles and lime-stones are known, and would repay working. Ivory and gums are exported.

Agriculture, etc.—There is a Government agricultural museum and experimental station at Loanda, and others in the interior. Hitherto their activities have been limited. The organization of a forestry department has been officially approved, and the woods of Moxico are being exploited. The chief agricultural products are coffee, the principal export, of which four types are grown, the best being that of Novo Redondo (Amboim); maize, the second most important export, grown almost entirely by natives, and chiefly in Benguela and the hinterland of Loanda; palm oil and coconut, grown without much method in the north, a crop with great possibilities on scientific lines; fibre-plants, agaves and furcraias, some plantations having modern machinery; the castor-oil plant grows almost everywhere and there are plantations in Benguela, Libôlo, Amboim, etc.; ground-nuts are grown by natives in many parts of the province; cotton is grown in Mossamedes on a large scale; wheat has done well on the Benguela plateau and in Malange; potatoes, rice, peas, beans and other vegetables are commonly grown on the high lands; the agricultural station at Bié has proved that rye, oats and barley can do well on the high lands, cocoa does well in Cabinda and parts of Amboim; manico is cultivated almost everywhere by natives; bananas thrive everywhere, except in the highest parts of the south; tropical fruits, such as pineapples, guavas and pawpaws, do well almost everywhere; almost all the fruits of Portugal are successfully grown on the high lands; tobacco, of rather inferior quality, is grown a good deal, and could be improved. Sugar-cane is one of the most important products of the province. Some factories have modern machinery. Rubber is found in the interior of Benguela, and is the basis of the present trade with the natives. There are possibilities of the cultivation of flax, especially on the southern plateaux.

Stock-raising.—There is much pasture, and it could be improved; forage can be grown well. The veterinary station at Humpata has achieved good results in the acclimatization of stock, and the improvement of pasture. There is a veterinary mission at Huila. Good cattle, horses and donkeys have been introduced. Sheep and goats do very well, and parts of the highlands have great possibilities. Pigs are second only to cattle in Angola. Crossing of the native pig with foreign strains has given good results. Domestic birds can be acclimatized but native breeds are poor. Ostrich farming has begun. The trade in wax and honey is almost entirely in native hands; but some Europeans are engaging in it successfully. Silk worms have been bred in Huila. The growing of wool is certainly possible on some of the plateaux.

Native Labour.—Recent legislation has improved conditions of recruiting and service. A census of males between 18 and 45 years of age, in 1926, gave, in round numbers, a total of 588,300. The hut-tax list gave the number of men between 16 and 60 as 744,400. The total estimated male population is 1,633,400. Estimates of labour required, probably exaggerated, gave a total of 378,800 as follows: Public Works, 77,200; European agriculture, 101,300; native industries, 24,800; native agriculture, 129,100; various, 46,400. There were available, of men between 18 and 45, 209,500; and between 16 and 60, 365,600, there being a deficit, in native labour available, in the districts of Loanda, Cuanza-Norte and Mossamedes. It is thought that, allowing for evidently exaggerated demands, there is a surplus of 300,000 men fit for work, counting 130,000 for native agriculture. The problem is one of distribution and rational use, made the more difficult by the undesirability of employing men far from their homes. For general necessities there is only one man (of between 16 and 60) to every 1½sq.km. It is necessary, not only to intensify European colonization, but to foster the native population.

HISTORY

The Portuguese established themselves on the west coast of Africa towards the close of the 15th century, the river Congo

and the whole coastline of Angola being discovered by Diogo Cam or Cão in 1482, and the three following years. He erected a stone pillar at the mouth of the river, which accordingly took the title of Rio de Padrão, and established friendly relations with the natives, who reported that the country was subject to a great monarch, Mwani Congo or lord of Congo, resident at Bonza Congo. The Portuguese were not long in making themselves influential in the country. Gonçalo de Sousa was despatched on a formal embassy in 1490; and the first missionaries entered the country in his train. The king was soon after baptized and Christianity was nominally established as the national religion. In 1534 a cathedral was founded at Bonza Congo (renamed São Salvador), and in 1560 the Jesuits arrived with Paulo Diaz de Novaes. Of the prosperity of the country the Portuguese have left the most glowing and indeed incredible accounts. It was, however, about this time ravaged by cannibal invaders (Bangala) from the interior, and Portuguese influence gradually declined. The attention of the Portuguese, moreover, was now turned more particularly to the southern districts of Angola. In 1627 the bishop's seat was removed to São Paulo de Loanda and São Salvador declined in importance: but in the 18th century, in spite of hindrances from Holland and France, steps were taken towards re-establishing Portuguese authority in the northern regions. Until the "scramble for Africa" began in 1884, however, they possessed no settlement on the coast to the north of Ambriz, which was first occupied in 1855; but in 1884-85 they succeeded in securing the southern shores of the estuary of the Congo (see CONGO FREE STATE). The last of the native princes of Congo who had real authority was a potentate known as Dom Pedro V. He was placed on the throne in 1855 with the help of a Portuguese force, and reigned over 30 years. In 1888 a Portuguese resident was stationed at Salvador, and the kings of Congo became pensioners of the government.

BY COURTESY OF THE PHELPS-STOKES FUND
A CHIEF OF ANGOLA
Although chiefs still rule the native tribes, their administration is supervised by the Portuguese Government

The first governor sent to Angola was Paulo Diaz, a grandson of Bartholomew Diaz, who reduced to submission the region south of the Kwanza nearly as far as Benguela. The city of Loanda was founded in 1576, Benguela in 1617. From that date the sovereignty of Portugal over the coastline, from its present southern limit as far north as Ambriz (7° 50' S.) has been undisputed save between 1640 and 1648, during which time the Dutch attempted to expel the Portuguese and held possession of the ports. Whilst the economic development of the country was not entirely neglected and many useful food products were introduced, the prosperity of the province was very largely dependent on the slave trade with Brazil, which was not legally abolished until 1830 and in fact continued for many years subsequently.

Agreements concluded with the Congo Free State, Germany and France in 1885-86 (modified in details by subsequent arrangements) fixed the limits of the province, except in the south-east, where the frontier between Barotseland (north-west Rhodesia) and Angola was determined by an Anglo-Portuguese agreement of 1891 and the arbitration award of the king of Italy in 1905 (see AFRICA: History). Up to the end of the 19th century the hold of Portugal over the interior of the province was slight, though its influence extended to the Congo and Zambezi basins. The abolition of the external slave trade proved very injurious to the trade of the seaports, but from 1860 onward the agricultural resources of the country were developed with increasing energy, a work in which Brazilian merchants took the lead. After the definite partition of Africa among the European powers, Portugal applied herself with some seriousness to exploit Angola and her other African possessions. Nevertheless, in comparison with its natural wealth the development of the country has been slow. Slavery and the slave trade continued to flourish in the interior in the

early years of the 20th century, despite the prohibitions of the Portuguese Government. The extension of authority over the inland tribes proceeded very slowly and was not accomplished without occasional reverses.

A measure granting Angola a degree of autonomy was passed by the Portuguese parliament in 1914, followed in 1920 by a more liberal measure. In 1920, also, Gen. Norton de Mattos, a former governor, returned to Angola as High Commissioner with an ambitious programme of development and colonization. Chief attention was to be paid to harbour improvements and railways, the deficiency of means of communication being a leading cause of the backward state of the country. For two years there was much activity, but then a crisis arose, due in part to the lack of sufficient produce for export to pay for the imports of the Government and the trading community, and in part to the inability of Angola to raise more than about a sixth of the authorised loan of 60,000 gold contos (about £13,300,000). The crisis was acute throughout 1924. In 1925 the Portuguese Government voted 9,000 gold contos (£2,000,000) to enable the colony to carry out the most needed public works. These included the reconstruction of the Loanda railway, which had been bought by the state in 1918 and serves valuable coffee areas. Apart from the cost of development works, public expenditure frequently exceeded revenue. Between 1910 and 1925 the revenue increased from about £500,000 a year to over £1,000,000.

A Native Affairs Department was created in 1913 and it effected various reforms, but the principle of compulsory labour was maintained. From 1918 to 1921 the authorities took an active part in the recruitment of labour for private enterprise. The system led to abuses and was abolished in 1921. Continued complaints that labour was not procurable resulted, however, in 1925, in a partial return to the old system, chiefs being required to produce the men and both chiefs and officials receiving payment per head for the labour obtained.

The Benguela railway, a British enterprise, which starts at Lobito Bay, was intended primarily to serve the copper fields of Katanga, Belgian Congo, but in crossing the plateau of southern Angola it opened up the territory best suited to European settlement. (See above "Communications.") By an agreement made with Belgium in 1927, a small part of the Belgian Congo on the Upper Kasai basin was transferred to Angola, the effect being to lengthen the Benguela railway by 40 miles. The junction with the Congo line was fixed at the Luao river. In 1928 the Portuguese determined to make Huambo, a town on the Benguela railway and finely situated on the plateau, the capital of the province.

Germany had for many years looked upon Angola as a field of economic and ultimately political penetration, and a treaty with Great Britain negotiated in 1913-14 recognized German economic interests as supreme in the greater part of Angola. The outbreak of the World War prevented the signature of this treaty, while the loss of South-west Africa, conquered by General Botha in 1915, deprived Germany of a base for penetration. Nevertheless after the war German influence and trade within the colony steadily grew, so that by 1925 Germans exceeded in number all other European residents combined, with the exception of the Portuguese.

ANGOLA, a conventional trade term used to describe a particular type of "union" or "mixture" yarn produced from short staple or "shoddy" wool and raw staple cotton, blended together by a "scribbling" process to ensure their thorough admixture, before spinning. The wool and cotton are blended in varying proportions chiefly according to the particular class of fabric for which it is intended, and the peculiar characteristics of texture, such as the "handle" or "feel" and other features that may be desired in the finished fabric. A typical and recognized standard quality of angola yarn is produced from wool and cotton blended in the proportion of 80% wool and 20% cotton.

The admixture of cotton with the short staple "shoddy" wool not only improves the spinning properties of the latter and thus enables yarn of finer counts to be spun than would be possible from the short fibres of wool themselves, but the cotton staple also serves to impart to the yarn a soft and mellow "feel," which is one of the distinctive characteristics of Angola fabrics.

Angola yarn is manufactured into quite a large variety of textile fabrics, both knitted and woven, in each of which classes of goods it may be employed either alone or in combination with yarns produced from any other class of textile fibre, as cotton, silk, artificial silk, and worsted yarns. In the production of certain types of warp-faced worsted fabrics, as exemplified in amazon, covert coating, venetian, and similar varieties, angola yarn is sometimes employed for the weft series of threads which, in fabrics of this class, lies entirely obscured at the back of the cloth and is not, therefore, exposed to wear and tear.

Angola yarn, however, is chiefly employed alone both as warp and weft in the production of so-called "union" fabrics, usually of some simple weave structure as the plain calico or "tabby" weave; a regular twill weave such as the 3-end or 4-end (2×2) twill; the 2×2 matt or dice, or similar elementary structure. Fabrics of this class are made up into garments for underwear, as undershirts and shirts, also for night attire, as pyjamas, night-dresses and dressing gowns.

It should be noted that the term angola is not synonymous with angora, the name of a famous breed of goats that yield a valuable fleece of wool known as "mohair." (H. N.)

ANGONI. The name, an appellation bestowed by the Bantu immediately north of them, is recognized by the Angoni as their own, and they are also known as Tuta, Gwangwara, Zitu and Fiti according to their geographical position. The Angoni, now a ruling caste rather than a distinct race, were originally a Zulu clan which was expelled by Chaka in the 19th century. Under Zwangendaba they marched northwards, incorporating with themselves Swazi and Thonga and elements of other tribes whom they victoriously traversed. During their progress they dropped colonies which have become incorporated into the neighbouring tribes. Thus the Anyanja absorbed a section known as Chekusi's men, which broke off and settled near Chindundo, south-west of Lake Nyasa. The main body, however, passed northward and reached Ufipa at the south-east corner of Lake Tanganyika, where they remained till the death of Zwangendaba in the late '40s.

The Angoni live partly in scattered homesteads, partly in villages. These are neither fenced nor fortified except in the case of a few chiefs. Quite often the village consists only of a man, his wives and children and his slaves, but a chief would naturally be surrounded by a larger following, whose huts are usually grouped in a circle round the enclosure containing the chief's hut. The huts are conical with a pointed roof, often 30 ft. in height, fully covering the substructure, a 5-ft. wall of poles and clay. It is thatched with thick bundles of grass supported by converging poles. The diameter varies but may reach 38 ft., though it is usually considerably smaller. Almost certainly the huts are indigenous and not Zulu, as they are similar to those of their neighbours and their size and structure are doubtless conditioned by the local materials. Their weapons are of the Zulu pattern: a heavy thrusting spear, a few throwing spears, a large oval shield of unframed ox-hide and a club or a battle axe.

Polygyny prevails, each wife owning a separate hut, and the number of wives is only limited by a man's means and ability to pay the dowry. The clans are exogamous and patrilineal, but

the family of the mother must be of distinguished blood when it is a question of the succession to the chieftainship.

The political organization varies with the different groups according to the degree to which the Angoni have imposed themselves on the indigenous population. The chief rules as a military autocrat, but his power is limited by his indunas or military chiefs. Those near him will be kept under control, whereas the outliers may become almost independent. The military organization is based on the Zulu model, for all freemen are liable to service, enrolled in regiments, constantly disciplined and kept in garrisons. They are under the command of indunas, who form a military and civil council to the chief. As among the Zulu, the regiments are not allowed to marry until given permission to do so by the chief.

Their religious system includes a deity *Mulungu*, the director or governor of the earth, and the worship of dead ancestors (*mahoka*), who are more intimately concerned with the affairs of men. The soul is indestructible and sacrifices are made at the graves of the dead to propitiate even more than to supplicate the ancestral spirits. The nature of *mulungu* is not quite clear, but as it is applied also to the spirits of the dead and as local deities seem to be in many instances identical with deceased chiefs it is probable that *mulungu* is the great impersonal spirit of all men who are dead.

ANGORA or ANKARA. (1) The capital of Turkey (anc. ANCYRA), situated upon a steep, rocky hill, which rises 500 ft. above the plain, on the left bank of the Enguri Su, a tributary of the Sakaria (Sangarius), about 220 m. E.S.E. of Constantinople. The hill is crowned by the ruins of the old citadel, which add to the picturesqueness of the view; but the town is not well built, its streets being narrow and many of its houses constructed of sun-dried mud bricks; there are, however, many fine remains of Graeco-Roman and Byzantine architecture, the most remarkable being the temple of Rome and Augustus, on the walls of which is the famous *Monumentum Ancyranum* (see ANCYRA). Ancyra was the centre of the Tectosages, one of the three Gaulish tribes which settled in Galatia in the 3rd century B.C., and became the capital of the Roman province of Galatia when it was formally constituted in 25 B.C. During the Byzantine period, throughout which it occupied a position of great importance, it was captured by Persians and Arabs; then it fell into the hands of the Seljuk Turks, was held for 18 years by the Latin Crusaders, and finally passed to the Ottoman Turks in 1360. In 1402 a great battle was fought in the vicinity of Angora, in which the Turkish sultan Bayezid was defeated and made prisoner by the Tatar conqueror Timur. In 1415 it was recovered by the Turks under Mohammed I., and since that period has belonged to the Ottoman empire. In 1832 it was taken by the Egyptians under Ibrahim Pasha. Angora exports wool, mohair and grain. Mohair cloth is manufactured, and the town is noted for its honey and fruit. Pop. (1927), 107,641.

The Turkish Nationalist Movement, which was organized by Mustafa Kemal in 1919, led to the setting up of a Nationalist Government at Angora in April 1920, the city being chosen owing to the fact that, while it was far enough from the coast to be reasonably safe from attack by the Greeks, or the principal Allied Powers, it was in touch with other parts of the interior of Anatolia, and was the railhead of the north-eastern branch of the Anatolian railway. The ability of the surrounding area to supply the food requirements of the population and the raw materials needed by local industry was also of importance. On Oct. 13, 1923, by a decision of the Great National Assembly, Angora was declared the capital of Turkey.

The city is connected by the Anatolian railway with Constantinople, and a line to Sivas had reached Kaisarieh in 1927. In view of its increased importance and growing population, Angora is badly equipped as regards accommodation for its population and for the Government, and as regards sanitary arrangements, etc. Considerable progress has, however, been made by the municipi-

pality in house building, road construction and sanitation. A beginning was made with the drainage of the swampy fields between the station and the town, a breeding ground for the malarial mosquito, and with the construction of a public park; modern systems of drainage and of water supply were commenced. A new parliament house and buildings for the Ministry of Finance, Courts of Justice, General Post Office, etc., and a modern hotel have been built. The industrial development of the city is being actively encouraged, and German engineers have been called in to erect factories and workshops for the production of tiles, cotton and flax goods, etc. The installation of a power station capable of furnishing electric light throughout the city has been completed, sawmills constructed, and a flourmill equipped with modern machinery. The Government decided in 1925 to install a telephone exchange and erect a powerful wireless station. By the end of 1925 certain foreign legations had moved their headquarters from Constantinople to Angora, and the others were represented by secretaries.

(2) A Turkish vilayet in north-central Asia Minor, which includes most of the ancient Galatia (pop. [1927], 404,726). It is an agricultural country, depending for its prosperity on its grain, wool and mohair obtained from the beautiful Angora goats. It includes the city of Angora.

See C. Ritter, *Erkunde von Asien*, vol. xviii. (1837-39); V. Cuinet, *La Turquie d'Asie* (1891); Murray's *Handbook to Asia Minor* (1895); and other works mentioned under ANCYRA.

ANGOSTURA BARK, the bark of *Cusparia febrifuga*, is used in the form of an extract as an astringent to increase the appetite, to stimulate gastric secretion and as a tonic. Its effect, best obtained by administration a few minutes before meals, is due to the bitter alkaloid cusparine. Its action is probably a reflex one between the taste buds and the gastric glands. Angostura bark is now very seldom prescribed.

ANGOULÊME, CHARLES DE VALOIS, DUKE OF (1573-1650), natural son of Charles IX. of France by Marie Touchet, was born at Fayet, Dauphiné, April 28 1573. His mother married François de Balzac, Marquis d'Entraignes, and one of her daughters, Henriette, marquise de Verneuil, afterwards became the mistress of Henry IV. Charles, known in his early manhood as Comte d'Auvergne, was made colonel of horse by Henry IV., and served in the campaigns of Arques and Ivry. But in 1601 he was implicated in the Biron conspiracy, one of the objects of which was to persuade Henry to repudiate his wife. Biron was executed, but Auvergne, after making a full confession, was released. He then engaged in fresh intrigues with the Spanish court, acting in concert with his half sister, the king's mistress, and her father. Henriette was pardoned, but Auvergne spent 11 years in the Bastille. On his release in 1616 he was reinstated in the army, and employed in several campaigns. He became Duke of Angoulême in 1619. He commanded at the siege of La Rochelle in 1627, and in Lorraine in 1635. He retired soon after Richelieu's death in 1643, and lived in retirement until Sept. 24 1650.

The duke was the author of the following works: (1) *Mémoires*, from the assassination of Henri III. to the battle of Arques (1589-93), published at Paris by Boneau, and reprinted by Buchon in his *Choix de chroniques* (1836) and by Petitot in his *Mémoires* (1st series, vol. xiv.); (2) *Les Harangues, prononcées en assemblée de MM. les princes protestants d'Allemagne*, par Monseigneur le duc d'Angoulême (1620); (3) a translation of a Spanish work by Diego de Torres. To him has also been ascribed the work *La générale et fidèle Relation de tout ce qui s'est passé en l'isle de Ré, envoyée par le roi à la royne sa mère* (Paris, 1627).

ANGOULÊME, LOUIS-ANTOINE DE BOURBON, DUKE OF (1775-1844), the last dauphin of France, elder son of the count of Artois (afterwards Charles X.) and of Marie-Thérèse of Savoy, was born in Versailles on Aug. 6, 1775, and died in Goritz, in Austria, on June 3, 1844. In 1789 he left France with his father and, after completing his military training at Turin, commanded a corps of émigrés in the campaign of 1792. After residing in Poland and in England he returned to France in 1814, took possession of Bordeaux, and, as lieutenant-general, organized a futile attempt to resist Napoleon on the latter's return from Elba, after which Angoulême was captured and transported to Barce-

lona. In Louis XVIII.'s reign he commanded the French expedition to Spain in support of Ferdinand VII. (1823); on the accession of Charles X. the duke of Angoulême became dauphin, but in 1830, with his father, he renounced his claim to the throne, and finally settled in Austria, at Goritz, under the title of count of Marne, until his death.

In 1799 he had married his cousin MARIE-THÉRÈSE CHARLOTTE, the daughter of Louis XVI. and Marie Antoinette, who was born at Versailles on Dec. 19, 1778, and died at Frohsdorf on Oct. 19, 1851. During the Revolution she was imprisoned for three years, from Aug. 1792 until 1795, when she was released in exchange for prisoners handed over to the Convention by Dumouriez. In 1814 she returned to France in the train of Louis XVIII., and for ten days after Napoleon had entered the Tuileries during the Hundred Days, she was able to maintain Bordeaux's loyalty to the royal family.

ANGOULÊME, south-west France, capital of the department of Charente, 83m. N.N.E. of Bordeaux on the railway from Poitiers. Pop. (1926) 32,002. The old town is on a small steep-sided peninsula washed on the north by the Charente, and on the south and west by a small tributary, the Anguienne. The more important suburbs lie towards the east where the promontory joins the surrounding plateau. The main railway line passes through a tunnel beneath the town.

Angoulême (*Iculisma*) was taken by Clovis from the Visigoths in 507, and plundered by the Normans in the 9th century.

In 1360 it was surrendered by the peace of Bretigny to the English; they were, however, expelled in 1373 by Charles V., who granted the town numerous privileges. It suffered during the Wars of Religion, especially in 1568 after its capture by Protestants under Coligny.

The countship of Angoulême dated from the 9th century, the most important of the early counts being William Taillefer, whose descendants held the title till the end of the 12th century. After a short period of possession by King John of England it passed by marriage, in 1220, to the Lusignan family, counts of Marche. In 1394 the countship came to the house of Orléans, a member of which, Francis I., became king of France in 1515 and raised it to the rank of duchy. The duchy afterwards changed hands several times, one of its holders being Charles of Valois, natural son of Charles IX. The last duke was Louis-Antoine, eldest son of Charles X., who died in 1844.

Angoulême is encircled by boulevards, which, as in so many French towns, are altered ramparts. The cathedral of St. Pierre, a church in the Byzantine Romanesque style (*cf.* Périgueux), dates from the 11th and 12th centuries, but has been often restored. The façade, flanked by two towers with cupolas, is highly decorated. The crossing is surmounted by a dome, and the extremity of the north transept by a fine square tower over 160ft. high. The domed style in this district is a characteristic feature. The *hôtel de ville*, by Abadie, is modern but preserves two towers of the *château* of the counts. Angoulême is the seat of a bishop, a prefect, and court of assizes. Its public institutions include tribunals of first instance and of commerce, a council of trade-arbitrators and chamber of commerce. It also has a library and several learned societies. It is the centre of an old-established paper-making industry. Most of the mills are situated on water-courses near the town. Subsidiary industries, such as those of small machinery and wire fabrics, are numerous. Commerce is carried on in wine and brandy.

ANGOUMOIS, an old province of France, nearly corresponding to-day to the department of Charente. Its capital was Angoulême.

ANGRA or ANGRA DO HEROISMO ("Bay of Heroism," a name given it in 1829, to commemorate its successful defence against the Miguelist party), the former capital of the Azores (Portuguese), and chief town of an administrative district, comprising the islands of Terceira (on which it lies), St. George and Graciosa. Pop. (1920) 10,057. It is the headquarters of a military command and the see of a Roman Catholic bishop; its principal buildings are the cathedral, military college, arsenal and observatory. The harbour, formerly a naval station, is shel-

tered by the promontory of Mt. Brazil. Pineapples and other fruit are exported.

ANGRA PEQUENA: see LÜDERITZ.

ÅNGSTRÖM, ANDERS JONAS (1814–1874), Swedish physicist, was born on Aug. 13, 1814, at Lögö, Medelpad, Sweden. He was educated at Uppsala university, where in 1839 he became *Privatdozent* in physics. In 1843 he became observer at Uppsala Observatory. In 1858 he succeeded Adolph Ferdinand Svanberg (1806–1857) in the chair of physics at Uppsala, and there he died on June 21, 1874. His most important work was concerned with the conduction of heat and with spectroscopy. In his optical research *Optiska Undersökningar*, presented to the Stockholm Academy in 1853, he not only pointed out that the electric spark yields two superposed spectra, one from the metal of the electrode and the other from the gas in which it passes, but deduced from Euler's theory of resonance that an incandescent gas emits luminous rays of the same refrangibility as those which it can absorb. This statement entitles him to rank as one of the founders of spectroscopy. The Ångström unit was named in his honour.

From 1861 onwards he paid special attention to the solar spectrum. He announced in 1862 the existence of hydrogen, among other elements, in the sun's atmosphere, and in 1868 published his great map of the normal solar spectrum, which long remained authoritative in questions of wave-length although his measurements were inexact to the extent of one part in 7,000 or 8,000, the metre which he used as his standard having been slightly too short. He was the first, in 1867, to examine the spectrum of the aurora borealis and to detect and measure the characteristic bright line in its yellow green region; but he was mistaken in supposing that this same line, which is often called by his name, is also to be seen in the zodiacal light.

His son **KNUT JOHAN ÅNGSTRÖM** (1857–1910) became professor of physics at Uppsala in 1896. He investigated the radiation of heat from the sun and its absorption by the earth's atmosphere and devised various delicate methods and instruments, including his electric compensation pyrheliometer, invented in 1893, and apparatus for obtaining a photographic representation of the infra-red spectrum (1895).

ÅNGSTRÖM UNIT, the unit employed for measuring wavelengths of light, being equal to one ten-millionth of a millimetre, i.e., 1×10^{-10} metre. The usual abbreviation for this unit is Å.U. (See SPECTROSCOPY.)

ANGUIER, FRANÇOIS (c. 1604–1669) and **MICHEL** (1612–1686), French sculptors, were two brothers, natives of Eu in Normandy. The mausoleum of Henri II., last duc de Montmorancy, at Moulins, is the work of François. To Michel are due the sculptures of the triumphal arch at the Porte St. Denis, begun in 1674, to serve as a memorial for the conquests of Louis XIV. A marble group of the Nativity in the church of Val De Grâce was reckoned his masterpiece. It was he who superintended the decoration of the apartments of Anne of Austria in the old Louvre. F. Fouquet also employed him for his château in Vaux.

See Henri Stein, *Les frères Anguier* (1889), with catalogue of works and many references to original sources; Armand Sanson, *Deux Sculpteurs Normands; les frères Anguier* (1889).

ANGUILLA or Snake Island, British West Indies, part of the presidency of St. Kitts-Nevis, in the colony of the Leeward Islands, 18° 12' N. and 63° 5' W., about 60m. N.W. of St. Kitts, 16m. long, area 35sq.m., population estimated 4,398, mostly negroes. Charcoal-burners have almost completely denuded the island, which having but little rain is very subject to drought. Nearly all the land is in the hands of peasant proprietors, who cultivate cotton, sweet potatoes, peas, beans, corn, etc., and rear sheep and goats. Cotton, cattle, phosphate of lime and salt are the principal exports.

ANGULATE, shaped with corners or angles; used in botany and zoology for the shape of stems, leaves and wings.

ANGUS, EARLS OF. Angus is the official name of the former county of Forfarshire (*q.v.*), and was that of one of the original earldoms of Pictish, Scotland, said to have been occupied by seven brothers of whom Angus was the eldest. The Celtic line ended with Matilda (c. 1240), countess of Angus in

her own right, who married in 1243 Gilbert de Umfravill and founded the Norman line of three earls, which ended in 1381, the then holder of the title being summoned to the English parliament. Meanwhile John Stewart of Bonkyl, Co. Berwick, had been created earl of Angus in a new line. This third creation ended with Margaret Stewart, countess of Angus in her own right, and widow of Thomas, 13th earl of Mar. By an irregular connection with William, 1st earl of Douglas, who had married Mar's sister, she became the mother of George Douglas, 1st earl of Angus (c. 1380–1403), and secured a charter of her estates for her son, to whom in 1389 the title was granted by King Robert II. He was taken prisoner at Homildon Hill and died in England.

His great-grandson was **ARCHIBALD DOUGLAS** (c. 1450–c. 1514), 5th earl, known as the *Great Earl* and nicknamed *Bell-the-Cut* for his capture of Robert Cochrane, earl of Mar, the favourite of James III. He joined Alexander Stewart, earl of Albany, in intriguing with Edward IV., acknowledged the overlordship of the English Crown and was one of the leaders of the rebellion against James III. in 1487–88. He renewed his English intrigues under the reign of James IV., but was in favour with the court between 1493 and 1498 and became chancellor of the kingdom. At Flodden Field he lost two of his sons. His third son, Gavin, bishop of Dunkeld, is separately noticed.

ARCHIBALD DOUGLAS (1489?–1557), 6th earl, son of George, master of Douglas, who was killed at Flodden, succeeded on his grandfather's death. By his marriage in 1514 to his second wife, the queen dowager, Margaret of Scotland, sister of Henry VIII., he aroused the jealousy of the nobles. In the civil war which followed, Albany (the regent) besieged the queen in Stirling and obtained possession of the young king, Margaret's son. Margaret left for London, and Angus made his peace with Albany. During his wife's absence he formed a liaison with a daughter of the laird of Traquair. When Margaret returned she therefore sided with Albany against her husband. Angus was charged with high treason and sent to France in 1522. He returned two years later with the support of Henry VIII., entered Edinburgh in 1525, and called a parliament. After a short struggle he and the Douglasses became all powerful. James V. did not like his stepfather's tutelage, but all attempts at that time to secure his liberation failed. In 1528 Margaret obtained a divorce from her husband, James escaped from his custody and took refuge with Margaret and Arran at Stirling. The next year Angus took refuge in England, and James avenged himself on his kinsmen, including Angus's sister Janet, Lady Glamis, who was burned at the stake on Castle hill, Edinburgh (July 17 1537). It was only in 1542, after the death of James V., that Angus returned to Scotland, entrusted with a mission to arrange a marriage between Mary queen of Scots and Prince Edward (afterwards Edward VI.). The marauding expedition of Lord Hertford in 1544 seems to have cured him of his English sympathies, and he was made lieutenant of the south of Scotland. On Feb. 27 1545 he defeated the English at Ancrum moor, and he led the Scottish van when the Scots were defeated at Pinkie.

The career of Angus was a long struggle for power and for the interests of his family, to which national considerations were completely subordinate. He died in Jan. 1557. By Margaret Tudor he had Margaret, his only surviving legitimate child, who married Matthew, 4th earl of Lennox, and was mother of Lord Darnley. He was succeeded by his nephew David, son of Sir George Douglas of Pittendreich.

ARCHIBALD DOUGLAS (1555–1588), 8th earl, and earl of Morton, was the son of David, 7th earl. He succeeded to the title and estates in 1558. In 1573 he was made a privy councillor and sheriff of Berwick, in 1574 lieutenant-general of Scotland, in 1577 warden of the west marches and steward of Fife, and in 1578 lieutenant-general of the realm. For his support of his uncle, the 4th earl of Morton, he was declared guilty of high treason on June 2 1581. He appealed to the English Government for an invasion of Scotland to rescue Morton, and on the latter's execution in June went to London, where he was welcomed by Elizabeth. After the raid of Ruthven in 1582 Angus was reconciled to James, but soon afterwards was again banished from

the court. In 1584 he joined the rebellion of Mar and Glamis, but the movement failed. The rebels fled to Newcastle, which became a centre of Presbyterianism and of projects against the Scottish Government, encouraged by Elizabeth. In October they invaded Scotland and secured from James the restoration of their estates and the control of the Government. In 1586 Angus was appointed warden of the marches and lieutenant-general on the border, but he was unable to overcome the king's hostility to the establishment of Presbyterian government. He died on Aug. 4 1588.

He was succeeded in the earldom by his cousin WILLIAM, who was succeeded by his son William. On a visit to France he was converted to Roman Catholicism, and on his return to Scotland became involved in various conspiracies against the Government, being twice imprisoned. In 1593 he joined the rebellion of the earls of Huntly and Erroll. The revolt failed, and in 1597 all three renounced their religion, declared themselves Presbyterians, and were restored to the lands and honours they had forfeited. Angus recanted in 1608 and withdrew to France; he died in Paris on March 3 1611. He was succeeded by his son William (1589-1660), 11th earl, afterwards 1st marquess of Douglas. The title is now held by the dukes of Hamilton.

ANGUSSOLA or **ANGUSSCIOLA, SOPHONISBA**, Italian portrait painter of the latter half of the 16th century, was born at Cremona about 1535, and died at Palermo in 1626. In 1560, at the invitation of Philip II., she visited the court of Madrid, where her portraits elicited high praise. Vandyck is said to have declared that he had derived much knowledge of the true principles of his art from her conversation. She painted several fine portraits of herself, one of which is at the Uffizi. A few specimens of her painting are to be seen at Berlin, Milan, Rome, Bergamo, Madrid and in private collections in England. She had three sisters who were also celebrated artists.

ANHALT, a free State of Germany, with constitution dated July 18, 1919. The former duchy was created in 1863 by amalgamation of two duchies, Anhalt-Dessau-Cöthen and Anhalt-Bernburg, and comprised all the Anhalt territories sundered in

Western Anhalt is much smaller and its southern half forms part of the Harz range, reaching to nearly 2,000ft. in the south-east. Of the whole surface, land under tillage amounts to about 60%, meadowland to 7% and forest to 25%. The chief crops are grain (especially wheat), fruit, vegetables, potatoes, beet, tobacco, flax, linseed and hops. The country is very rich in lignite, and salt works are abundant. The chief industrial products are sugar spirits, beer and chemicals, and there is commerce in corn, cattle, timber and wool. Coal (lignite), guano, oil and bricks are also exported. The trade of the country is furthered by its excellent roads, navigable rivers and railways. There is a chamber of commerce in Dessau. The area of Anhalt is 888sq.m. with a population of 351,471 in 1925. The country is divided into the districts of Dessau, Cöthen, Zerbst, Bernburg and Ballenstedt. The chief towns are Dessau, the capital (70,241), Bernburg (34,178), Cöthen (26,588), Zerbst (19,229) and Rosslau (12,306). The inhabitants of the State are mainly Protestant, organized under the consistory in Dessau. The Roman Catholics are under the bishop of Paderborn. Since 1922 there has been an Assembly, with executive power in the hands of a Ministry of State, under the presidency of the prime minister, with whom are associated one or two other ministers.

History.—During the 11th century most of Anhalt was included in the duchy of Saxony, and in the 12th century it came under the rule of Albert the Bear, margrave of Brandenburg. When Albert died in 1170, his son Bernard, who received the title of duke of Saxony in 1180, became count of Anhalt. Bernard died in 1212, and Anhalt, separated from Saxony, passed to his son Henry, who in 1218 took the title of prince and was the real founder of the house of Anhalt. On Henry's death in 1252 his three sons partitioned the principality and founded respectively the lines of Aschersleben, Bernburg and Zerbst. Early in the 16th century, however, owing to the death or abdication of several princes, the family had become narrowed down to the two branches of Anhalt-Cöthen and Anhalt-Dessau. These were united temporarily in 1570, but Anhalt was divided again in 1603.

The family of Anhalt-Cöthen became extinct in 1847, and Cöthen was added to Anhalt-Dessau. In 1863, for the same reason, Anhalt-Bernburg was united with Anhalt-Dessau.

Anhalt-Dessau had been divided in 1632, but was quickly reunited; and in 1693 it came under the rule of Leopold I. (see ANHALT-DESSAU, LEOPOLD I., PRINCE OF). Leopold IV. (reigned 1817-71) in 1863 reunited the whole of Anhalt. He took the title of duke of Anhalt and summoned one *Landtag* for the whole of the duchy. In 1871 Anhalt became a state of the German empire. In 1918, in common with the rest of Germany, it threw off its allegiance to the emperor, and on July 18, 1919, received its constitution as the Free State of Anhalt.

ANHALT-DESSAU, LEOPOLD I., PRINCE OF (1676-1747), called the "Old Dessauer" (Der alte Dessauer), general field marshal in the Prussian army, was the only surviving son of John George II., prince of Anhalt-Dessau, and was born on July 3, 1676, at Dessau. His first campaign was that of 1695 in the Netherlands, in which he was present at the siege of Namur. He remained in the field to the end of the war of 1697, the affairs of the principality being managed chiefly by his mother, Princess Henriette Catherine of Orange. In 1698 he married Anna Luise Föse, an apothecary's daughter, of Dessau, in spite of his mother's opposition, and subsequently he procured for her the rank of a princess from the emperor (1701). The princess acquired an influence over the stern nature of her husband which she never ceased to exert on behalf of his subjects, and after the death of Leopold's mother she performed the duties of regent when he was absent on campaign. Often, too, she accompanied him into the field. Leopold's career as a soldier in important commands begins with the outbreak of the War of the Spanish Succession. He had made many improvements in the Prussian army, notably the introduction of the iron ramrod about 1700, and he then took the field at the head of a Prussian corps on the Rhine, serving at the sieges of Kaiserswerth and Venlo. Leopold was present at Höchstädt, Blenheim, Cassano, Turin, Tournay, and Malplaquet, and in 1710 he succeeded to the command of the

BY COURTESY OF THE GERMAN RAILWAY INFORMATION BUREAU
OLD TOWN WALL GATE OR "HEIDETOR," AT ZERBST IN THE DUCHY OF ANHALT, A PART OF THE MEDIAEVAL FORTIFICATIONS ROUND THE CITY

1603. It now consists of two larger portions—eastern and western Anhalt, separated by part of Prussian Saxony—and of five enclaves surrounded by Prussian territory, viz., Alsleben, Mühlungen, Dornburg, Gödnitz and Tilkerode-Abberode. The eastern and larger portion of the State is low-lying, and occupies a section of the sandy plains of the valley of the Elbe which crosses it from east to west, and portions of the tributary valleys of Mulde and Saale, flowing northwards. There is fertile loess land east of the Saale, but the State contains much pine forest and bog land, interspersed with rich pasture.

whole Prussian contingent at the front. In 1712, at the particular desire of the crown prince, Frederick William, who had served with him as a volunteer, he was made a general field marshal. Shortly before this he had executed a *coup de main* on the castle of Mörs, which was held by the Dutch in defiance of the claims of the king of Prussia. The operation was effected with absolute precision and the castle was seized without a shot being fired. In the earlier part of the reign of Frederick William I., the prince of Dessau was one of the most influential members of the Prussian governing circle. In the war with Sweden (1715) he commanded an army of 40,000 men, and met and defeated Charles XII. in a severe battle on the island of Rügen (Nov. 16). His conduct of the siege of Stralsund which followed was equally skilful, and the great results of the war to Prussia were largely to be attributed to his leadership in the campaign.

In the years of peace he devoted himself to the training of the Prussian army. The reputation it had gained in the wars of 1675 to 1715, though good, gave no hint of its coming glory, and it was even in 1740 accounted one of the minor armies of Europe. That it proved, when put to the test, to be by far the best military force existing may be taken as the summary result of Leopold's work. The "Old Dessauer" was one of the sternest disciplinarians in an age of stern discipline, and the technical training of the infantry, under his hand, made them superior to all others in the proportion of five to three. He was essentially an infantry soldier—in his time artillery did not decide battles—but he suffered the cavalry service, in which he felt little interest, to be comparatively neglected, with results which appeared at Mollwitz. Frederick the Great formed the cavalry of Hohenfriedberg and Leuthen himself, but had it not been for the incomparable infantry trained by the "Old Dessauer" he would never have had the opportunity of doing so. Thus Leopold, heartily supported by Frederick William, who was himself called the great drill-master of Europe, turned to good account the 20 years following the peace with Sweden. Two incidents of that period in his career call for special mention: first, his intervention in the case of the crown prince Frederick, who was condemned to death for desertion, and his continued and finally successful efforts to secure Frederick's reinstatement in the Prussian army; and secondly, his part in the War of the Polish Succession on the Rhine, where he served under his old chief Eugene and held the office of field marshal of the Empire.

With the death of Frederick William in 1740, Frederick succeeded to the Prussian throne, and a few months later took place the invasion and conquest of Silesia, the first act in the long Silesian wars and the test of the work of the "Old Dessauer's" lifetime. The prince himself was not often employed in the king's own army, though his sons held high commands under Frederick. The king, indeed, found Leopold, who was reputed, since the death of Eugene, the greatest of living soldiers, somewhat difficult to manage, and the prince spent most of the campaigning years up to 1745 in command of an army of observation on the Saxon frontier. Early in that year his wife died. He was then over 70, but his last campaign was destined to be the most brilliant of his long career. A combined effort of the Austrians and Saxons to retrieve the disasters of the summer by a winter campaign towards Berlin itself led to a hurried concentration of the Prussians. Frederick from Silesia checked the Austrian main army and hastened towards Dresden. But before he had arrived, Leopold, no longer in observation, had decided the war by his overwhelming victory of Kesselsdorf (Dec. 14 1745). It was his habit to pray before battle, for he was a devout Lutheran. On this last field his words were, "O Lord God, let me not be disgraced in my old days. Or if Thou wilt not help me, do not help these scoundrels, but leave us to try it ourselves." With this great victory Leopold's career ended. He retired from active service, and the short remainder of his life was spent at Dessau, where he died on April 7, 1747.

He was succeeded by his son, LEOPOLD II., MAXIMILIAN, PRINCE OF ANHALT-DESSAU (1700–51), who was one of the best of Frederick's subordinate generals, and especially distinguished himself by the capture of Glogau in 1741, and his generalship at

Mollwitz, Chotusitz (where he was made general field marshal on the field of battle), Hohenfriedberg and Soor.

Another son, PRINCE DIETRICH OF ANHALT-DESSAU (d. 1769), was also a distinguished Prussian general.

But the most famous of the sons was PRINCE MORITZ OF ANHALT-DESSAU (1712–60), who entered the Prussian army in 1725, saw his first service as a volunteer in the War of the Polish Succession (1734–35), and in the latter years of the reign of Frederick William held important commands. In the Silesian wars of Frederick II., Moritz greatly distinguished himself, especially at the battle of Hohenfriedberg (Striegau), 1745. At Kesselsdorf it was the wing led by the young Prince Moritz that carried the Austrian lines and won the "Old Dessauer's" last fight. In the years of peace preceding the Seven Years' War, Moritz was employed by Frederick the Great in the colonizing of the waste lands of Pomerania and the Oder Valley. When the king took the field again in 1756, Moritz was in command of one of the columns which hemmed in the Saxon army in the lines of Pirna, and he received the surrender of Rutowski's force after the failure of the Austrian attempts at relief. Next year Moritz underwent changes of fortune. At the battle of Kolin he led the left wing, which, through a misunderstanding with the king, was prematurely drawn into action and failed hopelessly. In the disastrous days which followed, Moritz was under the cloud of Frederick's displeasure. But the glorious victory of Leuthen (Dec. 5, 1757) put an end to this. At the close of that day, Frederick rode down the lines and called out to General Prince Moritz, "I congratulate you, Herr Feldmarschall!" At Zorndorf he again distinguished himself, but at the surprise of Hochkirch fell wounded into the hands of the Austrians. Two years later, soon after his release, his wound proved mortal.

ANHWEI (Nganhui), a province of China lying astride the Yangtze-kiang in its final S.W.–N.E. course before it enters on its delta. It has an area of 54,826sq.m. and a population of about 20,000,000 (1920). Anhwei falls into two divisions distinct from almost every point of view. Northern Anhwei, beyond the Hwai-yang shan, belongs physically to the North China Plain; its level surface is liable to flooding by the Hwai-ho and it is covered by river detritus and wind-borne loess. It has too the climate and cultivates the crops (wheat, millet and beans) typical of north China. Southern Anhwei, on the other hand, enjoys a more genial climate and is part of the mountain and valley country of south China. Its hillsides are terraced and planted largely with the tea shrub and its river plains constitute rice-growing paddy-fields. Southern Anhwei is itself divided into two: the northern part is the wide valley of the Yangtze between the Hwai-yang shan on the north and Hwang shan on the south; the southern, at a rather higher elevation, lies south of the Hwang shan. The centre of the northern division, the Yangtze valley, is the capital, Anking, and of the southern division Hwei-chow, a great tea centre. The name An-hwei is compounded out of the first syllables of each. It was not constituted a separate province until the 17th century in the early days of the Ch'ing (Manchu) dynasty and during the preceding Ming dynasty (14th–17th centuries) it formed, together with Kiangsu, the greater province of Kiangnan. Anhwei is therefore one of the more modern artificial provinces and is neither a physical unit nor an historical entity.

ANHYDRIDE, an oxide (*q.v.*) which will combine with water to form an acid (*q.v.*).

ANHYDRITE, a mineral, differing chemically from the more commonly occurring gypsum in containing no water of crystallization, being anhydrous calcium sulphate, CaSO₄. It crystallizes

in the orthorhombic system, and has three directions of perfect cleavage parallel to the three planes of symmetry. Distinctly developed crystals are somewhat rare, the mineral usually presenting the form of cuboidal cleavage masses. The hardness is $3\frac{1}{2}$ and the specific gravity 2.9. The colour is white, sometimes greyish, bluish, or reddish. On the best developed of the three cleavages the lustre is pearly, on other surfaces it is of the ordinary vitreous type.

Anhydrite is most frequently found in salt deposits, but it is only met with at some depth; nearer the surface it has been altered to gypsum owing to absorption of water.

A peculiar variety occurring as contorted concretionary masses is known as tripe-stone, and a scaly granular variety, from Vulpino, near Bergamo, in Lombardy, as vulpinite; the latter is cut and polished for ornamental purposes.

ANI, a ruined ancient city in the Armenian S.S.R. (anc. *Abnium*). Altitude 4,390ft. In A.D. 961 it was the capital of the Bagratid kings of Armenia; later it was known as the city of 1,001 churches; frequently besieged by Turks, Georgians and Mongols, it was finally ruined by an earthquake in 1319. The double wall, partly in ruins, remains, and also 11th, 12th and 13th century churches are extant.

See M. F. Brosset, *Les Ruines d'Ani* (St. Petersburg, 1860-61).

ANICETUS, Pope (c. 157-168). It was during his pontificate that St. Polycarp visited the Roman Church to confer with him about the Paschal controversy.

ANICHINI, LUIGI, Italian engraver of seals and medals, a native of Ferrara, lived in Venice about 1550. Michelangelo pronounced his "Interview of Alexander the Great with the high-priest at Jerusalem" "the perfection of the art." His medals of Henry II. of France and Pope Paul III. are highly valued.

ANILINE, PHENYLAMINE or **AMINO BENZENE**, an organic base first obtained from the destructive distillation of indigo in 1826 by O. Unverdorben, who named it Crystallin ($C_6H_5NH_2$). In 1834, F. Runge isolated from coal-tar a substance which produced a beautiful blue colour on treatment with chloride of lime; this he named kyanol or cyanol. In 1841, C. J. Fritzsche showed that by treating indigo with caustic potash it yielded an oil, which he named aniline, from the specific name of one of the indigo-yielding plants, *Indigofera anil*, *anil* being derived from the Sanskrit *nīla*, dark-blue, and *nīlā*, the indigo plant. About the same time N. N. Zinin found that on reducing nitrobenzene a base was formed, which he named benzidam. A. W. von Hofmann investigated these variously prepared substances, and proved them to be identical, and thenceforth they took their place as one body, under the name aniline or phenylamine having the composition $C_6H_5NH_2$. Pure aniline is a basic substance of an oily consistence, colourless, melting at -8° and boiling at 184° C; it dissolves in 31 parts of water. On exposure to air it absorbs oxygen and slowly resinifies, becoming deep brown in colour. It possesses a somewhat pleasant vinous odour and a burning aromatic taste; it is highly poisonous, having a destructive action on the red corpuscles of the blood.

Aniline is a weak base and forms salts with the mineral acids. Aniline hydrochloride forms large colourless tables, which become greenish on exposure; it is the "aniline salt" of commerce. Although aniline is but feebly basic, it precipitates zinc, aluminium and ferric hydroxides from their salts, and expels ammonia from ammonium compounds when warmed with them. When aniline hydrogen sulphate is baked at 200° C sulphanic acid,

is produced. Anilides, compounds in which the amino-group is substituted by an acid radical, are prepared by heating aniline with certain acids; antifebrin or acetanilide (*q.v.*) is thus obtained from acetic acid and aniline. When aniline vapour and hydrogen are passed over finely divided nickel heated at 190° C., the reduction products, *cyclohexylamine*, *dicyclohexylamine*, and *cyclohexylaniline* are produced. The oxidation of aniline has been carefully investigated. In alkaline solution azobenzene results, while arsenic acid produces the violet colouring matter, violaniline. Chromic acid converts it into quinone, while chlorates, in the presence of certain metallic salts (especially of vanadium), give

aniline black. Hydrochloric acid and potassium chlorate give chloranil. Potassium permanganate oxidizes it, in alkaline solution to azobenzene; Caro's acid, H_2SO_5 , converts it into nitrosobenzene. Hypochlorous acid gives para-amino-phenol and para-amino-diphenylamine (E. Bamberger). Bleaching powder gives a purple coloration.

The great commercial value of aniline is due to the readiness with which it yields, directly or indirectly, valuable dyestuffs. The discovery of mauve in 1858 by Sir W. H. Perkin was the first of a series of dyestuffs which are now to be numbered by hundreds. Reference should be made to the articles DYES, SYNTHETIC; FUCHSINE; SAFRONINE; INDULINES, for more details on this subject. It is a starting-product for the manufacture not only of dyestuffs but of many drugs.

Aniline is manufactured by reducing nitrobenzene with iron borings and water slightly acidified with hydrochloric acid, the product being purified by steam distillation followed by distillation under reduced pressure. Monomethyl- and dimethyl-aniline are colourless liquids prepared by heating in an autoclave at 220° aniline, aniline hydrochloride and methyl alcohol, or aniline, methyl alcohol and about 0.5% of iodine. They are of great importance in the colour industry. Monomethylaniline boils at $193-195^\circ$; dimethylaniline at 192° . (See also AMINES.)

ANIMAL, a term first used to denote a living thing, but now used to designate one branch of living things as opposed to the other branch known as plants. Until the discovery of protoplasm, and the series of investigations by which it was established that the cell was a fundamental structure essentially alike in both animals and plants (*see* CYTOLOGY), there was a vague belief that plants, if they could really be regarded as animated creatures, exhibited at the most a lower grade of life. We know now that in so far as life and living matter can be investigated by science, animals and plants cannot be described as being alive in different degrees. Animals and plants are extremely closely related, alike in their fundamental characters, and each grading into organisms which possess some of the characters of both classes or kingdoms (*see* PROTISTA). The actual boundaries between animals and plants are artificial; and are solely due to the ingenious analysis of the systematist. The most obvious distinction is that the animal cell-wall is either absent or composed of a nitrogenous material, whereas the plant cell-wall is composed of a carbohydrate material—cellulose. The animal and the plant alike require food to repair waste, to build up new tissue and to provide material which, by chemical change, may liberate the energy which appears in the processes of life. The food is alike in both cases; it consists of water, certain inorganic salts, carbohydrate material and proteid material. Both animals and plants take their water and inorganic salts directly as such. The animal cell can absorb its carbohydrate and proteid food only in the form of carbohydrate and proteid; it is dependent, in fact, on the pre-existence of these organic substances, themselves the products of living matter, and in this respect the animal is essentially a parasite on existing animal and plant life. The plant, on the other hand, if it be green, containing chlorophyll, is capable, in the presence of light, of building up both carbohydrate material and proteid material from inorganic salts; if it be a fungus, devoid of chlorophyll, whilst it is dependent on pre-existing carbohydrate material and is capable of absorbing, like an animal, proteid material as such, it is able to build up its proteid food from material chemically simpler than proteid. On these basal differences are founded most of the characters which make the higher forms of animal and plant life so different. The animal body, if composed of many cells, follows a different architectural plan; the compact nature of its food, and the yielding nature of its cell-walls, result in a form of structure consisting essentially of tubular or spherical masses of cells arranged concentrically round the food-cavity. The relatively rigid nature of the plant cell-wall, and the attenuated inorganic food-supply of plants, make possible and necessary a form of growth in which the greatest surface is exposed to the exterior, and thus the plant body is composed of flattened laminae and elongated branching growths. The distinctions between animals and plants are in fact obviously secondary

and adaptive, and point clearly towards the conception of a common origin for the two forms of life, a conception which is made still more probable by the existence of many low forms in which the primary differences between animals and plants fade out.

An animal may be defined as a living organism, the protoplasm of which does not secrete a cellulose cell-wall, and which requires for its existence proteid material obtained from the living or dead bodies of existing plants or animals. The common use of the word animal as the equivalent of mammal, as opposed to bird or reptile or fish, is erroneous.

For the classification of the animal kingdom, see ZOOLOGY.

ANIMAL BEHAVIOUR. To give a plain tale of this or that instance of animal behaviour is not easy. The language in which it is described nearly always introduces words which imply more than can be seen. And what most people want is not only a plain tale of that which one can see, but an interpretation in terms of which one may, in some wise, account for the observable behaviour.

Three Instances of Behaviour.—Let us keep as near as we can to simple description of three selected episodes in the life-history of three widely different animals.

(1) Carmine particles are suspended in the water in which the unicellular organism, *stentor*, is under observation. At first the behaviour is not visibly affected. After a while the animalcule turns this way and that. Then there is reversal of the ciliary action in the wreath that surrounds the mouth. Later on, the *stentor* withdraws into its sheath. Then it breaks away and swims off. Such is a plain tale of facts which Professor Jennings has placed on record.

(2) Under experimental conditions some chicks, a few days old, are quietly feeding. Maggots seem specially attractive. Each time a selected chick is about to seize a maggot a toy pistol is fired at some little distance, out of sight. Each time the chick starts and turns aside. After about a dozen repetitions of this procedure the pistol is no longer fired. None the less there is aversive behaviour at sight of a maggot. During the next day no maggots are eaten by this chick.

(3) Suitably placed before an orang-utan, Julius, are nine compartments. Food can be obtained by passing through one of them. The entrance doors are visibly open or shut. Matters are so arranged that, on different occasions, or "settings," three consecutive doors are open—2, 3, 4; 7, 8, 9; and so on. But only by entering the left-hand door of the three, and passing through this compartment, can food be obtained. In some ten observations on each of 24 days there is no difference of behaviour in relation to "this" rather than "that" of the three open doors. On the 25th day the left-hand door is entered on each of the ten settings. On the following day a series of ten settings, different from those of the preceding days, is responded to promptly, readily, and without a mistake. Further details are given by Prof. Yerkes.

Scientific Interpretation.—If one start with the behaviour of *stentor*, one has, under interpretation, to take account of (1) the external conditions of stimulation, and (2) the internal state of the organism. The external conditions are pretty constant. The internal state appears to pass through several step-like changes; and at each change of state the observed behaviour is different (Jennings). It seems, then, that under the continuous influence of similar external conditions there is an order in which the internal changes of state occur. But what is seen is a routine in modes of behaviour, from which the changes of state may be inferred. Assuming that this inference is valid we may say: given the continuance of these external conditions; and given this or that internal state of the organism then such and such is the behaviour. When we can say this we have so far a scientific interpretation of what happens.

There are many who urge that, so long as we keep within the domain of inductive science as they define it, this is all that we are justified in saying. But there are others who urge that in saying this and no more one does not really "account for" what happens in this or any other instance of animal behaviour. To account for what happens, it is said to be imperative that an answer be given to the question: through the operation of what

agency, as efficient cause, is this or that manner of behaving to be explained?

When this question is raised one enters a region of acute controversy. But need we enter this region? May it not be better to shun controversy by discussing animal behaviour in a delimited domain of inquiry—a domain which is common to disputants on this side and on that? If so we should formulate concisely what lies within this delimited domain. It is for us that domain in which the canon of interpretation runs: given such and such relations of the animal to surrounding events, and given such and such relations of events within the organism, then such and such is the observable behaviour.

In what was said above with regard to an interpretation of the behaviour of *stentor* we kept within this domain. It may, however, be objected that such an interpretation is wholly in terms of physical conditions external to the organism, and of physiological states within it. Is that so? Does our statement imply that physical and physiological relations only are present, and that mental relations, in some comprehensive sense of the word "mental," are absent? It does not. That would imply that we are quite arbitrarily to exclude from our survey of animal behaviour a kind of relatedness that is assuredly inferable from much of the behaviour of more highly developed organisms.

It is here that difficulty attends our starting with the behaviour of *stentor* rather than with that of the orang-utan. There are few who deny that mental relations have being and play some part in the behaviour of the anthropoid apes. There are some who say that there is no evidence of any relations of the mental kind in the unicellular organisms. We must, however, accept some hypothesis on which to conduct our enquiry. As an hypothesis, frankly entertained as such, let us proceed on the supposal that relations of the mental kind are present in all instances of animal behaviour. For lack of better words, let us say that in *stentor* there is some "percipience" having reference to external events, and some "sentience" concomitant with the internal changes of state. Let us assume that in any living animal there are not only relations of the physical and physiological kind, but also relations of the mental kind. Nay more, let us chiefly consider the part that mental relations play in animal behaviour. The emphasis here is on relations. Efficient causality is not within our province. Let us keep to our canon of interpretation, and say: Given such and such relations, physical and mental (a) of the organism to its surroundings, and (b) within the organism, such and such is the observable behaviour. On this hypothesis, since relations of both kinds are always present, the question does not arise: Would the behaviour be just the same were either kind of relatedness absent? *Ex hypothesi* neither kind is absent in any instance of animal behaviour.

It may, however, be said: Even if it be granted that in all instances of animal behaviour both kinds are in being, it does not follow that the presence of mental relations makes any difference in the course of events. The implication here is that the presence of physical relations does make a difference. But what is meant by the ambiguous expression "make a difference"? In one sense whether they do or do not make a difference, in the case of *stentor*, or the chick, or Julius the orang, is a question of evidence—or more strictly the question how best to interpret the available evidence. But in another sense it is the operation of some Force that is invoked to explain what makes the difference. Such explanation lies beyond our purview, since the concept of Force in this sense—any Force, whether mechanical or vital or other—is borrowed from the vocabulary of a philosophy which deals with efficient causality. One may hazard the assertion that this concept has no place in modern physics as a branch of science. In any case it has no place in our canon of interpretation. In formulating such a canon one's aim is (1) to include all kinds of relations which may be inferred from what we observe in the whole range of animal behaviour; and (2) to exclude from our inquiry an issue that is the storm-centre of much philosophical controversy.

Primary and Secondary Behaviour.—Proceeding on the method thus indicated, we accept the hypothesis that relations

of the mental kind are in being in every instance of animal behaviour. We accept also the hypothesis that in what we may speak of as "primary behaviour," that of *stentor* for example, percipience has reference at some given "now" to that from which physical influence is then and there received. Thus far, therefore, we entertain two supposals: (1) that even in one of the unicellular organisms there is percipience, as a primitive form of reference to the external world, and sentience, as a primitive mode of that which Professor Alexander speaks of as enjoyment; (2) that, at the level of primary behaviour, percipience is in being only at the moment of receipt of physical influence from surrounding events.

We now pass to the behaviour of the chick as an instance of what may be called "secondary behaviour." We have here a much more highly developed animal in which there is a "synaptic" nervous system. When we try to get down to essentials we must ask: What is the salient difference which distinguishes secondary from primary behaviour? So far as mental relations are concerned, may we not find a clue in the further supposal that secondary behaviour implies reference that is no longer confined to the moment of receipt of physical influence? The hypothesis then is that there is not only percipient reference on receipt of influence now, on this occasion, but also what we may call "supplementary reference" to the like of that which was the source of such influence on some previous occasion or occasions. To percipience is added that "meaning"—in some sense of this word—which raises bare percipience to the level of naïve perception. Then we may say: Given this mode of mental relatedness, such and such modification of the course of behaviour is observed.

Apply this to the selected instance of secondary behaviour. On the first occasion, when the pistol was fired, there was, we assume, percipience and sentience with which a specific mode of primary behaviour was linked up in accordance with the hereditary nature of the bird and the build of its nervous system. On this first occasion, however, there is no call to go beyond percipience and sentience as relations of the mental kind. The behaviour described as "starting and turning aside" is, on the first occasion, primary. And in so far as on subsequent occasions like behaviour is repeated *da capo*, it is still of the primary order.

But on some subsequent occasion the maggot is avoided at sight. The aversive behaviour—an observable change of attitude—is in evidence in the absence of the external conditions which on the first occasion elicited this specific response. Furthermore, the behaviour we describe as "seizing and swallowing," primary in origin, which on previous occasions was elicited at sight of the maggot, is no longer elicited. There is thus an observable difference of behaviour on earlier and on later occasions. On earlier occasions under receipt of physical influence we have *this* mode of stimulation and percipience, linked with *this* mode of behaviour and concomitant "enjoyment" in thus behaving. But on later occasions we have *this* mode of stimulation (visual) linked with *that* mode of behaviour (aversive).

What here calls for interpretation is the switching off of responsive action in such wise as to give this observable outcome. It is clear that the interpretation should be sought in some *internal* conditions within the organism that is in receipt of stimulation. For under closely similar external conditions the behaviour is different on the first and on some later critical occasion. This sets a problem for physiology. The switching off seems in large measure to be interpretable in terms of the opening up of functionally new routes—secondary connecting-routes—in the central nervous system. This is discussed under the heading of the "conditioned reflex." One cannot enlarge upon it here. Two things may be noted: (1) that the connection is such as to link the afferent or receptor limb of "this" primary route with the efferent or effector limb of "that" primary route; (2) that the reorganisation effected in this way is acquired in the course of individual life.

However it be interpreted physiologically there is some specific change within the organism—almost certainly within the synaptic nervous system, probably only when there is a nervous system of this type—such as to provide for a new distribution of behaviour-output on receipt of physical influence on the sensory

receptors. And this redistribution of output, distinctive of the wide range of secondary behaviour, is relatively abiding. But the more primitive distribution, initially inherited, may at times be reinstated. The old primary "this-to-this" routes seem to be re-opened in certain states of the organism.

To the internal states and the part they play in animal behaviour we shall have presently to direct consideration. Here it is in place to emphasize two things: (1) that the redistribution of behaviour-output entails a redistribution of naïve perceptual reference; (2) that the latter redistribution is of the cognitive type, with supplementary reference and the acquisition of fuller "meaning."

In the naïve perception of animals this "meaning" is probably referred to the external situation as a whole. The analysis of this whole into "objects" in relation to each other and to the percipient, and its resynthesis "as a whole," comes only with reflective thought. None the less behaviour is commonly centred on something salient in the external situation which *we* reflectively recognize as an object in relation to its surroundings and to us. In the genesis of objective reference in the animal, as in the human infant, primary behaviour thereto leads and carries with it such "meaning" for further behaviour as the secondary step in advance entails.

In the selected instance of secondary behaviour, we have, in effect, distinguished (a) the external situation to which there is perceptual reference on receipt of physical influence therefrom, and (b) the internal situation—the existing condition and state of the organism. What seems to be essential is that the chick behaves as if a sound-shock formed part of the external situation, although there is no receipt of any such physical influence. We resort, therefore, in accordance with the method of science, to hypothesis. We ask: Is there not in the internal situation supplementary reference to something more than is physically present in the existing external situation? If so that "something more" is what we speak of as "meaning"—practical meaning for the guidance of behaviour.

Of course it may be said that on later critical occasions the chick "remembers" the sound-shock received on prior occasions; or that a sound-shock is present in "expectation." Under suitable definitions such language is permissible. In us, however, memory implies reflective reference to incidents dated in the conceptualised past; and expectation implies reference to incidents in the future as we conceive that it will be. Hence it is better in discussing animal behaviour to use words of less reflective import. It is well to avoid the word "purpose," since this word is specially earmarked by some controversialists to emphasize the concept of mental *agency*. Even the word "meaning" is likely to suggest some tinge of that reflective *significance* which it commonly carries in current speech. Since, however, the animal lives forward, what has been spoken of as supplementary reference (to avoid reflective implications) has presumably "prospective meaning" in the sense that, to be of practical avail the reference is to that which, through behaving forward, will be secured or avoided.

But the question still remains: How is it that certain events which form part of the *internal* situation, and are interpretable as due to excitation from within *via* connecting neurone-routes—how is it that these events, in their mental relations, carry supplementary reference to the *external* situation? All that one can say is that there seems call for the supposal that they do so in animals as in us. If these events, whatever they may be, carry percipient reference when they are initially instated from without, it is not unreasonable to suppose that they retain like reference when their likes are subsequently reinstated through excitation from within.

The Behaviour of the Orang. Foreplans of Action.—In the earlier days of the life of any animal in which a synaptic nervous system has been evolved, there accompanies progressive "conditioning," progressive expansion of "prospective meaning." In later days this reaches such level of attainment as the status of organism permits. The chief turning-point in the evolution of animal behaviour is the critical passage in mental reference from primary to secondary. But when the secondary comes, the primary does not go. In all perception there is a central core of percipience.

In some animals, however, behaviour is raised to a higher level. This is illustrated by the procedure of Julius the orang. Here the presumptive evidence suggests that on some critical occasion there is what one may speak of as a "mental foreplan of action." It arises in the internal situation. But it has *reference* to the external situation as objectively "in mind" at the time-being.

The physiological counterpart of this higher form of reference seems, from the work of Professor Bianchi and others, to be, in mammals, a "conditioned" nexus of interconnecting neurone-routes in the frontal region of the cerebral cortex. This statement is necessarily somewhat technical. The point for emphasis is that we may infer a gradually acquired structural plan in a specialized part of the brain, which takes referential form pretty suddenly, as a foreplan of the objective situation; and that this mental foreplan thereafter serves to guide behaviour in like situations.

There is little question that a cognitive attitude of this sort reaches a higher level in such apes as the orang and the chimpanzee than it does in the monkeys. But whether this step in advance involves something new in principle or only added complexity is open to question. A good deal lower in the mammalian scale, it is difficult to interpret such behaviour of the rat, as has recently been described with admirable care by Professor McDougall, save on the hypothesis of foreplans of action. More questionable is the presumptive evidence of such mental plans of action in birds—partly because in their later life the major episodes seem so largely to be modes of behaviour in which hereditary rather than acquired factors are dominant.

It should be remembered that all behaviour, in detail if not in its secondary integration, is so to speak built to the plan of the organism that behaves. This is so even in *stentor*. It is so in all primary behaviour. But when the rubicon of the secondary is overpassed there seem to be two—no doubt quite probably more than two—critical "moments" of mental advance correlated with physiological advance; first, that at which reference becomes supplementary and prospective, and thereafter the "crystallizing out" of such reference in a mental foreplan of action. It is the task of comparative neurology and of comparative psychology (*q.v.*) to work out the details. The careful observations of Professor Yerkes, Dr. Köhler, and others, have shown how highly developed in the anthropoid apes is supplementary reference to a complex external situation in presence of which they behave, as we infer, with a foreplan in mind; and how nicely adapted to special circumstances are many of their feats of skill. It may be that some apes have overpassed the next critical stage in onward advance—that in which action is not only *carried out* to a successful outcome, but is *interpreted* in a reflective "framework of reference" under conceptual thought. This must be kept in view as an open possibility. But, as at present advised, the writer is of opinion that, on the available evidence, in man only is reflective thought developed. If so its interpretation does not fall within the scope of a discussion of animal behaviour.

The Part Played by Internal States.—The emphasis thus far falls on those mental relations which are, broadly speaking, of the cognitive order. It is noteworthy that, no matter how highly elaborate in effective detail may be the primary response to adequate stimulation on some first occasion or on subsequent *da capo* occasions—and it is often highly elaborate—still, as primary, it lacks that supplementary reference which is distinctive of the secondary step in advance.

On the physiological side we have seen that interpretation of the internal situation lays stress on the provision in a synaptic nervous system for conditioned response to stimulation. So too in the frontal lobes of the mammalian brain there is provision for an acquired nexus of neurone-routes. From such more or less abiding "conditioning" of the central nervous system let us distinguish the more labile internal state of the animal. The internal state then denotes the changing physiological poise of the organism as a whole at some given time. This is not only in a general way dependent on the reciprocal interaction (however brought about) of all the organs and tissues on each other; it is dependent in a special way on the influence of the internal secretions of certain endocrine glands transmitted by the blood stream to the fluid in

which the tissues are bathed. Their influence on all that intervenes, including the passage of nerve impulses along neurone-routes, between receipt of stimulation and overt behaviour consequent thereon, is subtle and penetrating. It is not improbable that changes of state or physiological poise are subject to hereditary transmission and thus modify the number of occasions requisite for the acquisition of a conditioned response.

One cannot follow up these intricate clues to physiological interpretation. The mental concomitant of the internal state of the body is sentience and the affective enjoyment founded thereon. It becomes integrated as that which may be spoken of as the "self of enjoyment." We must take for granted that in animals, as in us, it is pleasurable toned or the reverse. We want to get at that which is essential in principle with respect to the rôle that is played by internal states. Here and now, while they are in being, they raise or depress the vigour of animal behaviour, and, by differentially raising or depressing, they modify the course of that behaviour. The stress is on *here and now*. It matters not whether cognitive reference be prospective, or whether a foreplan of future action be, or be not, in being. What matters is the state of the organism; and that state is here and now. Here and now is the behaviour the current course of which is felt as enjoyment in behaving. Here and now, too, is enjoyment in perceiving. It is only that *to which perceiving has reference* that is other than here and now. The affective state, in animals as in us, is always that of the current time-being.

We have sought to distinguish (1) the plain tale of the behaviour we observe; (2) the cognitive reference with which we credit the animal; (3) the affective state which may be inferred. But we often use one word to do duty for all three. One says, for example, that some male bird shows "hostility" when another male crosses the bounds of his territory. Under this one word is comprised (1) how he behaves; (2) his cognitive attitude, probably on later occasions with prospective reference to the further behaviour of the "intruder"; (3) what he "feels like" then and there. This last is the affective state as such. The point for emphasis is that this affective state—which we can only describe in terms of what *we* "feel like" on what we deem to be analogous occasions—is here and now, and if not here and now leaves behaviour "unaffected."

Instinct and Intelligence in Animals.—For popular thought the leading question with respect to any instance of animal behaviour takes the form: Is it instinctive or intelligent? The word "instinctive" is here commonly applied to an approximately invariable manner of behaving that is not "learnt" in the course of individual life, as contrasted with the more variable manner of behaving which is so learnt and which therefore betokens intelligence on the part of the animal.

To account for intelligent behaviour it used to be deemed sufficient to say that what is learnt by the animal is the outcome of that profiting by experience with which we are familiar in our own life. To account for instinctive behaviour there was recourse either to inherited experience or to inherited structural organization of the nervous system. Some said: Just as intelligent habits are acquired and become automatic in the course of individual life, so have the more typical instincts been similarly acquired and have become automatic in the course of racial life. Others said: Just as the hereditary mode of development of the plumage of a bird is interpretable biologically, so is the hereditary manner in which that plumage is displayed on some first occasion of courtship biologically interpretable.

Discussion on lines such as these is now somewhat out of date. More up to date, as things are, is the discussion of instinct and intelligence in terms of diverse expressions of that *élan vital* which—as some assert, and others roundly deny—must be invoked to explain all that happens in any living creature. Thus is raised the controversial issue which it has been our aim to avoid by delimiting the domain of our inquiry.

Apart, however, from this further issue, the words "instinctive" and "intelligent" will for long continue in popular use with signification best inferred from the context. The context for most people is seldom that of *stentor*, or even that of the sea-anemone

or starfish. It is generally that of behaviour of animals in which both sensory and motor organs are well developed, and in which there is a highly organized (technically "synaptic") nervous system. It is generally also a context in which arises the question: Is the behaviour in evidence instinctive or intelligent? This implies some doubt as to which it is. If certain salient features of the behaviour are clearly the outcome of prior experience acquired in the course of individual life, the procedure is spoken of as that of an intelligent animal—and the more nicely adaptive it is in this way, the more intelligence is attributed to the animal. If, on the other hand, the predominant feature is *not* the outcome of prior experience, it is called instinctive—and the more adaptive it is in an inherited and unlearned way, the more typically instinctive, rather than merely reflex, is such behaviour.

If this gives adequate expression to the popular attitude, how does it stand in relation to the foregoing treatment? The behaviour commonly called instinctive, in so far as it is unconditioned and carries no supplementary reference, is that which has been spoken of as "primary" in the context of such animals as birds for example. The behaviour commonly regarded as betokening intelligence is at a fairly high level of that which has been spoken of as "secondary," and more especially that which seems to imply a foreplan of action.

ANIMAL BREEDING. The aim of the breeder is to obtain and maintain generation by generation improvement in the sum of the desirable qualities exhibited by his stock and to eliminate qualities regarded as undesirable. His task is that of producing true-breeding types which, under the circumstances in which they are to be maintained, shall flourish and fulfil the purposes for which they were bred. Before there can be improvement there must be a standard of the ideal. Often it is a simple matter to assess the value of an individual or type in relation to the purposes for which it has been bred: in the case of dairy cattle and sheep, for example, it is possible to determine the quantity and quality of milk and wool and to use such determinations as guides in breeding practices. In the case of meat-producing animals the value of the individual cannot be assessed at all accurately until after slaughter, and breeders have been obliged to rely largely on outward signs that are not always trustworthy indications of quality. In the case of work-animals it is exceedingly difficult to assess potential usefulness, since no final test can be reached until the end of the working life, and here too breeders have been forced to adopt somewhat unsatisfactory empirical standards. It is a general rule that the simpler and more direct the test of utility is, the easier and the more rapid will improvement be.

In the task of securing breed improvement the breeder seeks to control (1) the environment of his stock, and (2) the forces of heredity and reproduction. With regard to the first, conspicuous improvement has followed directly upon advances in knowledge of animal nutrition and disease and of the general biology of the animals concerned. Such improvement is but temporary, however, and can only be maintained by ceaseless care. There is too a limit to such advance, and when this is reached further progress can only be made by deliberate control of the inborn qualities of the stock.

When the great pioneers first undertook the improvement of British livestock about the middle of the 18th century (see AGRICULTURE), the farm animals were of very mixed type and generally of poor quality. Certain local types were distinguished by peculiarities of size, prevailing colour and productiveness, but there were no breeds in the modern sense, and in all these local types there was great variability in respect of all characters. The modern breeds had thus their beginnings in the picture of an ideal type at which the breeder aimed, and in the fortunate and fortuitous appearance of one or more superior individual animals. Having this ideal in mind, the breeder chose from among the local stock individuals which exhibited one or more of the components

of his ideal. The initial stages in the improvement of each breed was the collection, in as small a group of the local type as possible, of as many of the characters of the ideal as possible. The breeder has not the power of producing hereditary characters, desirable or undesirable, but only of creating any combination of such heritable characters as already exist separately, and of manipulating the environment so that these become more fully expressed.

Having started on a basis sufficiently wide to ensure the inclusion of all the characters that were esteemed, the second stage in improvement has been the fixing of the desired characterization of the stock and the elimination of undesirable qualities. By the selection of individuals in each generation as parents of the next, the breeder has sought to weed out the undesirable characters and to combine the desirable, first in one or two individuals, and finally throughout a true-breeding strain. He has selected the animals for breeding and controlled their matings. Though this process of selection has never yet been carried to the point of complete and final success, it has played an all important rôle in all instances of breed improvement.

Selection.—The simplest form of selection for breeding purposes is that which is termed "mass" selection, the choice of individuals on the simple basis of individual merit as judged by appearance or performance without reference to ancestry, progeny, or to the degree of the relationship of the individuals concerned. The application of this kind of selection has given widely different results according to the kind of characters in relation to which it has been employed. For the purpose of changing the average characterization of a stock, mass selection has usually been applied to such characters as show a quantitative variation. The breeder has selected continuously, generation after generation, such individuals as showed a slight variation in the desired direction, as increased size, improved shape or pattern. The breeder quickly found that certain characters yielded very rapidly to such selection up to a given point, after which the method proved ineffectual. In other instances such selection yielded no advance, and so it is that till quite recently there has been no general explanation of the manner in which mass selection sometimes accomplishes its aims and in certain instances fails to do so. An entirely satisfactory explanation has been disclosed within the last 20 years. It has been shown that mass selection is only followed by a movement in the desired direction when applied to a population or stock that is heterozygous for many of its characters, and when the characters for which selection is being practised are inherited in a straightforward fashion, not being conditioned in their expression to any marked extent by the conditions of nurture (see MENDELISM and HEREDITY). In the dairy cow, for example, the characters of the milk yield and composition are conditioned in their expression not only by the effects of age, time of calving, and feeding, but also by a multitude of environmental agencies, the total influence of which cannot yet be assessed. Selection will not lead to so great advance in a case such as this as it will when applied to the case of a simple recessive character the expression of which is in no way influenced by environmental agencies. It is a simple and rapid matter to establish a true-breeding strain of red cattle by selecting for breeding the occasional red that crops up in black breeds, but the same methods will not yield a true-breeding roan or blue if, as seems the case, these coat colours are peculiar to unfixable heterozygotes.

The result of such selection, when effectual, is the isolation of individuals homozygous and therefore true-breeding for the characters for which selection is being practised, and so it is that when complete homozygosity has been attained, further selection is unavailing. It is for this reason that mass selection is relatively ineffectual in changing the characters of well established breeds. That this method has been and still is so successful is explained by the fact that most domesticated animals are so heterozygous that selection practised on ordinary stock is bound to be followed by some advance in quality.

Selection can create nothing; it merely sorts out individuals and types homozygous for the characters for which the breeder is aiming, and alters the average characterization of the stock by altering the proportions of the different hereditary constitutions

within it. Commonly it is impossible to disentangle the effects of selection in the production of improved types from those consequent upon advances in husbandry inevitably developed in the case of a stock which is becoming more and more valuable to its owner.

Pedigree and Progeny Test.—Appearance alone is not a reliable guide to breeding ability. This was a lesson quickly learned. The acid test of the worth of the sire and dam is that it shall beget offspring certainly not less valuable and preferably more valuable than itself. Selection on an estimate of the hereditary constitution of the individual is revealed in its pedigree and in its progeny. Pedigree, when rationally used, forms a valuable aid to the breeder in his work of selection, but its importance can be, and commonly is, over-emphasized. Individual merit is a safer guide than pedigree, but the two in conjunction are better than either alone. From the pedigree the breeder seeks information concerning the average merit of the immediate ancestors, not merely of sire and dam, grandsire and granddam, but also of their brothers and sisters, and also indications of the orderliness and mode of inheritance of these good qualities from generation to generation. Commonly too much importance is paid to more remote ancestors and to descent in the direct female line from some particular "foundation female." There is no biological justification for this.

Though it is sound policy to use for breeding only those individuals of manifest merit out of admirable and true-breeding parents, the real test of breeding worth is the progeny test. The breeding value of an individual is estimated by examination of a sample of its early progeny. The progeny test is applied most readily to males because of the greater number of offspring which may be obtained from a single individual and because the flock or herd can be improved more rapidly in this way than through the selection of superior females, in the case of which half the breeding life must be over before a sufficient number of offspring has been secured. Those males which beget the best progeny are retained, the others, even though in general appearance better specimens, are discarded. The test of a dairy bull, for example, is the average milk-production of a number of his daughters compared with that of their dams, assuming, of course, that the conditions of husbandry are similar in the two cases. To compare the merits of different sires in the bacon pig, it is necessary to rear, under carefully controlled conditions, groups of at least four offspring of each sire and finally to convert them into bacon.

Systems of Mating.—Having secured individuals of merit for breeding, the next step is to mate them. The object in mating is to produce another generation, of equal or finer merit, to multiply the number of individuals exhibiting the desired qualities and to eliminate inborn variability.

In the early days of breed improvement, the problem of deciding which individuals should be mated did not exist. The improver found it increasingly difficult to find in other stocks animals which approached his ideal as nearly as did animals in his own, and so he was forced by circumstances to inbreed. So it was that Robert Bakewell (*q.v.*), when he found that he could mate closely related animals without disadvantageous results, resorted, as his blood lines became more and more intermingled, to more and more intensive inbreeding. Since his time all efforts towards the production of uniform and valuable breeds, have involved, sooner or later, the deliberate mating of closely related individuals.

Inbreeding.—Inbreeding (*q.v.*), in practice, is the term restricted to describe the matings of close relatives, *e.g.*, brother and sister, parent and offspring, and matings between comparatively unrelated or only distantly related individuals are described as outbreeding. Matings involving individuals of different breeds or varieties are examples of crossbreeding. Line-breeding involves matings between relatives in an attempt to increase or concentrate in one line of descent the hereditary constitution of one or a few individuals. All these systems can be grouped under the two headings of inbreeding and outbreeding, these differing one from the other only in the degree of relationship of the individuals concerned. Inbreeding is not necessarily harmful but can be definitely advantageous, leading to the development of a uniform and true-breeding stock. It is equally true, however, that benefit

does not always follow this practice, for in certain cases there has been, and under experimental conditions still is, disappointing regression, diminution of vigour, lowered powers of resistance, decreased fertility, even reduction in size. In human societies this disagreement has resulted in laws and customs as diverse as those which forbid marriages outside a restricted group of relatives and those which forbid matings between relatives altogether. Though the facts vary, however, there has grown up amongst students of heredity a considerable degree of unanimity concerning the principles involved and a general interpretation has been promulgated which explains the conflicting results scientifically. The effects of inbreeding depend, not on any pernicious attribute of this system of mating, but upon the hereditary constitutions of the individuals involved. Inbreeding has but one demonstrable effect upon the stock subjected to its action—the isolation of homozygous types. It can be stated confidently that no individual is homozygous for all the characters which it exhibits (*see MENDELISM*).

In the case of an undesirable character that is dominant, it will be eliminated either by its effects upon the individual or by artificial selection as practised by the breeder. If the undesirable character is a recessive, however, it will remain hidden in the stock until two individuals, each heterozygous in respect of it, are mated. If only one animal in ten carries the factor for such a recessive character and mating is at random, one individual in every four hundred of the next generation may be expected to exhibit this undesirable character, and even though there are 20 factors for different undesirable recessive characters among the stock and these are distributed in the same proportion, still 95% of the progeny will not exhibit these characters. But when mating ceases to be at random and related individuals are used, the probability that the two parents each carry the factor for some undesirable character is greatly increased and the proportion of the progeny exhibiting the undesirable character is also raised.

Inbreeding leads to a rapid increase in homozygosity, and when this state has been achieved, stability and uniformity will be reached. But as this process proceeds, there is an inevitable reshuffling of all factors, and so it is that individuals will appear which are homozygous for recessive characters which are definitely deleterious to their possessor. The weak, sterile, and abnormal individuals which appear amongst the offspring of an inbred line are such as have received during this process of the reshuffling of the hereditary factors those which correspond to undesirable recessive characters, these factors ultimately coming to be present in the duplex state. Such individuals will be eliminated, whilst, on the other hand, others which, thanks to this same process, have come to possess the factors for desirable factors in the duplex state, will show improvement over their ancestors. Rigorous selection from amongst these improved types will isolate strains that will compare very favourably with the original stock.

If inbreeding results in disappointment, all that has happened is that disadvantageous characters, the ingredients of which were previously hidden and unexpressed, have been brought to light. Inbreeding thus purifies a stock. This system of mating may be disastrously expensive if the ingredients of hereditary combinations which result in undesirable or non-viable types pre-exist. But, on the other hand, such individuals as have been made homozygous for the desirable characters will be far more valuable material in the hands of the breeder than the stock with which he started, for in virtue of their hereditary constitution they must now breed true. The principal effects of inbreeding are (1) a reduction of variability in the expression of inherited characters within inbred lines or families, and (2) a usual, but not inevitable, decline in general vigour. Line-breeding and family-breeding are merely inbreeding in a less intensive form and may therefore be expected to yield the same results in a longer period of time.

Outcrossing.—Having secured, through inbreeding, strains fairly homozygous for the characters they display, the breeder is then in a position to use these for the production of types destined for special purposes other than breeding. The highly improved breeds of cattle do not thrive in certain regions, being subject to the attacks of insect pests or unable to withstand the rigours of the climate. Successful efforts to populate such regions with

economically valuable animals have been made. The disease-resistant but economically inferior zebu (*Bos indicus*) has been crossed with cattle (*Bos domesticus*). The crossbred is economically less valuable than the purebred cattle but is superior to the zebu and inherits the latter's powers of disease-resistance. To provide an economically valuable animal that can thrive farther north than purebred cattle, the cross of bison with cattle has been made. The crossbred is inferior to purebred cattle as meat, but is superior to the bison and possesses the latter's powers of withstanding climatic severity.

Since the earliest times, animal husbandmen have been familiar with the observed fact that the first crosses of different breeds or races of the same kind of farm animals commonly exhibit a remarkable sturdiness. This "hybrid vigour" is manifested in different ways. Frequently the crossbred offspring are stronger, attain a larger size, mature in a shorter time than either parental stock, and not uncommonly possess notable powers of resistance to unfavourable conditions. Livestock breeders are well acquainted with this superiority of the first cross for many commercial purposes. As an example, the breeder of cattle will doubtless quote the case of the blue-grey, frosty-coated cattle of Scotland, a combination of Black Galloway or Aberdeen-Angus with white Shorthorn, which have long been deservedly esteemed for their large size, goodly proportions and early marketability. The shepherd will extol the qualities of the Blackface with Border Leicester crosses so popular on account of their quick growth and general usefulness. As an example of a wide outcross deliberately made, the case of the mule may be cited. It is better fitted for certain purposes, in virtue of the hybrid vigour that it exhibits, than either parent.

From critical experimental work undertaken to examine the conclusions of practical men, the following facts have emerged:

(1) Crossbreds do not invariably exhibit this hybrid vigour. Any and all crosses will not produce offspring of greater excellence than their parental stocks.

(2) In those cases in which hybrid vigour is exhibited by the first cross, further crossing of the hybrids results in a manifest decrease of this vigour in subsequent generations. Hybrid vigour is the peculiar possession of the first cross.

(3) In order to obtain hybrid vigour in any degree, it is essential that the two parental stocks shall be unrelated, purebred, and that each shall itself be possessed of qualities that, in relation to the object of the crossing, are excellent.

The explanation of these demonstrable facts concerning hybrid vigour is simple. It will be agreed that in general there is a tendency for the qualities of the parents to be expressed in the offspring. This is the basis for an understanding of the vigour derived from crossing. Every individual is a mixture of desirable and undesirable qualities. In crossing, the qualities of the two parents are pooled; the deficiencies of one parent can be made good by the excellencies of the other, the good of one can be reinforced by the good of the other. If an individual is deficient in any way in its hereditary constitution, there is a good chance that its needs may be supplied when it is crossed with other individuals, since it may well be that their deficiencies are not of the same kind: a pooling of the hereditary resources may easily yield a combination that is better than either of the ingredients alone. Hybrid vigour is based on heterozygosity.

If this interpretation is correct, then it follows that undesirable qualities are inherited as well as desirable, and that in order to secure this hybrid vigour, it is necessary that the individuals used for the production of the first cross shall be as excellent as may be and that the good qualities of the two shall be, as far as is possible, complementary. The qualities that are concerned are not necessarily those of form and structure but are physiological, concerned with the kind and rate of functional activity, and so it is that hybrid vigour, as great as that which results from the crossing of different species or breeds, can follow the crossing of different families or strains of one and the same variety or breed. The breeder who keeps his family lines distinct can, by appropriate matings, secure all the hybrid vigour he seeks, without calling on the aid of other stocks.

Since for the production of hybrid vigour the qualities of the two parties must be compensatory and complementary, it follows that all matings cannot be expected to yield it. Experimentation alone can decide whether a particular mating will be attended by hybrid vigour in the offspring. Since it is the pooling of qualities that leads to hybrid vigour, and since breeding implies the assortment and redistribution of these qualities among the offspring, it follows that the further breeding of the first cross can lead to reduction in general sturdiness. The mule has kept its reputation because in the great majority of cases it is infecund, incapable of producing functional ova or sperm. Without the purebred there cannot be the crossbred of any worth. The first cross, deliberately bred for a definite commercial purpose, must not be used for further breeding.

Conclusion.—In the future all intelligent essays in animal breeding will be directed by a few and simple principles. New characters will not be created by the professional scientist, at least not yet, and new breeds, when made, will be nothing more than fresh combinations of already existing characters, called into being by the economic or other requirements of society. A new breed of this kind will be fashioned out of an already existing breed by continued and careful selection in the desired direction far more often than by hybridization involving two or more recognized breeds. The problem for the breeder and for the biologist is not that of making new breeds but of raising the average production of the breeds already existing. In every breed of farm animals the average production is far below that of outstanding individuals, and the task before the agriculturalist is that of defining the economic upper limit of productivity (since all production of this kind is physiologically expensive) and of reducing the margin between the average and the best.

Thus it appears that the principles of animal breeding are as follows:

(1) The definition of the ideal type in relation to habitat and destiny.

(2) The definition of the shortcomings of already existing types in relation to the ideal.

(3) The improvement of the already existing types by continued selection in the direction of the ideal.

(4) The selection of animals for breeding as far as possible on the basis of the progeny test; individual merit and pedigree also to be considered.

(5) The system of inbreeding to be followed to as great an extent as is practicable.

(6) The system of outcrossing to be practised for the production of special types for purposes other than for further breeding.

ANIMAL EXTRACTS. Many substances used in therapeutics are derived from the animal kingdom; the majority are obtained from the animals themselves, only a few, such as honey and wax, being obtained through the activity of a member of the animal kingdom. The most common animal extracts are adrenalin, beeswax, cod liver oil, gelatin (or gelatine), honey, insulin, lanolin (or lanoline), lard, pepsin, spermaceti, suet, thyroid gland extract (qq.v.) and cantharidin (see CANTHARIDES). Others widely used are the following:

Pituitary extract, prepared from the posterior lobe of the pituitary body of the sheep. It is a circulatory stimulant which acts within a minute or so of injection and has a somewhat prolonged action; it is therefore of great use in cardiac failure. It is also used in obstetric medicine instead of ergot to promote uterine contraction. It is never given by the mouth. **Testicular extract** or orchic substance is given for sterility and premature sterility, arrested growth, and various neuroses. **Ovarian extract** is used in amenorrhoea and dysmenorrhoea, in vicarious menstruation and certain other diseases; it is useful in nervous symptoms at the change of life and after removal of the ovaries. **Pancreatic solu-**

tion, prepared from the fresh pancreas of the pig, contains at least four ferments, the most important of which is trypsin, which acts in an alkaline medium, converting proteids into peptones. Many pancreatic foods are on the market and are often of use to invalids and those whose digestions are weak. *Ox-gall*, obtained from the gall bladder of bullocks, is sometimes used as a purgative in cases in which there are indications of a deficient secretion of bile.

ANIMAL FAT: see GLYCERIDES.

ANIMAL HEAT. Under this heading is discussed the physiology of the temperature of the animal body.

The higher animals have within their bodies certain sources of heat, and also some mechanism by means of which both the production and loss of heat can be regulated. This is conclusively shown by the fact that both in summer and winter their mean temperature remains the same. But it was not until the introduction of thermometers that any exact data on the temperature of animals could be obtained. It was then found that local differences were present, since heat production and heat loss vary considerably in different parts of the body, although the circulation of the blood tends to bring about a mean temperature of the internal parts. Hence it is important to determine the temperature of those parts which most nearly approaches to that of the internal organs. Also for such results to be comparable they must be made in the same situation. The rectum gives most accurately the temperature of internal parts, or in women and some animals the vagina, uterus or bladder. Occasionally that of the urine as it leaves the urethra may be of use. More usually the temperature is taken in the mouth, axilla or groin.

Warm and Cold Blooded Animals.—By numerous observations upon men and animals, John Hunter showed the essential difference between the so-called warm-blooded and cold-blooded animals to lie in the constancy of the temperature of the former, and the variability of the temperature of the latter. Those animals high in the scale of evolution, birds and mammals, have a high temperature almost constant and independent of that of the surrounding air, whereas among the lower animals there is much variation of body temperature, dependent entirely on their surroundings. There are, however, certain mammals which are exceptions, being warm-blooded during the summer, but cold-blooded during the winter when they hibernate. But it must be remembered there is no hard and fast line between the two groups. Also, from work recently done by J. O. Wakelin Barratt, it has been shown that under certain pathological conditions a warm-blooded (homoiothermic) animal may become for a time cold-blooded (poikilothermic). He has shown conclusively that this condition exists in rabbits suffering from rabies during the last period of their life, the rectal temperature being then within a few degrees of the room temperature and varying with it. He explains this condition by the assumption that the nervous mechanism of heat regulation has become paralysed. The respiration and heart-rate being also retarded during this period, the resemblance to the condition of hibernation is considerable. Again, Sutherland Simpson has shown that during deep anaesthesia a warm-blooded animal tends to take the same temperature as that of its environment. He demonstrated that when a monkey is kept deeply anaesthetized with ether and is placed in a cold chamber, its temperature gradually falls, and that when it has reached a sufficiently low point (about 25°C. in the monkey), the employment of an anaesthetic is no longer necessary, the animal then being insensible to pain and incapable of being roused by any form of stimulus; it is, in fact, narcotized by cold, and is in a state of what may be called "artificial hibernation." Once again this is explained by the fact that the heat-regulating mechanism has been interfered with. Similar results have been obtained from experiments on cats. In man, injury of the spinal cord, as in gun-shot wounds, may abolish the heat regulating portion of the lower part of the body, in which case the body temperature can only be maintained constant by artificial means. These facts—with many others—tend to show that the power of maintaining a constant temperature has been a gradual development, as Darwin's theory of evolution suggests, and that anything that inter-

feres with the due working of the higher nerve-centres puts the animal back again, for the time being, on to a lower plane of evolution.

Variations in the Temperature of Man and Some Other Animals.—As stated above, the temperature of warm-blooded animals is maintained with but slight variation. In health under normal conditions, the temperature of man varies between 36°C. and 38°C., or if the thermometer be placed in the axilla, between 36.25°C. and 37.5°C. In the mouth the reading would be from .25°C. to 1.5°C. higher than this; and in the rectum some .9°C. higher still. The temperature of infants and young children has a much greater range than this, and is susceptible of wide divergencies from comparatively slight causes.

Of the lower warm-blooded animals, there are some that appear to be cold-blooded at birth. Kittens, rabbits and puppies, if removed from their surroundings shortly after birth, lose their body heat until their temperature has fallen to within a few degrees of that of the surrounding air. But such animals are at birth blind, helpless and in some cases naked. Animals who are born when in a condition of greater development can maintain their temperature fairly constant. In strong, healthy infants a day or two old the temperature rises slightly, but in that of weakly, ill-developed children it either remains stationary or falls. The cause of the variable temperature in infants and young immature animals is the imperfect development of the nervous regulating mechanism.

The average temperature falls slightly from infancy to puberty and again from puberty to middle age, but after that stage is passed the temperature begins to rise again, and by about the 80th year is as high as in infancy. A diurnal variation has been observed dependent on the periods of rest and activity, the maximum ranging from 10 A.M. to 6 P.M., the minimum from 11 P.M. to 3 A.M. Sutherland Simpson and J. J. Galbraith have recently done much work on this subject. In their first experiments they showed that in a monkey there is a well marked and regular diurnal variation of the body temperature, and that by reversing the daily routine this diurnal variation is also reversed. The diurnal temperature curve follows the periods of rest and activity, and is not dependent on the incidence of day and night; in monkeys which are active during the night and resting during the day, the body temperature is highest at night and lowest through the day. They then made observations on the temperature of animals and birds of nocturnal habit, where the periods of rest and activity are naturally the reverse of the ordinary through habit and not from outside interference. They found that in nocturnal birds the temperature is highest during the natural period of activity (night) and lowest during the period of rest (day) but that the mean temperature is lower and the range less than in diurnal birds of the same size; that the temperature curve of diurnal birds is essentially similar to that of man and other homoiothermal animals, except that the maximum occurs earlier in the afternoon and the minimum earlier in the morning. Also that the curves obtained from rabbit, guinea-pig and dog were quite similar to those from man. The mean temperature of the female was higher than that of the male in all the species examined whose sex had been determined.

Meals sometimes cause a slight elevation, sometimes a slight depression—alcohol seems always to produce a fall. Exercise and variations of external temperature within ordinary limits cause very slight change, as there are many compensating influences at work, which are discussed later. Even from very active exercise the temperature does not rise more than one degree, and if carried to exhaustion a fall is observed. In travelling from very cold to very hot regions a variation of less than one degree occurs, and the temperature of those living in the tropics is practically identical with those dwelling in the Arctic regions.

Limits Compatible with Life.—There are limits both of heat and cold that a warm-blooded animal can bear, and other far wider limits that a cold-blooded animal may endure and yet live. The effect of too extreme a cold is to lessen metabolism, and hence to lessen the production of heat. Both katabolic and anabolic changes share in the depression, and though less energy

is used up, still less energy is generated. This diminished metabolism tells first on the central nervous system, especially the brain and those parts concerned in consciousness. Both heart-beat and respiration-number become diminished, drowsiness supervenes, becoming steadily deeper until it passes into the sleep of death. Occasionally, however, convulsions may set in towards the end, and a death somewhat similar to that of asphyxia takes place. Cats are unable to survive when the rectal temperature is reduced below 16°C. At this low temperature respiration becomes increasingly feeble, the heart-impulse usually continues after respiration ceases, the beats becoming very irregular, apparently ceasing, then beginning again. Death appears to be mainly due to asphyxia.

The heart has great powers of surviving reductions of temperature. It is said that in Siberia the hearts of animals which have been buried hours or days have, when excised and perfused, been made to beat.

Too high a temperature hurries on the metabolism of the various tissues at such a rate that their capital is soon exhausted. Blood that is too warm produces dyspnoea and soon exhausts the metabolic capital of the respiratory centre. The rate of the heart is quickened, the beats then become irregular and finally cease. The central nervous system is also profoundly affected, consciousness may be lost, and the patient falls into a comatose condition, or delirium and convulsions may set in. All these changes can be watched in any patient suffering from an acute fever. The lowest limit of temperature that man can endure depends on many things, but no one can survive a temperature of 45°C. (113°F.) or above for very long. Mammalian muscle becomes rigid with heat rigor at about 50°C., and obviously should this temperature be reached the sudden rigidity of the whole body would render life impossible. H. M. Vernon has recently done work on the death temperature and paralysis temperature (temperature of heat rigor) of various animals. He found that animals of the same class of the animal kingdom showed very similar temperature values, those from the Amphibia examined being 38.5°C., Fishes 39°, Reptilia 45° and various Molluscs 46°. Also in the case of pelagic animals he showed a relation between death temperature and the quantity of solid constituents of the body, *Cestus* having lowest death temperature and least amount of solids in its body. But in the higher animals his experiments tend to show that there is greater variation in both the chemical and physical characters of the protoplasm, and hence greater variation in the extreme temperature compatible with life.

Regulation of Temperature.—The heat of the body is generated by the chemical changes—those of oxidation—undergone not by any particular substance or in any one place, but by the tissues at large. The ultimate source of heat is the food which is oxidized in the body and the oxidation of which liberates the same quantity of energy as it would do if burned. This energy is dissipated either in mechanical work or as heat—the latter forming by far the greater proportion. Not all foods have the same heat producing or caloric value. The ordinary heat production of a person is made up somewhat as follows, per day:

Protein	120 grams	=	480,000 calories.
Fat	100 "	=	940,000 "
Carbohydrate	330 "	=	1,385,000 "
			2,805,000 calories.

Wherever destructive metabolism (katabolism) is going on, heat is being set free. When a muscle does work it also gives rise to heat, and if this is estimated it can be shown that the muscles alone during their contractions provide far more heat than the whole amount given out by the body. Also it must be remembered that the heart—itsself a muscle—never resting, must give rise to no inconsiderable amount of heat. From this it is clear that the larger proportion of total heat of the body is supplied by the muscles. These are essentially the "thermogenic tissues." Next to the muscles as heat generators come the various secretory glands, especially the liver, which appears never to rest in this respect. Also a certain amount of heat is produced by the changes which the food undergoes in the alimentary canal before it really enters the body.

But heat is also continually being lost. And it is by the constant modification of these two factors (1) heat production and (2) heat loss, that the constant temperature of a warm-blooded animal is maintained. Heat is lost to the body through the faeces and urine, respiration, conduction and radiation from the skin, and by evaporation of perspiration. The following are approximately the relative amounts of heat lost through these various channels (different authorities give somewhat different figures): faeces and urine about 3, respiration about 20, skin (conduction, radiation and evaporation) about 77. Hence it is clear that the chief means of loss are the skin and the lungs. The more air that passes in and out of the lungs in a given time, the greater the loss of heat. And in such animals as the dog, which do not perspire easily by the skin, respiration becomes far more important. The dog when lying in the sun adopts a special type of very rapid shallow respiration, whereby the proportion of air passing into and out of the respiratory passages is great as compared with that which invades the deeper portions of the lung—hence he can evaporate large quantities of aqueous vapour without working out a corresponding quantity of aqueous vapour. It is claimed that by this means his blood may be reduced to a temperature lower than normal in which case the stimulus must be sought in the temperature of the skin, rather than that of the brain.

But for man, the great heat regulator is undoubtedly the skin, which regulates heat loss by its vasomotor mechanism, and also by the nervous mechanism of perspiration. Dilation of the cutaneous vascular areas leads to a larger flow of blood through the skin and so tends to cool the body and vice versa. Also the special nerves of perspiration can increase or lessen heat loss by promoting or diminishing the secretions of the skin. There are great difficulties in the exact determination of the amount of heat produced, but there are certain well-known facts in connection with it. A larger living body naturally produces more heat than a smaller one of the same nature, but the surface of the smaller, being greater in proportion to its bulk than that of the larger loses heat at a more rapid rate. Hence to maintain the same constant bodily temperature, the smaller animals must produce a relatively larger amount of heat.

Food temporarily increases the production of heat, the rate of production steadily rising after a meal until a maximum is reached from about the 6th to the 9th hour. If sugar be included in the meal the maximum is reached earlier; if mainly fat, later. Muscular work very largely increases the production of heat, and hence the more active the body the greater the production of heat.

BY COURTESY OF PROF. R. O. DU BOIS

FIG. 1.—THE DU BOIS HEIGHT-WEIGHT CHART FOR DETERMINING THE SURFACE AREA OF MAN IN SQUARE METRES FROM WEIGHT IN KILOGRAMS (WT.) AND HEIGHT (HT.). THE FORMULA IS: AREA (SQ. IN.) = WT. .425 X HT. .725 X 71.84

Under basal conditions, *i.e.*, at rest in bed before breakfast, the quantity of heat given out is proportional to the surface of the body. The latter may be calculated approximately from a knowledge of the height and weight of the person according to Du Bois' "Height and Weight Chart" fig. 1. A heat loss of 40 calories per square metre of surface per hour is regarded as the normal basal metabolic rate. In miners the heat loss may

become on the average of 24 hours over 100 calories per square metre of body surface per day. Such persons have developed the power of losing water from the skin to a very high pitch. An average loss of water of over 3 lb. per hour on a five-hour shift has been registered in the case of coal miners.

But all the arrangements in the animal economy for the production and loss of heat are themselves probably regulated by the central nervous system, there being a thermogenic centre—situated above the spinal cord, and according to some observers in the optic thalamus. (See also NUTRITION.)

ANIMAL MAGNETISM: see HYPNOTISM.

ANIMAL PSYCHOLOGY, the study of the behaviour of the lower animals with a view to ascertaining their mentality. Animal Psychology is a part of Comparative Psychology (*q.v.*), and its special interest consists in the light which it throws on the development of the human mind, and especially on human instincts and impulses.

ANIMALS, DOMESTICATION OF. Animals are captured and tamed by man either as pets or for use, and some of the more familiar domestic animals, such as the dog and the cat, come under both headings.

Pets.—The keeping of pets with no ulterior object is practically universal wherever attractable animals are found. The Australians have never domesticated any animal, but they like pets. They catch rats, opossums, wallabies, bandicoots, frogs or young birds for playthings. They tie them up at night to prevent their escape, and as they are not fed or cared for, they soon die. Cassowaries, with wings clipped, are allowed to wander about the camp and pick up scraps, and young opossums or wallabies often learn to be self supporting. The dingo is usually caught young and tied by its leg until it is reconciled to its surroundings. In America many tribes tame animals and birds in this way.

From such unpromising experiments the taming and domestication of animals made a start, and the subsequent steps are easy to follow, the last being conscious breeding by man, by which he creates new species or varieties for his use and pleasure. In the first stage, that of toleration, there is no definite ownership or "purposive control" by man. The animals are free, but are encouraged and protected in consideration of services rendered. Next comes domestication, the private or collective ownership of animals trained to be of use to their masters, such as cattle, horses and domestic animals in general. In the further stage of artificialization, "provisional breeding or stirpiculture," animals are bred and reared for special purposes. The influence of religion or magic, either in animal cults or totemism, has probably been an important factor in the domestication of certain animals. The reverence paid to sacred animals tends to establish friendly relations with it; animal cults are connected with many domestic animals, and especially with cattle, and the origin of domestic cattle is traced to this source. Thus totemism has been claimed as the starting point of domestication. The totem animal, being venerated, protected and encouraged, acquired confidence and became domesticated.

History.—But neither the "pet" theory nor the "totem" theory of the origin of domestication is of universal application, and no definite evidence of the domestication of the more familiar animals is to be expected. Owing to the existence of wild species,

all used for food, the determination of the date of domestication is difficult.

Dog.—The dog, a sociable animal, is of use to man at his lowest culture stage, assisting the hunter in tracking, chasing, attacking, and capturing the game. The origin of the domestic dog is uncertain. At least four different types were in existence in Europe (Portugal, Switzerland and Denmark) and Asia (Anau) in the Stone Age. America also has several varieties of dogs.

Cat.—The cat, like the dog, probably domesticated itself, and is usually derived from Egypt, where it was known about 2000 B.C. The importance of grain-growing in that region has suggested that the reverence paid to it was based on its services to the agriculturist. It is found wild in Europe, Asia, and Africa. It is recorded in Greece about 1500 B.C. and in Rome, much later, possibly not much before the Christian era. According to popular belief, it was introduced into Britain by the Romans.

Cattle, Goats, Sheep, Pigs.—Domestication of cattle, goats, sheep and pigs was an established feature of the Neolithic age in Western Europe and of the earlier—but still Neolithic—settlements of Anau in Russian Turkestan and of Susa in Mesopotamia in the 3rd and 4th millennia, suggesting that Asia may have been the area where the domestic species and their culture originated, and whence they were derived. In arid regions such as desert oases like Anau, animals are forced into proximity to man, and there, in drier seasons, they could survive in desperate cases only by the sacrifice of their independence.

Ass, Horse.—The ass was probably domesticated at about the same time both by the pre-dynastic Egyptians and by the Sumerians of Mesopotamia, but the origin of the domesticated horse, for which there is no such early evidence, is a more difficult problem. At least four varieties were known to, and probably hunted for food, by palaeolithic man. Its domestication appears to have been fairly late, and though its remains occur in the Swiss lake dwellings there is little evidence for its use in western Europe until the Bronze Age. It is characteristic of the steppe culture of Asia, and spread thence both east and west, and is referred to in early Japanese traditions, which contain no mention of the dog. The story of the horse in America is more clear, as the native animal was extinct in prehistoric times and was unknown to the Americas before the coming of the Spaniards who followed Columbus. Stray horses soon multiplied on the plains of both North and South America, and were so quickly caught and tamed by the Indians that horse culture was established among many of the tribes long before they came in direct contact with Europeans.

Reindeer.—The reindeer shows interesting grades of domestication. The American caribou was always hunted and never domesticated, though recent experiments indicate that this was not impracticable. The eastern Siberian tribes such as the Chukchi own huge herds of wild deer, used mainly for slaughter and barter; the Tungus, farther west, train the deer for sledge work, and do most of the carrying trade of the tundra; the Lapps in north-west Europe and to a certain extent the Samoyeds to the east alone have domesticated the reindeer, using it both for transport and for milking.

Influence of Domestication.—The existence of domesticable species has undoubtedly influenced the uneven civilization of the world. Europe and Asia were well supplied. North America, at the time of the discovery, had none except the dog. The Peruvian had domesticated the llama and its relative the paco or alpaca for flesh, wool, and transport, and the ccoy or guinea-pig for food and cheap sacrifice. Australia, owing to its early separation from the rest of the world, had no domestic species at all, if we except the questionable dingo, and this lack contributed largely to the backward condition of its inhabitants. The domestication of cattle in the early history of man made a settled life possible for him, with an assured food supply and the acquisition of property—the identity of cattle and property in early times being illustrated in the word "pecunious" (Lat. *pecus*, cattle).

ANIMALS, EXPERIMENTS ON. The making of experiments on the lower animals for the purpose of advancing medi-

cal knowledge is in some countries unrestricted; in others it is restricted by law.

METHODS EMPLOYED AND EXPERIMENTS

The Existing Law in Britain.—The present law relating to experiments on animals was passed in 1876. At that time bacteriology was in its infancy, bio-chemistry was unborn and the majority of these experiments were physiological. The Act, therefore, was drafted with a view to physiology. At the present time the vast majority of animal experiments are inoculations in researches upon bacterial diseases or cancer. Every experiment must be made in a registered place open to government inspection. But inoculation experiments are sometimes permitted in non-registered places, for the immediate study of outbreaks of disease, or if circumstances render it impracticable to use a registered place. Every experiment must be made under a licence.

Most experiments are made not under a licence alone, but under a licence *plus* one or more certificates, and the wording and working of these certificates must be clearly understood, because it is over them that the question arises as to the amount of pain inflicted by these experiments. Under the licence alone, the animal must be kept under an anaesthetic during the whole of the experiment; and "if the pain is likely to continue after the effect of the anaesthetic has ceased, or if any serious injury has been inflicted on the animal," it must be killed forthwith under the anaesthetic. Thus, under the licence alone, it is impossible to make an inoculation; for the experiment consists, not in the introduction of the needle under the skin, but in the observation of the results of the inoculation. A guinea-pig inoculated with tubercle cannot be kept under an anaesthetic till the disease appears. The disease is the experiment, an experiment made without an anaesthetic, and not authorized by the licence alone.

To remove these disabilities, the Act empowers the Secretary of State for Home Affairs to allow certificates to be held with the licence. They must be recommended by two signatures, and the home secretary attaches to licences and certificates such endorsements and restrictions as he thinks fit. The Act is administered with great strictness, under a careful system of enquiry and reference.

The certificates are distinguished as A, B, C, E, EE and F. Certificate D, which permitted the testing, by experiments, of "former discoveries alleged to have been made," has fallen into disuse. Certificate C permits experiments to be made in illustration of lectures. They must be made under the provisions contained in the Act as to the use of anaesthetics. Certificates E and EE permit experiments on dogs or cats; Certificate F permits experiments on horses, asses or mules. These certificates are linked with Certificate A (which allows experiments to be made without anaesthesia) or Certificate B (which permits the keeping alive of the animal after the initial operation).

Thus, in Great Britain experiments on animals may only be performed (1) by a duly licensed person; (2) in an approved and registered place of research; (3) for an approved specific purpose; (4) on specific kinds of vertebrate animals (the Act not applying to invertebrates); (5) within a specified period or on a specified number of animals; (6) the word "experiment" is not allowed to cover more than one animal.

The United States.—In the United States attempts have repeatedly been made since about 1890 to obtain special legislation limiting experiments on animals. Responsible heads of departments in medical schools and research institutes have consistently opposed these attempts. They have argued that there has been no demonstrated abuse of animals for experimental purposes in the laboratories of the United States, that if abuse should appear the existing laws against cruelty would suffice to correct it, and that until the general law is proved inadequate special legislation is unnecessary. Up to 1929 no special legislation had been passed restrictive of animal experimentation for purposes of scientific discovery. About 1910 a system of rules governing the treatment of animals used for research was drawn up by a committee of the American Medical Association. These rules have been adopted by corporate vote in practically all institutions engaged in medical

research. They constitute a mode of self-regulation of investigators engaged in animal experimentation. In each instance the director of the laboratory is made responsible for the character of the experiments performed in his laboratory.

Classes of Experiment.—From this brief account of the chief provisions of the Act we come to consider the general method of experiments on animals. The animals most used for inoculations without anaesthetics are mice, rats, guinea-pigs and rabbits. The act of inoculation is not in itself painful. A small area of the skin is carefully shaved and cleansed; that it may be aseptic, the hypodermic needle is sterilized and the method of hypodermic injection or of vaccination is the same as it is in medical practice. In a few instances cultures of micro-organisms have been made in the anterior chamber of the eye, by the introduction of a needle behind the cornea. This might be thought painful, but cocaine renders the surface of the eye wholly insensitve. Many operations of ophthalmic surgery are done under cocaine alone, and the anterior chamber of the eye is so far insensitve that a man may have blood or pus (*hypopyon*) in it, and hardly be conscious of the fact. The results of inoculation are in some cases negative, in others positive; the positive results are, in the great majority of cases, not a local change, but a general infection which may end in recovery, or in death.

The diseases thus induced may, in many cases, fairly be called painless—such as septicaemia in a mouse, snake-venom in a rat, the growth of cancer grafts beneath the skin of inoculated rats or mice, and malaria in a sparrow. Rabbits affected with rabies do not suffer in the same way as dogs and some other animals, but become subject to a painless kind of paralysis. It is probable that animals kept for inoculation have, on the whole, less pain than falls to the lot of a like number of animals in a state of nature or in subjection to work: they are well fed and sheltered, and escape the rapacity of larger animals, the inevitable cruelties of sport, and the drudgery and sexual mutilation that man inflicts on the higher domestic animals.

We now come to experiments made under Certificate B (which must be linked with Certificate EE for any experiment on a dog or a cat). Three instances may be given: an operation on the brain, removal of part or the whole of a secreting gland, and the establishment of a fistula. It is to be noted that, for these and similar operations, profound anaesthesia and the strict observance of asepsis are necessary for the success of the experiment: the operation could not be performed without anaesthesia; and the experiment would fail if the wound suppurated. These operations are such as are daily performed in surgery.

As to operations on the brain we know from human cases that the surface of the brain is not sensitive. Therefore the removal or destruction of a portion of the surface of the brain, or the division of some tract of central nervous tissue, though it may entail some loss of power or of control, does not cause pain. Tension within the cranial cavity, as in cases of cerebral tumour or cerebral abscess, may indeed cause great pain; and, if the aseptic method fails in an experiment, inflammation and tension ensue: in that case the animal must be killed.

The removal of part or the whole of a secreting gland (e.g., the thyroid, the spleen, the kidney) is performed by the same methods, and with the same precautions, as in human surgery. Profound anaesthesia, and strict asepsis are fundamental. The skin over the part to be removed must be shaved and carefully cleansed for the operation; the instruments, sponges and ligatures must be sterile, not capable of infecting the wound; and when the operation is over, the wound must be carefully closed with sutures, and left to heal under a proper surgical dressing.

The establishment of a fistula, again, is an operation practised in large numbers of surgical cases. The stomach, the gall-bladder and the large intestine are opened for the relief of obstruction, and kept open, either for a time or permanently, according to the nature of the case. Under anaesthesia, the organ that is to be opened is exposed through an incision made through the structures overlying it and is secured in the wound by means of fine sutures. When it has become adherent there, it is opened by an incision; no anaesthetic is needed for this purpose, because these

internal organs are so unlike the skin in sensitiveness that an incision is hardly felt: the patient may say that he "felt a prick," or he may be wholly unconscious that anything has been done. A fistula thus established is not afterwards painful, though there may be some discomfort now and again.

SCIENTIFIC RESULTS TRACEABLE TO ANIMAL EXPERIMENT

Here a summary account alone can be given; fuller information must be sought under the different diseases, etc. It must also be remembered that not man alone, but animals also owe a great debt to them. Great epizootic diseases like anthrax, swine-fever, chicken-cholera, distemper, pleuro-pneumonia, glanders, Texas cattle fever, blackleg, tuberculosis in cattle have killed yearly millions of animals, and have been brought under better control by these experiments. The advantages that have been obtained by man may be arranged under two heads—(A) Physiology, (B) Pathology, Bacteriology and Therapeutics.

(A) PHYSIOLOGY

Passing over the fundamental knowledge gained in this way on the heart and circulation by William Harvey, Stephen Hales and John Hunter we have learned by animal experiment to measure accurately the work done by the heart and, by studying the manner in which this work is affected by different conditions, we can increase or diminish it according to the needs of the organ. Experiments in that part of physiology which deals with muscle and nerve have thrown light on the wonderful process of "compensation" by which a diseased heart is able to keep up a normal circulation. Similarly, the flow of chyle along the lacteals and thoracic duct, the part played by the stomach, the liver, the pancreas and the intestinal glands, respectively, in digestion, the growth of bone, the functions of certain parts of the brain, of the sympathetic system, of nerves (including their regeneration after injury), reflex action, the mechanism of respiration, the influence of endocrine glands, the action of vitamins have all depended upon animal experiment. Indeed it is impossible to think of any advance in physiological knowledge which is not directly or indirectly traceable thereto. Even the recent isolation of insulin, in itself a matter of chemistry, was led up to by observation that removal of the pancreas in dogs is followed by permanent diabetes.

(B) PATHOLOGY, BACTERIOLOGY AND THERAPEUTICS

As examples of knowledge obtained in this sphere by animal experiment the following instances may be named:—

(1) **Inflammation.**—Every change in the tissues during inflammation—the slowing of the blood stream in the capillary vessels, the escape of the leucocytes through their walls into the surrounding tissues, the stagnation of the blood in the affected part—all these were observed in such transparent structures as the web or the mesentery of the frog, the bat's wing, or the tadpole's tail, irritated by a drop of acid, or a crystal of salt, or a scratch with a needle. It was in the course of observations of this kind that Wharton Jones observed the rhythmical contraction of veins, and Waller and Cohnheim observed the escape of the leucocytes, *diapedesis*, through the walls of the capillaries. From these simple experiments under the microscope arose all our present knowledge of the minute processes of inflammation. Later came the work of Metchnikoff and others, showing the importance of *diapedesis* in immunity.

(2) **Suppuration and Wound Infection.**—Lister's work on antiseptics and its modern extension—asepsis—depend upon knowledge gained in investigations of bacterial diseases produced experimentally in animals under diverse conditions.

(3) **Anthrax.**—In France between 1882 and 1893 over 3,000,000 sheep and nearly 500,000 cattle were inoculated against this disease by the preventive method discovered by Pasteur. The average mortality, before vaccination, for the whole of France, was 10% in sheep and 5% in cattle; with vaccination it fell to 0.94% in sheep and 0.34% in cattle. In rouget (swine-measles) the effect of preventive inoculation was even more

striking, the mortality falling from an average of 20% to one of 1.45%. (Chamberland, *Ann. de l'Inst. Pasteur*, March 1894.)

(4) **Tuberculosis.**—To animal experiments is owed our knowledge of the nature of tuberculosis prior to discovery of the specific bacillus, proof that *B. tuberculosis* is the causal organism, the importance of associated suppurative micro-organisms in determining the type of the disease, and the use of tuberculin for detection of tuberculous cows.

(5) **Diphtheria.**—Proof that *B. diphtheriae* is the causal organism, immunization of animals against the disease, introduction of treatment by diphtheria antitoxic serum, discovery of the Schick preventive method of inoculation.

(6) **Tetanus.**—The bacterial nature of tetanus and the mode of action of tetanotoxin were discovered and an antitoxic serum was prepared which is of great value as a preventive agent in animals and man. In the laboratory curative effects can be obtained by administration of the serum which, so far, are not paralleled in the natural disease.

(7) **Rabies (hydrophobia).**—To Pasteur's animal experiments we owe the whole process of preventive inoculation with emulsions of brain and spinal cord of rabbits artificially infected with rabies.

(8) **Cholera.**—The "comma bacillus" was discovered in 1883 and ten years later preventive inoculation was first carried out on an extensive scale by Haffkine in India.

(9) **Bubonic Plague.**—*B. pestis* was discovered in 1894 and subsequently the entire history of the disease, its relation to the rat-flea, the variations in type to which it is liable and the methods of preventive inoculation and serum treatment were worked out.

(10) **Typhoid and Paratyphoid Fevers.**—The bacteriology of these began in 1880 when *B. typhosus* was discovered. *B. paratyphosus* C was found in Mesopotamia during the World War. Protective inoculation against typhoid carried out in 1896 by Almroth Wright and Semple quickly showed its value. In the British Army during the World War a typhoid vaccine alone was used at first, but later a mixed vaccine of *B. typhosus*, *B. paratyphosus* A and *B. paratyphosus* B. The results were a triumphant success. To animal experiment must also be ascribed discovery of agglutination as a means of diagnosis (Widal's reaction).

(11) **Malta or Mediterranean Fever.**—Discovery of the causal micro-organism, of an immunizing serum for treatment and tracing of the origin of the disease to the milk of infected goats by means of agglutination reactions.

(12) **Epidemic Meningitis (cerebro-spinal).**—Discovery of the meningococcus by inoculation experiments and separation of different types by agglutination methods. Introduction of serum treatment for the disease whereby its mortality has been reduced to about one-half.

(13) **Malaria.**—The bulk of our knowledge of this disease, including the life history of the malarial parasite and the elaboration of preventive measures founded thereupon, was obtained by observations on man, but was led up to by the study of closely similar blood parasites occurring in birds.

(14) **Yellow Fever.**—Discovery of a special mosquito (*Stegomyia*) which conveys the disease from man to man. Preparation of a specific anti-serum.

(15) **Sleeping Sickness.**—Experiments on animals have proved that this disease is due to specific parasites carried by tse-tse flies from man to man. By measures taken to obviate this method of infection the incidence of the disease has been reduced.

(16) **Infantile Paralysis.**—Flexner of the Rockefeller Institute has proved, by experiments on animals, the infective nature of this disease and its transmissibility by inoculation.

(17) **Myxoedema.**—Evidence that removal of the thyroid gland in animals produces the disease and that subsequent feeding with thyroid gland or thyroid extract effects a cure.

(18) **The Action of Drugs.**—A long list has been more or less fully worked out, of which the following are the chief: Aconite, amyl nitrite and the nitrites in general, belladonna, mem-

bers of the barbitone series, calcium chloride, cocain, chloral, digitalis, ergot, insulin, morphia, salicylic acid, strophanthus, the chief diuretics and diaphoretics.

(19) **Snake Venom.**—Experiment has shown that animals can be immunized against many times the fatal dose of the venom of various poisonous snakes and that the serum of an animal immunized against one type of snake venom is effective against other types. Anti-venomous serum is now used in many parts of the world on man and domestic animals for snake bite. (See *VIVISECTION.*) (S. PA.; W. S. L.-B.)

ANIMAL SOCIOLOGY. The distinctive note of an animal society is that a number of individuals of the same species act together as a unity, combining their efforts in defence or in attack or in work. Thus a troop of monkeys, a beaver village, a herd of horses or cattle, a pack of wolves, a colony of viscachas, a rookery, a flock of cranes, may serve as illustrations of corporate life, which is in a sense more than the sum of its parts. The mere living together of a multitude, like mites in the cavern of a cheese or rabbits in a warren, does not constitute a society; the criterion is some capacity for acting coherently and harmoniously as a unit. In a large society form like an ant-hill there may be a number of simultaneously active units, each a corporate body. When beavers unite their efforts to make a canal through a large island in the middle of a river, or when rooks combine against a hawk, there is a distinctive social note. The degree of the sociality varies greatly; thus baboons show more concerted action than prairie dogs, and beavers than bisons, and rooks much more than parrots. Considered from the individual point of view, social life among animals implies some measure of self-subordination to communal activity and interests. The contrast is a solitary individualistic mode of life, an each-for-himself régime. There is no warrant for ethical imputations, which do not seem more than incipiently relevant among animals. An otter is self-sufficient as effectively as the beaver is co-operative; the two ways of living are suited for different conditions of existence. Another feature of the social and gregarious mode of life is some alleviation of the individual struggle for existence. To some extent, the communal life serves as a shield for types of individual that could not otherwise stand alone. This may go so far as to allow of the prolonged survival of non-viable types, such as queen termites, and of individuals that cannot find food for themselves, like the drones of the beehive.

There are two main groups of animal societies—(a) those mainly on an intelligent basis, as among monkeys, horses, cattle, elephants, beavers; and (b) those mainly on an instinctive basis, as among ants, bees, wasps, and termites. But this is not a hard and fast dichotomy, for beavers show much instinctive behaviour and bees may be occasionally intelligent. Social birds show both instinctive and intelligent behaviour. At the same time, there is an obvious contrast between a society mainly intelligent and a society mainly instinctive. If the concept of corporate unity among near kin be extended downwards in the animal kingdom, it naturally leads to colonies of physically united individuals, as in hydroids, sea-pens, reef-corals, Polyzoa and compound Tunicates. The occurrence of dimorphism or polymorphism is of interest, since this division of labour naturally leads from aggregates like a reef-coral to genuine integrates, like the Portuguese Man-of-War, a multitudinous colony of polymorphic individuals that can swim as if it were one animal. These physically continuous colonies, formed by repeated budding, might almost be termed vegetative societies—for many individuals act as one, there is physiological self-subordination, and there is a *modus vivendi* found for individual types which, in some cases, could not survive in isolation.

Advantages of Social Life.—The advantages of some form of social, communal, gregarious or co-operative life may be summed up: (1) Many small animals, with no strong individual foothold, become safe and indeed irresistible in their societies, as ants well show. (2) Operations impossible for a single individual may be effected by corporate effort, as when several ants combine to bring large booty to the nest, or when wolves surround their prey, or when pelicans form a living seine-net for fish. (3) There may

be an economization of energy, at a high level, when one wild goose relieves another as leader of the flying phalanx, or, at a low level, when a number of ants reduce the loss of heat by huddling into a living ball. (4) Economy is enhanced when it is backed by division of labour, as among the specialized castes of ants and termites. (5) There is an opportunity for forming permanent products, such as ant-hill, termitary, bee-hive and beaver-dam, which doubtless operate as evolutionary factors. (6) Although one must postulate more or less kin-sympathy or the like in the initiation of a society form, a *milieu* will be increasingly developed in which the psychical aspect has more chance to find expression than in the solitary mode of life. The social *milieu* is one in which there is likely to be a fostering of wits and kindly feelings, besides such anticipations as play and artistic products. The idiosyncrasies illustrated in ant-communities are manifold, such as keeping slaves, guests, and the analogues of domestic animals. In some cases, it must be admitted, the shield of the society allows of the survival of strange phenomena bordering on the pathological. Thus in a slave-making community of ants, the dominant caste may require to be not merely foraged for, but literally fed, by the so-called slaves. Some of the Coleopterous and Dipterous guests of termites pass into a practically diseased condition called physogastry, in which the abdomen becomes swollen, the wings drop off, the insects become quite or almost blind. According to Wheeler this is the Nemesis of life in the termitary with its close humid atmosphere, its cramped quarters, its narrow passages, and the superabundance of carbohydrate food. But the aegis of animal society is more often progressive than retrogressive. It is not maintained that the individual stimulations towards expertness and sympathy have entailed results which accumulate as part of the racial endowment. That is as it may be (see *HEREDITY*). What is suggested here is merely that the social *milieu* is one in which germinal variations in the direction of, say, better brains and stronger sympathies will have an increased chance to survive. (7) By itself, as most fundamental, must be ranked the shield that a society affords to its members, giving them a firmer foothold in the struggle for existence, and allowing variations and experimental initiatives to be tested without being subject to too severe external selection.

Pre-Conditions of Sociality.—If the social way of life has all the advantages indicated, the question naturally arises why it has not been adopted by a larger number of animal types. The answer is to be found in the pre-conditions which make sociality possible. First, there must be some capacity for kin-sympathy and fineness of brain. Fishes may swim in shoals but there is hardly any hint of integration. Mites may congregate in millions but they have not the brain for sociality. Secondly, there must be the possibility of large numbers. A small society is almost a contradiction in terms. Therefore an animal society demands either prolific multiplication, as in ants and bees and still more in termites, or a long period of reproductivity, as in elephants. Thirdly, the habits of the animal must be congruent with life in a community. Thus among spiders, which are highly evolved types, there are only two or three social species. Solitary hunters, such as otters, are precluded from social life. Thus we see that while the social way of living is very advantageous, and brings indirect as well as direct rewards, it is far from being open to all.

Social Activities.—The activities of an animal society find diverse expression:

(A) Some may be grouped as communal enterprises. There may be united defence, as of wasps against an intruder, wild cattle against a large beast of prey, rooks against a hawk. Or there may be concerted attack, as when small birds mob a hawk or an owl, or a pack of weasels attack a dog. There may be co-operation in securing food, as when monkeys raid an orchard, or wolves surround their victim, or pelicans in a half circle close in upon fishes. In some cases there is combined action in making a shelter, like a termitary, or a well-housed store, as in a hive. A beaver's dam or canal, necessarily a co-operative achievement, is accessory to transport and storing.

In many cases the corporate endeavour has considerable subtlety, as in the slave-making raids of the Amazon ants, in which

the existing slaves may play a major part in recruiting others of the same species. Migration is often a social phenomenon, with detailed features of interest, such as flying in a V-shaped formation, so familiar in wild geese but seen in many other birds. Gregarious nesting as in rooks is hardly in itself social, but the social note is sounded in the composite nest of Republican Birds. Some social activities of animals are very striking, such as the wars of some kinds of ants and the social plays of others; the drilling manoeuvres of penguins and their games; the choruses of some birds; and the community singing of the Howling Monkeys.

(B) Other expressions of social life are to be found in the evolution of means of communication. This is clearest, though not most primitive, in the case of sound-signals. The utterance of a kin-call may bring other members of the society to the rescue; a sentinel's danger-cry may save a crowd. But from such simple beginnings there is a gradual rise to the use of many "words" with specialized significance, sounds that come to be associated with particular stimuli, feelings, experiences, or even objects. In many cases, however, the medium of communication is by odours. Thus in the life of bees a part is played by the "queen-odour" and the "sting-odour." There is a visual and olfactory communication when a worker that has found a particular treasure of nectar executes on her return to the hive a specialized dance on the honeycomb and also betrays by the scent the kind of flower she had just visited. In the antennary communications between ants there is a mingling of tactile and olfactory stimuli. In many mammals there are often gestures as well as words.

(C) Social life is expressed also in what may be called customs, conventions or traditions, as the case may be. These have a mental or subjective aspect, namely certain instincts or predispositions with their attendant feelings; and they have an objective aspect in permanent products, like the termitary, and in the organization of the society, as in the existence of polymorphic castes. It seems possible to distinguish a hereditary compulsion, such as prompts the feeding of the hungry, and an environmental compulsion imposed by the nature of the home, the food, and the division of labour. A crowded hive must be kept clean; the soldier termites must be fed by the workers. But in some cases it seems necessary to postulate a social compulsion, remotely analogous to public opinion, such as that expressed in the gradual cold-shouldering of the drones in a bee-hive, accentuated into fatal stinging towards the end of the season.

It is a convention that the appeal of a hungry ant must be met by a neighbour who is full; that a cry for help must be answered; that stores must not be privately pillaged; that, after a certain stage, there must be no thieving of nest-sticks in a rookery. Very suggestive, in an instinctive community, is the graduated apprenticeship of worker-bees. Very suggestive in an incipient intelligent community is that among chimpanzees a cry of protest may arouse an uproar of indignation in the whole company. But it is not possible as yet to do more than illustrate the activities that find expression in the social life of animals.

Different Forms of Family.—The sociological study of animals must include an inquiry into the different forms of family. Many animals have abundant progeny, and yet show no hint of family life. This is generally the case with animals which illustrate the spawning method of multiplication, as in fishes that liberate eggs and sperms somewhat fortuitously in the water. Similarly in frogs, the spawn in the ditch is left to itself, and the tadpoles that hatch out from the clump do not remain together in any coherent way. It is noteworthy, however, that in expression of different constitutions and in adaptation to different conditions of life, types that are structurally not remote from one another may exhibit very different relations as regards their offspring. The starfish *Luidia* is credited with producing two hundred million eggs in a year, and could hardly be expected to have a family circle; and yet Müller's starfish carries its comparatively large eggs about until the development is completed. Miniatures of this species are sometimes seen clambering on the body of the mother—obviously the beginning of family life.

Four types of family occur among animals: (1) The typical bi-parental family is that in which both parents remain for some time in helpful company with their offspring. According to Reichenow, a band of twenty or thirty gorillas may consist of five families—each with a father, a mother and a number of offspring. In the Common Wren (*Troglodytes troglodytes*) both parents share the family duties and may use the old nest as a shelter in winter, not for themselves alone, but for a number of young birds as well. In some ducks and geese the offspring remain for the greater part of a year under the protection and tutelage of their parents. Even in some pronouncedly predatory mammals, such as lion and fox, the father stands by the mother and the family for a long time, helping not only in defence, but in providing food. At a much lower level, in a few fishes, such as *Labrus* and *Eupomotis*, there is the beginning of a bi-parental family.

(2) The second kind of family is maternal, where the mother takes sole charge. Thus the female spider may not only carry the developing eggs in a silken cocoon, but may bear the hatched young ones on her back until they are able to fend for themselves. A hen with her chickens illustrates a maternal family under man's shield, but there are many similar instances among polygamous birds in wild conditions. Small herds of eight or more elephants are said to consist, in some cases at least, of a mother and her offspring, whose births have been spaced out over many years. This approaches a small society. A distinction, though not a hard and fast one, should be drawn between parental care before birth and helpful association afterwards. Thus while some female fishes (African cichlids) carry their few eggs in their mouth, some go farther, for there are instances of the young ones returning after they have been hatched and liberated. Some illustrations are startling; thus it is recorded of certain kinds of scorpions that the mother catches insects for her offspring and even prepares the food by tearing it into small pieces.

(3) The third kind of family is paternal, where the father takes sole charge. Remarkable paternal care is illustrated by the male Sea-Horse which carries the eggs in a ventral pouch, or the New Guinea *Kurtus* which carries them attached to a hook on the top of the skull, or the American Gaff-Topsail which carries them in his mouth,—a procedure that seems to involve fasting for about two months; but this is transcended by the nest-making male sticklebacks which guard the progeny for some time after they are hatched. The male *Arius* not only incubates the eggs in his mouth, but after the young ones are liberated opens his jaws for them to return when danger is imminent. The male of the American Bow-Fin mounts guard over a rough and ready "nest" that has been cleared among the waterweeds; and after the young are hatched and leave their cradle he shepherds them for about four months. This is the beginning of a simple kind of family life.

(4) There is a fourth type of animal family, approaching a small society, and that is the "children-family." It consists of an association of young animals of the same age, but the association is not helped by the presence of parents. It is said to be illustrated at various levels, e.g., by reindeer, certain cetaceans, some of the pythons, various fishes such as herring, and some caterpillars like those that form processions. But it is possible that these associations of young animals of the same age should be ranked as incipient societies rather than as families. In any case they must be considered by the comparative sociologist. The same may be said in regard to such phenomena as the property sense in some animals, the "territories" of some birds, the "preserves" of some predatory types, and the various relations of mates, such as monogamy and polygamy.

ANIMAL WORSHIP, an ill-defined term, covering facts ranging from the worship of the real divine animal, commonly conceived as a "god-body," at one end of the scale, to respect

for the bones of a slain animal or even the use of a respectful name for the living animal at the other end.

Classification.—Animal cults may be classified in two ways: (A) according to their outward form; (B) according to their inward meaning, which may of course undergo transformations.

(A) There are two broad divisions: (1) all animals of a given species are sacred; (2) one or a fixed number of a species are sacred. It is probable that the first of these forms is the primary one and the second in most cases a development from it due to (i.) the influence of other individual cults; (ii.) anthropomorphic tendencies; (iii.) the influence of chieftainship, hereditary, and otherwise; (iv.) annual sacrifice of the sacred animal and mystical ideas connected therewith; (v.) syncretism, due either to unity of function or to a philosophic unification; (vi.) the desire to do honour to the species in the person of one of its members, and possibly other causes.

(B) Cults may be classified according to their meaning under ten specific heads: (i.) pastoral cults; (ii.) hunting cults; (iii.) cults of dangerous or noxious animals; (iv.) cults of animals regarded as human souls or their embodiment; (v.) totemistic cults; (vi.) cults of secret societies, and individual cults of tutelary animals; (vii.) cults of tree and vegetation spirits; (viii.) cults of ominous animals; (ix.) cults, probably derivative, of animals associated with certain deities; (x.) cults of animals used in magic.

(i.) The pastoral type falls into two sub-types, in which the species (a) is spared and (b) sometimes receives special honour at intervals in the person of an individual.

(ii.) In hunting cults the species is habitually killed, but (a) occasionally honoured in the person of a single individual, or (b) each slaughtered animal receives divine honours.

(iii.) The cult of dangerous animals is due (a) to the fear that the soul of the slain beast may take vengeance on the hunter, (b) to a desire to placate the rest of the species.

(iv.) Animals are frequently regarded as the abode, temporary or permanent, of the souls of the dead, sometimes as the actual souls of the dead. Respect for them is due to two main reasons: (a) the kinsmen of the dead desire to preserve the good will of their dead relatives; (b) they wish at the same time to secure that their kinsmen are not molested and caused to undergo unnecessary suffering.

(v.) One of the most widely found modes of showing respect to animals is known as totemism (*see* TOTEMISM), but except in decadent forms there is but little positive worship.

(vi.) In secret societies we find bodies of men grouped together with a single tutelary animal; the individual, in the same way, acquires the nagual or individual totem, sometimes by ceremonies of the nature of the bloodbond.

(vii.) Spirits of vegetation in ancient and modern Europe and in China are conceived in animal form.

(viii.) The ominous animal or bird may develop into a deity.

(ix.) In certain instances the animals associated with certain deities are sacred because the god was originally conceived in the shape of an animal; but the god may have been appealed to for help and thus become associated with the animals from which he protected the crops, etc.

(x.) The use of animals in magic may sometimes give rise to a kind of respect for them, but this is of a negative nature.

BIBLIOGRAPHY.—*See* articles in *E.R.E.* and authorities quoted in Sir James Frazer, *Golden Bough* (3rd ed., 1909-12), and the full bibliography given in vol. xii.

ANIMATISM is the tendency of the primitive mind to regard and treat the inanimate, in so far as it is held to be sacred, as if it were animated—that is, alive and endowed with feelings and a will of its own. In imputing animatism to the savage, due

THE LION GODDESS SEKHET, AFTER A STATUE FOUND IN RUINS OF THE EGYPTIAN TEMPLES AT KARNAK

allowance must be made for the fact that he is largely unconscious of the theory underlying his practice. Thus when a Toda of the Nilgiri hills in India feeds his sacred cattle-bell with milk, the civilized observer might justly draw the inference that the bell was supposed somehow to enjoy the milk; and yet it would probably be the fact that a given Toda who carries out this act of respect is blindly following religious custom, and has never troubled his head to think whether the bell, which obviously cannot drink in the ordinary manner, can nevertheless in some miraculous way get much the same satisfaction out of the milk as could a man or a cat. The word animatism was coined by Marett in 1899 to mark off a distinguishable phase of belief concerning whatever is deemed sacred and as such becomes the object of religious or quasi-religious attention and behaviour. Marett pointed out that Sir E. B. Tylor, when in *Primitive Culture* (1871), chap. xi., he suggested the term animism (*q.v.*), in the sense of "the belief in spiritual beings," as a "minimum definition of religion," had already in a previous chapter on mythology (chap. viii.) used the word animism in a different sense, namely, as the "theory of the universal animation of nature." The latter meaning is thus different and ought to be kept clear of the former. Marett therefore proposes that a separate word "animatism" should be used to express it. He argues that the notion of being alive is logically distinct from and historically and psychologically more rudimentary than the notion of being associated with a spiritual or soul-like being. He is, however, for limiting the application of the notion in question more narrowly than Tylor, who imputes to the savage a tendency to imagine nature as universally animated or alive. For can there ever have existed a savage who was mentally incapable of regarding anything whatever, an ordinary stone for instance, as unalive? Does not even the baby soon learn to distinguish its nurse by her relatively arbitrary proceedings from the chair with its thoroughly wooden way of reacting to the baby's way of thumping it? On the other hand, if the chair creaked in a peculiar manner it might frighten the baby, and might thereupon pass over into the class of objects that act arbitrarily, such as nurse with her uneven temper, or pussy that sometimes purrs and sometimes scratches. So too, then, the savage tends to put the stone into another category if it behaves queerly—if it refuses to be chipped into shape and cuts his finger, or emerges in the midst of the rapids and upsets his canoe. Nay, it need not act queerly; it is enough if it seems about to do so by looking queer. Just so the hunted animal perceives danger lurking in every unusual sight, or sound, or smell. The savage, however, being mentally a long way in advance of the animal, has generalized the unusual in a dim fashion, and has words of the type of *mana* (*q.v.*) to connote in the unfamiliar object a power of affecting man for better or worse—mostly, perhaps, for worse—in ways that defeat reasonable expectation. Animatism is therefore limited to the attribution of life to the unfamiliar, since it is an exaggeration to say that there is no room within the savage mind for any apprehension of the unalive. Further, for the purposes of the comparative study of religion in all its phases, including the most rudimentary, the unfamiliar may be identified with the sacred—that which is positively *mana*, or instinct with power to help or hurt in an unusual degree, and negatively is *tabu* (*q.v.*), that is, not lightly to be approached. Correspondingly, a "pre-animistic" type of religious belief and observance is distinguished in which no animism is involved in Tylor's second sense of the recognition of soul or spirit with a being of its own, distinct from bodily substance. In this pre-animistic theory a question of minor importance is whether *mana* and *animatism* go strictly together—that is to say, whether whatever has wonder-working power must necessarily seem likewise alive. It is rather a doubtful point, seeing that *mana* is often treated as if it were transmissible or contagious, like electricity or the influenza; whereas to think of a man's life as extending to his belongings is perhaps not so natural or easy. As a matter of fact, however, magic is practised on a man's clothes or on the clippings of his hair or nails, or on his personal name, or in fact on anything that can be identified with the man so far as to call him up to mind and conjure up a sense of his real

presence, in the belief that thereby the man will be deprived of his very life. Thus life would seem on this vague view of it to be no less contagious than *mana*, one or the other being alike a sort of communicable energy. Now, because such energy is communicable, it does not follow that there are not appropriate centres at which it originates; just as a push started by one man in a row may make itself felt right down the line. Some objects, for instance, would appear to be intrinsically sacred in the eyes of the savage, while in the case of anything else the sacredness is but acquired by association with such things as are sacred in themselves. In particular, certain types of persons, medicine-men, kings, women, strangers and so on, are considered sacred in their own right; and in such cases their *mana* may very naturally be treated as much the same as their will-power—an energy that is bound up with such personal initiative as they display. Indeed, in any case the unfamiliar is bound to strike the mind that is in awe of it as more or less self-active, since it does the threatening and he knocks under to it. In all magical conflict the result depends on which of the two has the initiative; for if I see the wolf before he sees me he cannot cast his spell over me but slinks off powerless. Thus *mana* implies life as manifested in initiative; so that John Murphy in *Primitive Man: his Essential Quest* (1927) is fully justified in representing the content of the confused notion at the back of animatism by the triad, "power-life-will." Further, the body or external appearance in and through which such power-life-will is exerted forms part of the same complex; the driving force and its vehicle, the god and the god's car, not being yet held apart in thought. At the pre-animistic stage the mind takes in the live wire, but has not yet taken in that electricity is the live thing in the wire and the rest but consentient matter. Of course these distinctions are made by the civilized man for his own classificatory purposes. The savage is unaware of stages in his thought, nay, mostly of the very fact that he thinks at all; and he does not change gear with any noticeable jerk when he shifts by slow degrees to a higher plane of analytic consciousness. If, however, the student of comparative religion hopes to make anything of what William James has called the "big buzzing booming confusion" of dawning reflection about the sacred and divine, he must boldly differentiate certain leading types, and may well find "animatism" to be a convenient way of representing the most rudimentary type of all.

ANIMATO (Ital.), a musical term signifying that the piece or passage so marked is to be played with animation and spirit. "Con anima" and "con spirito" have the same meaning.

ANIMÉ, an oleo-resin (said to be so called because in its natural state it is infested with insects) which is exuded from the locust tree, *Hymenaea courbaril* (family Leguminosae), and other species of *Hymenaea* growing in tropical South America. It is of a pale brown colour, transparent, brittle, and in consequence of its agreeable odour is used for fumigation and in perfumery. It is allied to copal in its nature and appearance, and is much used by varnish-makers. The name animé is also given to Zanzibar copal (*q.v.*).

ANIMISM is derived from *anima*, "breath," which in Latin came to have the secondary sense of "soul," very much as did the equivalent word *spiritus*, whence our "spirit." Hence animism might stand for any doctrine having to do with soul or spirit and, later, with souls or spirits. The word was coined early in the 18th century by Georg Ernst Stahl to describe his philosophy of a world-soul. More recently, William McDougall in *Body and Mind: a history and a defence of Animism* (1911) has used it to designate the "interaction-theory" of mind as an independent factor co-operating with the brain, as opposed to the various versions of what has been nicknamed "a psychology without a soul." Animism, however, will always be chiefly known as the term in which Sir Edward Burnett Tylor in *Primitive Culture* (1st ed. 1871) summed up his account of the origin of religion. Among anthropologists Tylor's animistic theory of religion stood unchallenged for nearly 30 years.

Although to-day the Tylorian explanation of religious origins has to be taken as subject to various important qualifications, it remains of great value; while the help it afforded at the time of its first appearance to anthropological research alike in the study and in the field can hardly be exaggerated. A whole generation of students of primitive culture sat at Tylor's feet, and more especially those whose interest lay chiefly in the history of religion.

The Minimum Definition of Religion.—In what follows, then, Tylor's animistic hypothesis need be considered solely in so far as it claims to supply "a minimum definition of religion." On this view, religion begins with a soul or spirit and ends with a god; a god being historically an evolved spirit, or conversely, a spirit being a god in the making. For the "belief in spiritual beings" comprises, firstly, "souls of individual creatures, capable of continued existence after the death or destruction of the body"; and, secondly, "other spirits, upward to the rank of powerful deities."

Given the idea of soul, the rest follows by a sort of logical extension; seeing that "the ideas of souls, demons, deities and any other classes of spiritual beings, are conceptions of similar nature throughout, the conceptions of souls being the original ones in the series." Thus, in order to make clear the origin and whole subsequent development, all that is still required is to explain the origin of the belief in a soul. Tylor proceeds to do it thus: "It seems as though thinking men, as yet at a low level of culture, were deeply impressed by two groups of biological problems. In the first place, what is it that makes the difference between a living body and a dead one; what causes waking, sleep, trance, disease, death? In the second place, what are those human shapes which appear in dreams and visions?" He goes on to suggest that the answer to the first riddle seemed to these primitive thinkers to be that every one has a life-principle that causes his body to feel, think and act but is capable of leaving it; and the answer to the second riddle that every one has a phantom, which can also leave the body since it appears to others at a distance. Putting the two notions together, the life-principle and the phantom, they created the idea of the *anima* or "ghost-soul"—a separable life-principle with an unsubstantial, wraith-like form of its own. Now this is much more than a crude statement to the effect that the origin of religion is a belief in ghosts.

Herbert Spencer had not much reason on his side when he asserted that he had long before anticipated the Tylorian theory when he put forward the view that "the aboriginal god is the dead chief" (*Mind*, ii. 1877, 415 et seq. citing *Westminster Review*, 1854, 360 et seq.). For Tylor's point is not merely that visionary shapes are seen but likewise that the consciousness of being alive, of moving the body, of leaving it temporarily and so on, is associated with these shapes.

If we describe the Tylorian explanation as "the dream-theory of religion," as is sometimes done, though very inadequately, we must not, at any rate, forget that the argument embraces both these aspects of dream; and that the aspect in which a man is aware of himself as going away to a distance during sleep should at least be as strongly emphasized as the other one in which he seems to be visited by others from a distance. Moreover, Tylor would be the first to allow that in advanced religion when God is said to be a spirit the personality alone is insisted on; whereas the outward appearance, whether man-like, wraith-like or what not, is treated as little more than a matter of symbolic imagery.

So, too, philosophers, from Plato in the *Phaedo* onwards, have deduced the soul's self-existence and immortality from certain data of consciousness, the faculty of reason, the feeling of self-activity, the moral sense and so on; whereas they have ever tended to regard the appeal to so-called objective manifestations of the spiritualistic order as smacking of superstition. To return to the savage, the objection to Tylor's theory is not that it is defective as a piece of reasoning but that, on the contrary, it is much too rational a view for the human mind to have adopted at the very outset of its experience of religion. The modern psychologist utterly disbelieves in Tylor's "thinking men," who begin by conceiving an idea and thereupon proceed to mould their practice in accordance with it, and terms this the fallacy of intel-

lectualism—the error of subordinating action to thought instead of thought to action. Man always thinks while acting, and in some sense after acting, since the function of thought is to be rudder, not propeller—to direct, while impulse drives.

Modern Attitude.—The modern method, therefore, of conceiving the development of man's religious activity would be to presuppose that he was well on his way towards religion before he thought about it at all. Thus, supposing Tylor to be right in taking the ghost-soul to be the earliest notion in the animistic series, the modern way would be to try to find some already current activity—say, funeral custom—in connection with which the idea in question might have grown up, as being in the first instance effect rather than cause. If, for instance, the custom was, as the Australian natives sometimes did, to abandon for the time being their cave-shelter, leaving the corpse there, or possibly the sick or aged man about to die, it might well happen that food and weapons would be left at the side of the body. Whereupon, by a sort of justification after the event the definite idea might grow up of a life after death in which food and weapons were needed; though at first the impulse to leave such things with the body might be almost unreasoning, amounting perhaps to no more than a dread of going near it or removing anything in contact with it. Whatever be the value of such an illustration, there can be little doubt in regard to psychological method that the Tylorian theory of the origin of religion in the idea of soul tends to put the cart before the horse. When, in 1899, the pre-animistic theory was put forward in opposition to Tylor's account of the earliest type of religion (see ANIMATISM and MANA), this was chiefly the point at issue; while it was at the same time suggested that the notion first generated by reaction to the object of religious awe was something much vaguer than that of soul as distinct from body, namely, that of *mana*, or, so to speak, the bare notion of awfulness in action. On the other hand, in the previous year Andrew Lang in *The Making of Religion* (1st ed. 1908) had attacked Tylor's animistic theory of the origin of religion from another side. He brought forward numerous examples of what he called "high gods of low races" who seemed to have nothing of the *anima* about them, but to be more like "magnified non-natural men." There is certainly nothing wraith-like about such beings, who rather resemble glorified human beings such as were the Greek gods. Lang's suggestion as to the origin of such anthropomorphic theism, as it might be termed, was that the notion of a maker or creator of the world might be chiefly responsible for it. This explanation, however, which he put forward quite tentatively in the introduction to the second edition, is also somewhat open to the charge of intellectualism; and it is surely more probable that the respect felt for the great chief or medicine-man—the man with *mana*—might continue to attach to his memory and so generate gods of the anthropomorphic or "man-like" pattern.

Conclusion.—Primitive religion, on fuller investigation than was possible in Tylor's time, turns out to comprise many types of divine being that the savage does not bring under one idea at all unless it is simply that of being divine, that is to say, worshipful; his consciousness of their being worshipful growing out of the very fact that he worships them by impulse precipitated in custom. Thus the Tylorian animism hardly provides a basis for primitive religion, but at most will serve as a key to primitive theology. Undoubtedly, when religion has reached the stage of trying to put its ideas into order, a certain uniformity of doctrine is obtained by assuming a hierarchy of spiritual beings, gods and godlings, demons and fairies, goblins and ghosts, all of which are supposed to have enough in common in respect to their nature to be dealt with by man by methods no less fundamentally alike. Like the soul or mind of which a man is aware in himself, they belong to the unseen; whereas the seen, like a man's body, is but the outward manifestation of a purpose that is essentially spiritual; that is, comes forth from the unseen. Such a theory paves the way for the moralization of religion, because by interpreting that which excites awe and reverence as, whatever the physical manifestation may be, an expression of will at bottom, it makes it easier to reach the position of advanced religion which tends to sum up all the good will in the universe with which man can

commune and co-operate in the notion of a single and personal God.

Animism is especially prominent in the religions of certain regions, such as Indonesia and South America. For Indonesia see G. A. Wilken, *Het Animisme bij de Völker van der Indischen Archipel*; A. C. Kruyt, *Het Animisme in der Indischen Archipel*; "L'Animisme chez les Peuples de l'Archipel Indien," in *Melusine* (1886). For South America see E. im Thurn, *Among the Indians of Guiana*; R. Karsten, *The Civilization of the South American Indians* (1926). (R. R. M.)

ANIMUCCIA, GIOVANNI, Italian musical composer, was born at Florence in the last years of the 15th century. At the request of St. Filippo Neri he composed a number of *Laudi*, or hymns of praise, to be sung after sermon time, which have given him an accidental prominence in musical history, since their performance in St. Filippo's Oratory eventually gave rise (on the disruption of 16th century schools of composition) to some of the earlier forms of "oratorio." In 1555 Animuccia was appointed *maestro di capella* at St. Peter's, an office which he held until his death in 1571. He was succeeded by Palestrina, who had been his friend and probably his pupil. The manuscript of many of Animuccia's compositions is still preserved in the Vatican Library.

BIBLIOGRAPHY.—His chief published works were *Madrigali e Motetti a quattro e cinque voci* (Venice, 1548) and *Il primo Libro di Messe* (Rome, 1567). From the latter Padre Martini has taken two specimens for his *Saggio di Contrapunto*. A mass from the *Primo Libro di Messe* on the *canto fermo* of the hymn *Conditor alme siderum* is published in modern notation in the *Anthologie des maîtres religieux primitifs of the Chanteurs de Saint Gervais*.

ANIO, a river of Italy about 75 miles long; the principal tributary of the Tiber in its lower course. It rises in the limestone mountains east of Subiaco, and thence to Tivoli the road follows its narrow valley. The water of the river supplied Rome in ancient times (see AQUEDUCT), while the pure and copious springs which served for the ancient Aqua Marcia and Aqua Claudia, and still form the city's main supply, are in its valley. But the *praeceps* (hurrying) Anio of Horace has been transformed by hydro-electric power-plants for the supply of Rome, and the famous waterfalls at Tivoli (*q.v.*) will be largely curtailed. From Tivoli to its junction with the Tiber it pursues a winding course through the low ground, and formed an effective protection to Latium from the north.

See Colasanti, *L'Aniene* (well illustrated, Bergamo, 1906).

ANION, the constituent of an electrolyte (see ELECTROLYSIS) deposited at the anode (*q.v.*) by an electric current. When a molecule (*q.v.*) splits into electrically charged parts these are called *ions* (see IONIZATION). In the case of a liquid the negative ion is termed the *anion* and is non-metallic in character. It consists of one or more atoms carrying a definite number of negative electric charges (see ELECTRON, THE), this number being called its valency (*q.v.*); e.g., the chlorine ion (Cl⁻) and the group NO₂ are both monovalent anions, while the group SO₄ is a divalent anion. (See also CATION.)

ANISE (*Pimpinella Anisum*), an umbelliferous plant found in Egypt and the Levant, and cultivated on the continent of Europe for medicinal purposes. The officinal part of the plant is the fruit, which consists of two united carpels, called a cremocarp. It is known by the name of aniseed, and has a strong aromatic taste and a powerful odour. By distillation the fruit yields the volatile oil of anise. Most of the oil of commerce, however, of which anethol is also the chief constituent, comes from *Illicium verum* (family Magnoliaceae, sub-family *Winteraeae*), indigenous in north-east China, the star-anise of liqueur makers. It receives its name from its flavour, and from its fruit spreading out like a star. The anise of the Bible (Matt. xxiii. 23) is *Anethum* or *Peucedanum graveolens*; i.e., dill (*q.v.*).

ANJAR, a fortified town of India and the capital of a district of the same name in the native State of Cutch in the presidency of Bombay. The country is arid and is supplied with water by well irrigation. The town is situated nearly 100 m. from the Gulf of Cutch. In 1921 the population was 13,510. The town and district

of Anjar were ceded to the British in 1816, but in 1822 were transferred to the Cutch Government in consideration of an annual money payment which was subsequently remitted.

ANJOU, the old name of a French territory representing the ancient Gallic State of the *Andes*, re-organized as the Roman *civitas* of the *Andecavi*, and preserved as an administrative district under the Franks with the name first of *Pagus*, then of *comitatus*, or countship of Anjou. This countship, nearly identical with the ecclesiastical diocese of Angers, occupied the greater part of what is now the department of Maine-et-Loire. It was bounded on the north by the countship of Maine, on the east by that of Touraine, on the south by that of Poitiers and by the Mauges and on the west by the countship of Nantes.

From the outset of the reign of Charles the Bald, the integrity of Anjou was seriously menaced by a two-fold danger: from Brittany and from Normandy. Lambert, a former count of Nantes, after devastating Anjou in concert with Nominé, duke of Brittany, had by the end of the year 851 succeeded in occupying all the western part as far as the Mayenne. This principality was occupied, on his death, by Erispoé, duke of Brittany; by him it was handed down to his successors, in whose hands it remained till the beginning of the 10th century. Meanwhile the Normans were ravaging the country, and towards 861, Charles the Bald entrusted it to Robert the Strong (*q.v.*), but he unfortunately met with his death in 866 in a battle against the Normans at Brissarthe. Hugh the Abbot succeeded him in the countship of Anjou as in most of his other duties, and on his death (886) it passed to Odo (*q.v.*), the eldest son of Robert the Strong, who, on his accession to the throne of France (888), probably handed it over to his brother Robert. In any case, during the last years of the 9th century, in Anjou as elsewhere the power was delegated to a viscount, Fulk the Red (mentioned under this title after 898), son of a certain Ingelgerius.

In the second quarter of the 10th century Fulk the Red had already usurped the title of count, which his descendants kept for three centuries. He was succeeded first by his son Fulk II. the Good (941 or 942-c. 960), and then by Fulk's son, Geoffrey I. *Grisegonelle* (c. 960-987), who inaugurated a policy of expansion, aiming at the extension of the boundaries of the ancient countship and the reconquest of those parts of it which had been annexed by the neighbouring states; for, though western Anjou had been recovered from the dukes of Brittany since the beginning of the 10th century, in the east all the district of Saumur had fallen into the hands of the counts of Blois and Tours. Geoffrey succeeded in making the count of Nantes his vassal, and in obtaining from the duke of Aquitaine a grant of the district of Loudun. His son Fulk III. Nerra (*q.v.*) (987-1040) was confronted on his accession by a coalition of Odo I., count of Blois, and Conan I., count of Rennes. The latter having seized upon Nantes, of which the counts of Anjou held themselves to be suzerains, Fulk Nerra came and laid siege to it, routing Conan's army at Conquereuil (June 27, 992) and re-establishing Nantes under his own suzerainty. Then turning against the count of Blois, he established a fortress at Langeais, a few miles from Tours, from which, thanks to the intervention of the king, Hugh Capet, Odo failed to oust him. On the death of Odo I., Fulk seized Tours (996); but King Robert the Pious turned against him and took the town again (997). In 1016 Odo II. of Blois was utterly defeated at Pontlevoy, and a few years later, while Odo was besieging Montboyau, Fulk surprised and took Saumur (1026). Finally, the victory gained by Geoffrey Martel (*q.v.*) (1040-60), the son and successor of Fulk, over Theobald III., count of Blois, at Nouy (Aug. 21, 1044), assured to the Angevins the possession of the countship of Touraine. At the same time, continuing in this quarter the work of his father, Geoffrey succeeded in reducing the countship of Maine to complete dependence on himself. During his father's life-time he had been beaten by Gervais, bishop of Le Mans (1038), but now (1047 or 1048) succeeded in taking the latter prisoner, and in spite of the concerted attacks of William, duke of Normandy, and Henry I., king of France, he was able in 1051 to force Maine to recognize his authority.

On his death (Nov. 14, 1060) there was a dispute as to the

succession. Having no children he had bequeathed the countship to his eldest nephew, Geoffrey III. the Bearded, son of Geoffrey, count of Gâtinais, and of Ermengarde, daughter of Fulk Nerra. But Fulk le Réchin, brother of Geoffrey the Bearded, who had at first been contented with an appanage consisting of Saintonge and the *châtellenie* of Vihiers, having allowed Saintonge to be taken in 1062 by the duke of Aquitaine, took advantage of the general discontent aroused in the countship by the unskilful policy of Geoffrey to make himself master of Saumur (Feb. 25, 1067) and

BY COURTESY OF THE FRENCH BUREAU OF TRAVEL

THE FORTRESS AT CHINON, AN IMPORTANT STRONGHOLD FOR THE MEDIAEVAL RULERS OF ANJOU, OVERLOOKING THE MODERN TOWN THAT LIES ON THE BANKS OF THE VIERNE

Angers (April 4) and cast Geoffrey into prison at Sablé. Compelled by the papal authority to release and restore him, he soon renewed the struggle, beat Geoffrey near Brissac and shut him up in the castle of Chinon (1068). In order, however, to obtain his recognition as count, Fulk IV. Réchin (1068-1109) had to carry on a long struggle with his barons, to cede Gâtinais to King Philip I., and to do homage to the count of Blois for Touraine. On the other hand, he was successful on the whole in pursuing the policy of Geoffrey Martel in Maine: after destroying La Flèche, by the Peace of Blanchelande (1081), he received the homage of Robert, son of William the Conqueror, for Maine. Later, he upheld Elias, lord of La Flèche, against William Rufus, king of England, and on the recognition of Elias as count of Maine in 1100, obtained for Fulk the Young, his son by Bertrade de Montfort, the hand of Eremburge, Elias's daughter and sole heiress.

Fulk V. the Young (1109-29) succeeded to the countship of Maine on the death of Elias (July 11, 1110); but this increase of Angevin territory came into such direct collision with the interests of Henry I., king of England, who was also duke of Normandy, that a struggle between the two powers became inevitable. In 1112 it broke out, and Fulk, being unable to prevent Henry I. from taking Alençon and making Robert, lord of Bellême, prisoner, was forced, at the treaty of Pierre Pecoulée, near Alençon (Feb. 23, 1113), to do homage to Henry for Maine. In revenge for this, while Louis VI. was overrunning the Vexin in 1118, he routed Henry's army at Alençon (Nov.), and in May 1119 Henry demanded a peace, which was sealed in June by the marriage of his eldest son, William, with Matilda, Fulk's daughter. William having perished in the wreck of the "White Ship" (Nov. 25, 1120), Fulk, on his return from a pilgrimage to the Holy Land (1120-21), married his second daughter Sibyl, at the instigation of Louis VI., to William Clito, son of Robert Courteuse, and a claimant to the duchy of Normandy, giving her Maine for a dowry (1122 or 1123). Henry I. managed to have the marriage annulled, on the plea of kinship between the parties (1123 or 1124). But in 1127 a new alliance was made, and on May 22, at Rouen, Henry I. betrothed his daughter Matilda to Geoffrey the Handsome, son of Fulk, the marriage being celebrated at Le Mans on June 2, 1129. Shortly after, on the invitation of Baldwin II., king of Jerusalem, Fulk departed to the Holy Land, married Melisinda, Baldwin's daughter and heiress, and succeeded to the throne of Jerusalem (Sept. 14, 1131). His eldest son, Geoffrey IV. the Handsome or "Plantagenet," succeeded him as count of Anjou (1129-51). From the first he tried to profit by his marriage, and after the death of Henry I. (Dec. 1, 1135), laid the foundation of the conquest of Normandy by a series of cam-

paings: about the end of 1135 or the beginning of 1136 he entered that country and rejoined his wife, the countess Matilda, who had received the submission of Argentan, Domfront and Exmes. Recalled into Anjou by a revolt of his barons, he returned to the charge in Sept. 1136 with a strong army, but after a few successes was wounded in the foot at the siege of Le Sap (Oct. 1) and had to fall back. In May 1137 began a fresh campaign in which he devastated the district of Hiémois (round Exmes) and burnt Bazoches. In June 1138, with the aid of Robert of Gloucester, Geoffrey obtained the submission of Bayeux and Caen; in October he devastated the neighbourhood of Falaise; finally, in March 1141, on hearing of his wife's success in England, he again entered Normandy. Many towns surrendered; in 1144 he entered Rouen, and received the ducal crown in its cathedral. Finally, in 1149, after crushing a last attempt at revolt, he handed over the duchy to his son Henry, who received the investiture at the hands of the king of France.

Meanwhile, the counts were strengthening their authority at home. Of Fulk the Young we know only a few isolated facts and dates. Geoffrey the Handsome was eminently fitted to suppress the coalitions of his vassals, and on his death his son Henry found himself heir to a great empire, strong and consolidated, to which his marriage with Eleanor of Aquitaine (May 1152) further added Aquitaine.

On the death of King Stephen, Henry was recognized as king of England (Dec. 19, 1154). His brother Geoffrey, who had received as appanage the three fortresses of Chinon, Loudun and Mirebeau, tried to seize upon Anjou, on the pretext that, by the will of their father, all the paternal inheritance ought to descend to him, if Henry succeeded in obtaining possession of the maternal inheritance. On hearing of this, Henry marched against his brother, from whom in the beginning of 1156 he succeeded in taking Chinon and Mirebeau; and in July he forced Geoffrey to give up even his three fortresses in return for an annual pension. Henceforward Henry succeeded in keeping the countship of Anjou all his life; for though he granted it in 1168 to his son Henry, he absolutely refused to allow him to enjoy his power. After Henry II.'s death in 1189 the countship passed to his son Richard I. of England, but on the death of the latter in 1199, Arthur of Brittany (born in 1187) laid claim to the inheritance, which ought, according to him, to have fallen to his father Geoffrey, fourth son of Henry II., in accordance with the custom by which "the son of the eldest brother should succeed to his father's patrimony." Supported by Philip Augustus of France, and William des Roches, seneschal of Anjou, he managed to enter Angers (April 18, 1199) and obtain recognition as count of Anjou, Maine and Touraine, for which he did homage to the king of France. Philip Augustus having deserted Arthur by the treaty of Le Goulet (May 22, 1200), John made his way into Anjou; and on June 18, 1200 was recognized as count at Angers. In 1202 he refused to do homage to Philip Augustus, who, in consequence, confiscated all his continental possessions, including Anjou, which was allotted by the king of France to Arthur. The defeat of the latter, who was taken prisoner at Mirebeau on Aug. 1, 1202, seemed to ensure John's success, but he was abandoned by William des Roches, who in 1203 assisted Philip Augustus in subduing the whole of Anjou. A last effort on the part of John in 1214 led to the taking of Angers (June 17) but broke down lamentably at the battle of La Roche-aux-Moines (July 2), and the countship was attached to the crown of France.

In Aug. 1246 King Louis IX. gave it as an appanage to his son Charles, count of Provence, soon to become king of Naples and Sicily (*see NAPLES*). On Aug. 16, 1290 his son, Charles II. married his daughter Margaret to Charles of Valois, son of Philip III. of France giving her Anjou and Maine for dowry, in exchange for the kingdoms of Aragon and Valentia and the countship of Barcelona. Charles of Valois at once entered into possession of the countship of Anjou, to which Philip IV., in Sept. 1297, attached a peerage of France. On Dec. 16, 1325, Charles died, leaving Anjou to his eldest son Philip of Valois, on whose recognition as king of France (Philip VI.) on April 1, 1328, the countship of Anjou was again united to the crown. On Feb. 17, 1332, Philip

VI. bestowed it on his son John the Good, who, when he became king (Aug. 22, 1350), gave the countship to his second son Louis I., raising it to a duchy in the peerage of France by letters patent of Oct. 25, 1360. Louis I., who became in time count of Provence and king of Naples (*see LOUIS I., king of Naples*), died in 1384, and was succeeded by his son Louis II., who devoted most of his energies to his kingdom of Naples, and left the administration of Anjou almost entirely in the hands of his wife, Yolande of Aragon. On his death (April 29, 1417) she took upon herself the guardianship of their young son Louis III., and in her capacity of regent defended the duchy against the English. Louis III., who also succeeded his father as king of Naples, died on Nov. 15, 1434, leaving no children. The duchy of Anjou then passed to his cousin René, second son of Louis II. and Yolande of Aragon, and king of Naples and Sicily (*see NAPLES*).

Unlike his predecessors, who had rarely stayed long in Anjou, René from 1443 onwards, paid long visits to it, and his court at Angers became one of the most brilliant in the kingdom of France. But after the sudden death of his son John in Dec. 1470, René, for reasons which are not altogether clear, decided to move his residence to Provence and leave Anjou for good (Oct. 1471). On July 22, 1474, he drew up a will by which he divided the succession between his grandson René II. of Lorraine and his nephew Charles II., count of Maine, but on his death (July 10, 1480) King Louis XI. annexed Anjou to the royal domain. King Francis I. again gave the duchy as an appanage to his mother, Louise of Savoy, by letters patent of Feb. 4, 1515. On her death, in Sept. 1531, it reverted to the king. In 1552 it was given by Henry II. to his son Henry who, on becoming king in 1574, conceded it to his brother Francis, duke of Alençon, at the treaty of Beaulieu near Loches (May 6, 1576). Francis died on June 10, 1584, and the vacant appanage definitively became part of the royal domain.

At first Anjou was included in the *gouvernement* of Orléanais, but in the 17th century it was made into a separate one. Saumur, however, and the Saumurois, for which King Henry IV. had in 1589 created an independent military governor-generalship in favour of Duplessis-Mornay, continued till the Revolution to form a separate *gouvernement*, which included, besides Anjou, portions of Poitou and Mirebalais. Attached to the *généralité* (administrative circumscription) of Tours, Anjou on the eve of the Revolution comprised five *élections* (judicial districts): Angers, Beaugé, Saumur, Château-Gontier, Montreuil-Bellay and part of the *élections* of La Flèche and Richelieu. Financially it formed part of the so-called *pays de grande gabelle* (*see GABELLE*), and comprised 16 special tribunals, or *greniers à sel* (salt warehouses): Angers, Beaugé, Beaufort, Bourgneil, Candé, Château-Gontier, Cholet, Craon, La Flèche, Saint-Florent-le-Vieil, Ingrandes, Le Lude, Pouancé, Saint-Remy-la-Varenne, Richelieu, Saumur. As regards purely judicial administration, Anjou was subject to the parlement of Paris; Angers was the seat of a presidial court, of which the jurisdiction comprised the *sénéchaussées* of Angers, Saumur, Beaugé, Beaufort and the duchy of Richelieu; there were besides presidial courts at Château-Gontier and La Flèche. When the Constituent Assembly, on Feb. 26, 1790, decreed the division of France into departments, Anjou and the Saumurois, with the exception of certain territories, formed the department of Maine-et-Loire.

BIBLIOGRAPHY.—(1) *Principal Sources*: The history of Anjou may be told partly with the aid of the chroniclers of the neighbouring provinces, in particular those of Normandy and of Maine (especially *Actus pontificum Cenomannis in urbe degentium*). For the 10th, 11th and 12th centuries there are some important texts dealing entirely with Anjou. The most important is the chronicle called *Gesta consulum Andegavorum* (*Chroniques des comtes d'Anjou*, published by Marchegay and Salmon, with an introduction by E. Mabille, Paris, 1856-71 collection of the *Société de l'histoire de France*). *See also* with reference to this text Louis Halphen, *Étude sur les chroniques des comtes d'Anjou et des seigneurs d'Amboise* (1906). The above may be supplemented by some valuable annals published by Louis Halphen, *Recueil d'annales angevines et vendômoises* (1903), (in the series *Collection de textes pour servir à l'étude et à l'enseignement de l'histoire*). For further details *see* Auguste Molinier, *Les Sources de l'histoire de France* (1902), ii. 1276-1310, and the book of Louis Halphen mentioned above.

(2) *Works*: The *Art de vérifier les dates* contains a history of

Anjou which is very much out of date. The 11th century only has been treated in detail by Louis Halphen, in *Le Comté d'Anjou au XI^e siècle* (1906), which has a preface with bibliography and an introduction dealing with the history of Anjou in the 10th century. For the 10th, 11th and 12th centuries, a good summary will be found in Kate Norgate, *England under the Angevin Kings* (1887). On René of Anjou, there is a book by A. Lecoy de la Marche, *Le Roi René* (1875). Lastly, the work of Célestin Port, *Dictionnaire historique, géographique et biographique de Maine-et-Loire* (1874-78), and its small volume of *Préliminaires* (including a summary of the history of Anjou), contain a mass of information concerning everything connected with Angevin history. (L. HA.)

ANKERITE, a member of the mineral group of rhombohedral carbonates. In composition it is closely related to dolomite, but differs from this in having magnesia replaced by varying amounts of ferrous and manganous oxides, the general formula being $\text{Ca}(\text{Mg,Fe,Mn})(\text{CO}_3)_2$. The colour is white, grey, or reddish. Ankerite occurs with chalybite in deposits of iron-ore.

ANKLAM or **ANCLAM**, Germany, 5m. above the mouth of the river Peene in the Kleines Haff, and 53m. N.W. of Stettin. Pop. (1925) 14,788. Anklam or Tanglim, originally a Slav fortress, joined the Hanseatic League in 1244. It was Swedish from 1648-76. It suffered in the Thirty Years' and Seven Years' Wars owing to its military importance, but still has its old walls and some quaint buildings. Foundries, mills and the making of agricultural machinery, furniture and sugar are carried on.

ANKLE or **ANGLE**, the joint which connects the foot with the leg (*see* JOINTS).

ANKOBER, a town in, and at one time capital of, the kingdom of Shoa, Abyssinia, 90 m. N.E. of Adis Ababa, in 9° 34' N., 39° 54' E., on a mountain about 8500 ft. above the sea. Ankober was made (c. 1890) by Menelek II. the place of detention of political prisoners. Pop. c. 3,000.

ANKOLE, a term used to designate a plateau of the Uganda Protectorate, British East Africa, and the people (Hima and Iro) occupying it. There has been little except linguistic assimilation here between the Hamitic intruders and the indigenous population. The former, known as Hima, and distinguished by fine features, small, almost Caucasian hands and feet and a light skin, comprise the autocracy. The latter, called Iro, a Hamitic word meaning slaves, with features characterized by rather projecting brow ridges, are the serfs or peasants. Both Hima and Iro wear skins and barkcloth but the latter are more careful about conventional decency, and an Iro married woman in addition to a number of skins worn round the waist must always wear heavy metal anklets. Apart from cicatrization they do not mutilate their bodies in any way. The Hima are cow-people and are subdivided into two classes, the rich and the poor. The former who own the cattle (a long-horned Galla type, sometimes humped owing to crossbreeding) are now sedentary, but the latter, who act as servants and herdsmen to the former (who provide them with wives and a few cattle) are nomads and move from place to place with the cattle. The Iro are purely agricultural and were rarely allowed to possess cattle as they do now; they have to supply the Hima with grain and beer. They are also the hunters of the tribe, as well as the smiths, potters (male and female) and carpenters, members of each craft being attached to the royal court, where they are generously rewarded for their services. War prisoners form a separate class of slaves, distinguished by the amputation of one or both ears.

The Hima live in collections of from ten to twenty houses inside a strong fence of thorn or euphorbia. There is a large courtyard and an inner fence secludes the living quarters, where there is a separate house for bachelors. The royal residence is a larger and more elaborate structure, including a house for pages, another for especially favoured wives, another for women who attend the ruler on his travels, a general house for the wives and a house for the wives who have borne children, all the houses being connected by covered passages. There would also be in the enclosure about a hundred other circular mud and wattle huts for women and attendants. The nomad herdsmen are content with much cruder huts and the bee-hive huts of the Iro are of much smaller dimensions and are scattered singly or in groups in or near plantations.

Polygamy is permitted but monogamy is customary. Marriage is regulated by totemic clans, which are subdivided into sub-clans distinguished by secondary and tertiary totems, and marriage is permitted within the three main clans if at least one totem differs. Princes formerly practised complete clan endogamy. There is an elaborate ceremonial of blood-brotherhood. The ruler's mother and sister have a special importance, and while among the Ganda the *kabaka's* sister has to marry her half-brother, here the *mugabe's* sister may marry whom she likes. Hima women are fattened almost to immobility before marriage, which takes place early in life. Pre-nuptial chastity is essential, followed by considerable post-nuptial license, both among Hima and Iro. Daughters must be married in order of age. Inheritance is by bequest, but the heir must be a son, who inherits the wives as well as the property. Intestate property goes to the ruler.

The Hima live mainly on milk, meat and beer; the Iro on their agricultural products and wild game. Their weapons are throwing spears, small oval shields with a central boss of wood or iron, bows and slings. The Iro shield is slightly larger and is often made of hippopotamus hide instead of basketwork, and they carry clubs instead of slings.

Offerings of beer, milk and cattle are made to the sacred royal drums, which are the only drums in the tribe, and are kept in a special enclosure, which is a sanctuary for malefactors. Music is provided by a primitive harp and by water jars filled to different levels. The Iro use square-shaped canoes on the lake, constructed of wooden boards laced together, but without the Ganda keel or prow.

The *mugabe* or ruler (who used to be called *mukama* like the Nyoro ruler) is the centre of social and political life. He holds all the tribal land in trust and distributes estates to the chiefs and theoretically all property is his. Cattle may not be sold to anyone outside the tribe without his permission and herdsmen may only kill bull-calves up to a given number. All land is free to the cattle-owners and their herdsmen, and the Iro may cultivate where they like, but are attached to cowmen as their agricultural workers, a chief retaining as many as three hundred. The *mugabe* is an absolute ruler with autocratic powers which he may delegate to chiefs. Next in importance to him is his minister called *nganzi* or "favourite." There are 16 districts presided over by chiefs called *bakungu* or *abamangi*, who are appointed by the *mugabe* on his accession, each with a different title and special duties and status. The chiefs are always pastoral. They settle disputes, keep peace and order, guard the royal cattle, and their sons act as pages at the *mugabe's* court. There are also inferior chiefs in each district who are almost independent of the *bakungu*. Pages who are too old for such service are appointed *galagwa*, a title which carries the rank of chief, are given estates, cows and serfs and form an autonomous community in each district. All taxation is in the hands of the *mugabe* who collects a percentage of cattle every year on all herds of 50 or more. The *mugabe* commits suicide by taking a special royal poison when too old or suffering from an incurable illness, and his widows are expected to commit suicide at his grave. The milk ceremonies are extremely important to the tribe and in them the *mugabe's* milk vessels play a dominant part.

There is no priestly caste or formulated religion. *Ruhanga*, the Creator, was probably an ancient hero or ruler and is revered with fourteen other sanctified kings, but neither these nor certain natural phenomena which are treated as divine, like *Omusisi* the Earthquake, have shrines or receive sacrifice. The ghosts or spirits of family ancestors are more important, and their religious eminence is recognized by family shrines, prayers and offerings. Spirits of dead rulers are supposed to enter lions. Rainmakers (*abaisi*) belong exclusively to the serf class, but they receive generous gifts not only from the Iro, but also from the Hima including the *mugabe* himself.

See Sir H. H. Johnston, *The Uganda Protectorate* (1902); J. Roscoe, *The Banyankole* (1923). (J. H. D.)

ANKYLOSIS or **ANCHYLOSIS**, a stiffness of a joint, the result of injury or disease. The rigidity may be complete or partial and may be due to inflammation of the tendinous or

muscular structures outside the joint or of the tissues of the joint itself. When the structures outside the joint are affected, the term "false" ankylosis has been used in contradistinction to "true" ankylosis, in which the disease is within the joint. When inflammation has caused the joint-ends of the bones to be fused together the ankylosis is termed *osseous* or complete. Excision of a completely ankylosed shoulder or elbow may restore free mobility and usefulness to the limb. "Ankylosis" is also used as an anatomical term, bones being said to ankylose when, from being originally distinct, they coalesce, or become so joined together that no motion can take place between them.

ANKYLOSTOMIASIS or **ANCHYLOSTOMIASIS** is also called helminthiasis, "miner's anaemia," and in Germany *Wurmkrankheit*. (See **HOOKWORM**.)

ANNA, BALDASARRE, Italian painter, who flourished during part of the 16th and 17th centuries, was born at Venice, probably about 1560, and seems to have been alive in 1639. He studied under Leonardo Corona, and completed several works left unfinished by him. The old guide-books and descriptions of Venice notice a considerable number of paintings by him. Scarcely any of these, however, have survived.

ANNA (Hindustani *Ana*), an Indian penny, the 16th part of a rupee. The term belongs to the Mohammedan monetary system (see **RUPEE**). There is no coin of one anna, but there are half-annas of copper and two-anna pieces of silver. The term anna is frequently used to express a fraction. Thus an Anglo-Indian speaks of two annas of dark blood (an octoroon), a four-anna (quarter) crop, an eight-anna (half) gallop.

ANNA AMALIA (1739–1807), duchess of Saxe-Weimar, daughter of Charles I., duke of Brunswick-Wolfenbüttel, was born at Wolfenbüttel on Oct. 24, 1739, and married Ernest, duke of Saxe-Weimar, 1756. Her husband died in 1758, leaving her regent for their infant son, Charles Augustus. She was a patroness of art and literature and attracted to Weimar many of the most eminent men in Germany. Wieland was appointed tutor to her son, and the names of Herder, Goethe, and Schiller shed an undying lustre on her court. In 1775 she retired into private life, her son having attained his majority. In 1788 she set out on a lengthened tour through Italy, accompanied by Goethe. She died on April 10, 1807. A memorial of the duchess is included in Goethe's works under the title *Zum Andenken der Fürstin Anna-Amalia*.

See F. Bornhak, *Anna Amalia, Herzogin von Saxe-Weimar-Eisenach* (1892).

ANNABERG, a town in the republic of Saxony, Germany, in the Erzgebirge, 1,894 ft. above the sea, 18 m. S. by E. of Chemnitz. Pop. (1925) 18,204. The Annenkirche (1499–1525) possesses fine sculptures and early 16th century works of art. Annaberg, together with the suburb of Buchholz, is the chief seat of the braid and lace-making industry in Germany, and makes cardboard boxes, buttons, silk goods, etc.; the industry was introduced here by Barbara Uttmann in 1561, and further developed by Belgian refugees, who settled here in 1590. The mining of tin, silver and cobalt has now ceased.

ANNABERGITE, a mineral consisting of a hydrous nickel arsenate, $\text{Ni}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$, crystallizing in the monoclinic system. Crystals are minute and capillary and rarely met with, the mineral occurring usually as soft earthy masses and incrustations. A fine apple-green colour is its characteristic feature. It was long known under the name nickel-ochre; the name annabergite being from Annaberg in Saxony, one of the localities of the mineral.

ANNA COMNENA, Byzantine historian, daughter of the Emperor Alexius I. Comnenus, was born on Dec. 1 1083. She was carefully trained in the study of poetry, science and Greek philosophy. She united with the Empress Irene in a vain attempt to prevail upon her father during his last illness to disinherit his son and give the crown to her husband, Nicephorus Bryennius. She then conspired to depose her brother after his accession; and when her husband refused to join in the enterprise, she exclaimed that "nature had mistaken their sexes, for he ought to have been the woman." The plot being discovered,

Anna forfeited her property and fortune. Shortly afterwards, she retired into a convent and employed her leisure in writing the *Alexiad*—a history, in Greek, of her father's life and reign (1081–1118), supplementing the historical work of her husband. It is rather a family panegyric than a scientific history. Anna died in 1148.

BIBLIOGRAPHY.—Editions in Bonn *Corpus Scriptorum Hist. Byz.*, by J. Schopen and A. Reifferscheid (1839–78), with Du Cange's valuable commentary; and Teubner series, by A. Reifferscheid (1884). See also C. Krumbacher, *Geschichte der byzantinischen Literatur* (2nd ed. 1897); Gibbon, *Decline and Fall*, ch. 48; Finlay, *Hist. of Greece*, iii. pp. 53, 128 (1877); P. ANNA LEOPOLDOVNA, sometimes called ANNA CARLOVNA (1718–1746), duchess of Brunswick, regent of Russia for a few months during the minority of her son Ivan, was the daughter of Catherine, sister of the empress Anne, and Charles Leopold, duke of Mecklenburg-Schwerin. In 1739 she married Prince Antony Ulrich of Brunswick-Wolfenbüttel, son of Ferdinand Albert, duke of Brunswick, and their son Ivan was adopted in 1740 by the empress and proclaimed heir to the Russian throne. A few days after the proclamation the empress died, leaving directions regarding the succession and appointing her favourite Ernest Biren, duke of Courland, as regent. Biren was detested by the Russian people, and Anna assumed the regency. In Dec. 1741, Elizabeth, daughter of Peter the Great, excited the guards to revolt, overcame the slight opposition that was offered, and was proclaimed empress. Ivan was thrown into prison, where he soon afterwards perished. Anna and her husband were banished to a small island in the river Dvina, where on March 18, 1746, she died in childbirth.

ANNALISTS, writers of annals (*Annales*, chronicles, properly year-books); a name commonly given to a group of Roman writers to whom is due the formation of the conventional history of Rome from the earliest times. It is alleged that from the beginning it was customary to keep a record of all important events; that these records, restored as far as possible after the Gaulish invasion, were continued down to the pontificate of P. Mucius Scaevola; and that the 80 books of the *Annales maximi* embodied the substance of them. In modern times, great and well-founded doubt has been expressed as to the age and accuracy of these supposed chronicles (*cf.* **ROMAN HISTORY: Authorities**). At all events, the oldest annalists, from the time of the Second Punic War, used such public records as they could find, supplementing them with family traditions and, in all probability, filling gaps largely from their own or their Greek preceptors' imaginations, since Rome seems to have been extraordinarily poor in sagas and myths of all kinds. In course of time a sort of orthodox pseudo-tradition grew up concerning the earliest history of Rome (*cf.* **EVANDER, ROMULUS**). The annalists may be divided into two groups, the earlier, from Fabius Pictor (*q.v.*) to Piso, being, on the evidence of Cicero (*de orat.*, ii. 53) very plain and undorned in style, while the later, mostly of the time of Sulla, were more literary and rhetorical. Caelius Antipater (*see* below) seems to mark the turning-point; he had, says Cicero, little learning and no great stylistic ability, but he polished his work as well as he could. Some of the chief names are as follows: Q. Fabius Pictor and L. Cincius Alimentus, contemporaries of Hannibal, who took the latter prisoner; both wrote histories of Rome from the foundation to their own day, and both wrote in Greek. M. Porcius Cato (*q.v.*) who wrote in Latin; L. Cassius Hemina, about 146 B.C.; L. Calpurnius Piso Censorius Fruci, consul 133 B.C. It is noteworthy that Livy thinks him less trustworthy than Fabius, and that he is often cited for details plainly fictitious (*cf.* **PRISO**). Of the later group Quintus Claudius Quadrigarius (about 80 B.C.) wrote a history, in at least 23 books, which began with the conquest of Rome by the Gauls and went down to the death of Sulla or perhaps later. He was freely used by Livy in part of his work (from the sixth book onwards). A long fragment is preserved in Aulus Gellius (ix. 13), giving an account of the single combat between Manlius Torquatus and the Gaul. His language was antiquated and his style dry, but his

work was considered important. Valerius Antias, a younger contemporary of Quadrigarius, wrote the history of Rome from the earliest times, in a voluminous work consisting of 75 books. He is notorious for his wilful exaggeration, both in narrative and numerical statements. Nevertheless, Livy at first made use of him as one of his chief authorities, until he became convinced of his untrustworthiness. C. Licinius Macer (died 66), who has been called the last of the annalists, wrote a voluminous work full of rhetoric and of authorities anything but certainly authentic. Having been convicted of extortion, he committed suicide (Cicero, *De Legibus*, i. 2, *Brutus*, 67; Plutarch, *Cicero*, 9).

The writers mentioned dealt with Roman history as a whole; some of the annalists, however, confined themselves to shorter periods. Thus, L. Caelius Antipater (about 120) limited himself to the Second Punic War. He was regarded as the most careful writer on the war with Hannibal, and one who did not allow himself to be blinded by partiality in considering the evidence of other writers (Cicero, *De Oratore*, ii. 12). Livy made great use of him in his third decade. Sempronius Asellio (about 100 B.C.) military tribune of Scipio Africanus at the siege of Numantia, composed *Rerum Gestarum Libri* in at least 14 books. As he himself took part in the events he describes, his work was a kind of memoirs. He was the first of his class who endeavoured to trace the causes of events, instead of contenting himself with a bare statement of facts. L. Cornelius Sisenna (110-67), wrote 23 books on the period between the Social War and the dictatorship of Sulla. His work was commended by Sallust (*Jugurtha*, 95), who, however, blames him for not speaking out sufficiently. Cicero remarks upon his fondness for archaisms (*Brutus*, 74, 259). Sisenna also translated the tales of Aristides of Miletus. The autobiography of Sulla may also be mentioned.

Peter, *Historicorum Romanorum Reliquiae* (1870, 1906), and ROME, *History* (ancient) *ad fin.*, section "Authorities," and Livy, where the use made of the annalists by the historian is discussed; Pauly-Wissowa, *Realencyclopädie*, art. "Annales"; the histories of Roman Literature by Teuffel-Schwabe and Schanz-Hosius (bibl.) (H. J. R.)

ANNALS, a concise historical record in which events are arranged chronologically, year by year (*Annales*, from *annus*, a year). The chief sources of information about the annals of ancient Rome are two passages in Cicero (*De Oratore*, ii. 12, 52) and in Servius (*ad Aen.*, i. 373) which have been the subject of much discussion. Cicero states that from the earliest period down to the pontificate of Publius Mucius Scaevola (c. 131 B.C.) it was usual for the pontifex maximus to record on a white tablet (*album*), which was exhibited in an open place at his house, so that the people might read it, first, the name of the consuls and other magistrates, and then the noteworthy events that had occurred during the year (*per singulos dies*, as Servius says). These records were called in Cicero's time *Annales Maximi*. The nature of the distinction between annals and history is a subject that has received more attention from critics than its intrinsic importance deserves. The basis of discussion is furnished chiefly by the above-quoted passage from Cicero, and by the common division of the work of Tacitus into *Annales* and *Historiae*. Aulus Gellius, in the *Noctes Atticae* (v. 18), quotes the grammarian Verrius Flaccus to the effect that history, according to its etymology (*ἱστορεῖν*, *inspicere*, to inquire in person), is a record of events that have come under the author's own observation, while annals are a record of the events of earlier times arranged according to years. This view of the distinction seems to be borne out by the division of the work of Tacitus into the *Historiae*, relating the events of his own time, and the *Annales*, containing the history of earlier periods. It is more than questionable, however, whether Tacitus himself divided his work under these titles. The probability is, either that he called the whole *Annales*, or that he used neither designation.

In the middle ages, when the order of the liturgical feasts was partly determined by the date of Easter, the custom was early established in the Western Church of drawing up tables to indicate that date for a certain number of years or even centuries. These Paschal tables were thin books in which each annual date

was separated from the next by a more or less considerable blank space in which the important events of the year were briefly noted. Among the Anglo-Saxons the compiling of these annals was begun at the end of the 7th century. Introduced by missionaries on the continent, they were augmented and continued, especially in the kingdom of Austrasia. In the 9th century, during the great movement termed the Carolingian Renaissance, these annals became the usual form of contemporary history; it suffices to mention the *Annales Einhardi*, the *Annales Laureshamenses* (or "of Lorsch"), and the *Annales S. Bertini*, officially compiled in order to preserve the memory of the more interesting acts of Charlemagne, his ancestors and his successors. Arrived at this stage of development, the annals now began to lose their primitive character, and henceforward became more and more indistinguishable from the chronicles.

In modern literature the title annals has been given to a large number of standard works which adhere more or less strictly to the order of years. The best known are the *Annales Ecclesiastici*, written by Cardinal Baronius as a rejoinder to and refutation of the *Historia ecclesiastica* or "Centuries" of the Protestant theologians of Magdeburg (Rome, 1788-93; Baronius's work stops at the year 1197). From the 19th century on the annalistic form has been again employed, either to preserve year by year the memory of passing events (*Annual Register*, *Annuaire de la Revue des deux mondes*, *The Year's Work in Classical Studies*, etc.) or in writing the history of obscure mediaeval periods (*Jahrbücher der deutschen Geschichte*, Richter's *Reichsannalen*, etc.).

ANNAM, a country of south-east Asia, the eastern coastal belt of the peninsula of Indo-China (see *INDO-CHINA, FRENCH*), forming a French protectorate with frontiers fixed by treaty (June 6, 1884). It is bounded on the north by Tongking, east and south-east by the China sea, south-west by Cochinchina, and west by Cambodia and Laos. It is 750-800 m. long and has an area of nearly 59,000 sq. m. Pop. (1924) 5,171,986, with 2,466 Europeans, apart from the military. The north of Annam, with plains really belonging to the delta of the Red river, is but a prolongation of south Tongking; yet Annam has marked characteristics of its own in situation, climate and people, quite 90% of whom are indigenous.

AN ANNAMITE COMEDIAN OF TONGKING, INDO-CHINA, ATTIRED IN STAGE COSTUME

The country is traversed longitudinally by the Annamese cordillera which extends south from the high mass of Laos and bends eastward, just as the cordillera of Burma bends westward, under the influence of the Cambodian block between them. A granitic axis is flanked by ancient rocks; which again have Devonian or Carboniferous limestone on their flanks, and there are narrow strips of newer rock along the east coast, while the granitic rocks form most of the south coast and some vulcanicity is indicated. The dissection of the cordillera by rivers has produced the general form of a high axis with high coastward projecting buttresses that separate successive valleys and actually reach the coast here and there. Broadly, the lower ends of the rivers are often consequent, *i.e.*, at right angles to the high axis, but they have worked back into the cordillera and have subsequent, or longitudinal, sections parallel to the axis. As a result of dissection there are fragments of chains in the north and larger plateaux in the south, and some high peaks (Pu Hak, 6,560 ft., Pu Atwat, 8,200 ft., Mother and Child, 6,888 ft.) delimited by deep valleys. The general slope to the east is far sharper than that to the west, and the rivers are short, with courses broken by many rapids. The different parts of the coastal zone are linked by cols such as the Assam Gate (3,900 ft.) in the north, the Col des Nuages (1,540 ft.) in the centre and the Deo Ca (1,310 ft.) in the south. Apart from the fine Tourane bay the coast has little shelter; it is low and flat to Cape Mui-Dong, which stands out; beyond this it remains flat and alluvial southward to Cape Chu May. South again it is more

irregular, and very irregular in the far south, but the bays there are too open to offer good anchorage.

The climate is monsoonal, but the period of the south-west monsoon (mid-April to the end of August), blowing from the land to the sea, is the dry season, with temperatures averaging 82° to 86°, whereas the period of the north-east monsoon (September to April), blowing off the China sea, is wet in autumn, with temperatures averaging about 73°. Typhoons are very frequent, coming almost due west from the sea, and usually following a more southerly course when the sun is far south. The rainfall is about 70 in. per annum.

The cultivation of rice, chiefly in the small deltas along the coast, in some places gives two crops per annum, and constitutes the country's chief harvest. Other vegetable products include maize, tea, tobacco, cotton, precious woods, spices, dyes, drugs and sugar cane. Rubber (*Hevea*) cultivation occupies about 10 sq.m. in the south. As the mulberry is indigenous, silkworm rearing is very old established. Primitive methods of exploitation are being improved; there are about 115 sq.m. of mulberry trees with a production of 920,000 kg. of cocoons. Annam exported 2,577,937 francs worth of raw silk and 1,872,700 francs worth of silk tissues in 1924. In 1920 there were 461,333 head of cattle in Annam.

There is a coalfield at Nong Son near Tourane. Gold, silver, copper, zinc, lead, iron and other metals are frequently met with in the mountains, and there is an important haematite seam at Thanhhoa. There are also numerous salt works. Fisheries are an important native industry, and dried fish and rice are the mainstays of the native diet. Trade is mostly by sea and uses chiefly the port of Tourane (pop. 25,000). The total tonnage of the port is said to be 93,392 including the boats of the French companies: Chargeurs Réunis and Messageries Maritimes. The imports (49,298,171 francs in 1925) include cotton yarn, cottons, tea, petroleum, paper goods and tobacco. Exports (40,620,041 francs in 1925) are sugar, rice, cotton and silk tissues, cinnamon, tea and paper. The ports of Tourane, Kwi-Nhon and Xuan (Chuan) Day bay are open to European commerce; and the customs revenue is ceded to France.

Annam is ruled in theory by its emperor, assisted by the "comat" or secret council, composed of the ministers of the interior, finance, war, ritual, justice and public works nominated by himself. The French resident superior, at Hué (pop. 60,611), is the virtual ruler and advises the emperor with the help of a council (*conseil de protectorat*). Local administration is in the hands of mandarins chosen by competitive examination. In the province of Tourane a French tribunal alone exercises jurisdiction, but it administers native law where natives are concerned. Outside this province native tribunals are maintained. The Annamese village is self-governing. It has its council of notables, forming a sort of oligarchy which, through the medium of a mayor and two subordinates, directs the interior affairs of the community—policing, recruiting, the assignment and collection of taxes, etc.—and has judicial power in less important suits and crimes. More serious cases come within the purview of the *an-sat*, a judicial auxiliary of the governor. An assembly of notables from villages grouped together in a canton chooses a cantonal representative, who is the mouthpiece of the people and the intermediary between the Government and its subjects. The direct taxes, which go to the local budget of Annam, consist primarily of a poll-tax levied on all males over 18 and below 60 years of age, and of a land-tax levied according to the quality and the produce of the holding. Native collaboration in administration is secured to a considerable extent and the French are working for the increase of that collaboration in economic, political and administrative matters. A chamber of representatives of the people was established in 1926. Education is both French and Franco-Annamese and is considerably developed.

The coastal mandarin road, 1,200 km. long, is the chief means of communication, linking all the chief towns. Vinh in the north is linked by rail with Hanoi, the capital of Tongking, and is the starting place of roads into Laos. Phan-Tiet, Phan-Rang, with irrigated areas near by, and Nha-Trang are linked by rail with Saigon, the capital of Cambodia. Binh-Dinh, the largest town, has

70,000 people, and is near the open port of Kwi-Nhon. Tourane has a railway to Hué and beyond, towards Dong-Hoi. Fai-Fo is a little south of Tourane.

History.—The ancient tribe of the Giao-Chi, on the confines of South China and in what is now Tongking and northern Annam, are regarded by the Annamese as their ancestors, and tradition ascribes to their first rulers descent from the Chinese imperial family. These sovereigns were succeeded by another dynasty, during whose rule, at the end of the 3rd century B.C., the Chinese invaded the country, and eventually established there a supremacy destined to last, with little interruption, till the 10th century A.D. In 968 Dinh-Bo-Lanh succeeded in ousting the Chinese and founded an independent dynasty of Dinh. Till this period the greater part of Annam had been occupied by the Chams, a nation of Hindu civilization, which has left many monuments to testify to its greatness, but the encroachment of the Annamese during the next six centuries at last left to it only a small territory in the south of the country. About 1407 Annam again fell under the Chinese yoke. In 1428 an Annamese general Lê-Lôi succeeded in freeing the country once more, and founded a dynasty which lasted till the end of the 18th century. During the greater part of this period, however, the titular sovereigns were mere puppets, the real power being in the hands of the family of Trinh in Tongking and that of Nguyen in southern Annam, which in 1568 became a separate principality under the name of Cochinchina. Towards the end of the 18th century a rebellion overthrew the Nguyen, but one of its members, Gia-long, by the aid of a French force, in 1801 acquired sway over the whole of Annam, Tongking and Cochinchina. This force was procured for him by Pigneau de Béhaine, bishop of Adran, who saw in the political condition of Annam a means of establishing French influence in Indo-China. Before this, in 1787, Gia-long had concluded a treaty with Louis XVI., whereby in return for a promise of aid he ceded Tourane and Pulo-Condore to the French. That treaty marks the beginning of French influence in Indo-China (q.v.).

ANNAN, royal and municipal burgh, Dumfriesshire, Scotland, on the Annan, nearly 2 m. from its mouth and 15 m. from Dumfries by the L.M.S.R. Pop. (1931) 3,959. There is a branch line from Kirtlebridge and a railway viaduct one mile long crosses the Solway Firth to Port Carlisle (Cumberland). The river Annan is crossed by a stone bridge (1824) and a railway bridge. The Harbour Trust, constituted in 1897, improved the shipping accommodation, giving 15 ft. depth at high-water spring tides. The principal industries include bacon-curing, distilling, sandstone quarrying, corn-milling and nursery gardening. Large marine engineering works are in the vicinity. Roman remains exist in the neighbourhood. Edward Irving was a native of the town.

ANNA PERENNA, an old Roman deity of the circle or "ring" of the year, as the name (*per annum*) clearly indicates. Her festival, characterized by revelry and licentiousness, fell on the full moon of the first month (March 15), and was held at the grove of the goddess at the first milestone on the Via Flaminia. Sacrifice was offered to her "that the circle of the year might be happily completed." This is all we know for certain about the goddess and her cult; but the name naturally suggested myth-making, and Anna became a figure in stories in Ovid (*Fasts*, iii, 523 *et seq.*) and in Silius Italicus (viii, 50 *et seq.*). The coarse myth told by Ovid, in which Anna plays a trick on Mars when in love with Minerva, is probably an old Italian folk-tale.

ANNAPOLIS, a city and seaport of Maryland, U.S.A., the capital of the State, the county seat of Anne Arundel county, a port of entry of the Maryland customs district, and the seat of the United States Naval Academy; on the Severn river about 2 m. from its entrance into Chesapeake bay, 26 m. south by east from Baltimore and about the same distance east by north from Washington. The population was 11,214 in 1920, of whom 2,954 were negroes; and was 12,531 in 1930.

Annapolis is one of the most picturesque and historically interesting cities of America. The grounds and buildings of the United States Naval Academy occupy a beautiful site of 200 ac. on the bank of the Severn. On an elevation near the centre of the city stands the State House (1772) with its lofty white dome and pillared portico. Nearby are the State Treasury, erected late in the 17th century for the house of delegates; and St. Anne's Protestant Episcopal church, which was a State church in the later colonial days. A number of residences dating from the 18th century still stand, and colonial associations are further preserved by the names of some of the principal streets, such as King George's, Prince George's, Hanover and Duke of Gloucester.

St. John's college (chartered 1784 as a continuation of King William's school, which had been founded by an act of the legislature in 1696) occupies a campus of 26 ac. adjoining the grounds of the Naval Academy. One of the trees on the campus is believed to be over 600 years old. The main building, McDowell Hall, was built in the 18th century to be the governor's mansion, and was the scene of many historic events. In 1926 the college acquired the Matthias Hammond House (or Harwood House), a beautiful example of the southern Georgian architecture, and has refurnished it as it was in 1774, to be kept as a museum. The college is a non-sectarian institution for men, limited to 400 students. The State offers scholarships to students from each of the counties of Maryland and from the city of Baltimore.

Annapolis was settled in 1649 by Puritan exiles from Virginia. At first it was called Providence; later, Town at Proctor's, Town at the Severn, and Anne Arundel Town; and in 1694 was named Annapolis, in honour of Princess Anne, then heir to the throne of Great Britain. In the same year it was made the seat of the new (royal) government. It was incorporated in 1708. From the middle of the 18th century until the Revolution it was noted for its wealthy and cultivated society, and had a considerable commerce, until Baltimore, in 1780, became a port of entry. Congress was in session in the State House from Nov. 26 1783 to June 3 1784; and it was here that Washington, on Dec. 23 1783, resigned his commission as commander-in-chief of the Continental Army. The "Annapolis Convention" of 1786 was a meeting to which all the States were invited to send delegates, to consider measures for the better regulation of commerce; but as only five States were represented (New York, Pennsylvania, Virginia, New Jersey and Delaware), the delegates merely passed a resolution calling for another convention to meet in Philadelphia the following year, to amend the articles of confederation; and it was this Philadelphia convention that framed the Constitution of the United States.

ANNAPOLIS CONVENTION, a gathering of delegates from several States, of great importance in the movement for a federal convention to revise the articles of confederation. From early colonial days there had been differences of opinion between citizens of Maryland and Virginia relative to the jurisdiction over the waters of Chesapeake Bay and the rivers common to both States. In March, 1785, commissioners representing Maryland and Virginia met at Alexandria for the purpose of arriving at some agreement for the regulation of trade upon these waters. After a session of four days they removed to Mt. Vernon where they finished drawing up a formal compact for joint control. On Dec. 5, 1785, the adhesion of Maryland to the compact was laid before the Virginia legislature, which thereupon promptly announced its approval. In the communication from the legislature of Maryland to the Virginia legislature, a proposal was made to invite commissioners from all the States to meet for the purpose of agreeing upon general commercial regulations. This led to the passage of the well-known resolution of the Virginia legislature (Jan. 21, 1786) which appointed commissioners to meet such commissioners as might be appointed by the other States in the Union to take into consideration the trade of the United States. In answer to this call, five States sent delegates to a convention to be held in Sept. 1786, in the city of Annapolis, Maryland. The States represented at the Annapolis convention were New York, New Jersey, Pennsylvania, Delaware and Virginia. The convention formally opened on Sept. 11, and adjourned on Sept. 14, 1786. New Jersey alone had been liberal in the matter of instruc-

tions. The delegates from the other States were given but little latitude as to their decisions. Because of these restrictions and also because less than half of the States were represented at Annapolis, it was soon apparent that the work of the convention could be merely of a preliminary character. On Sept. 14, the convention adopted an address framed by Alexander Hamilton which prepared the way for the federal convention of 1787. In a concluding paragraph, the delegates, "with the most respectful deference, beg leave to suggest their unanimous conviction, that it may essentially tend to advance the interests of the Union, if the States . . . would use their endeavors to procure the concurrence of the other States, in the appointment of commissioners, to meet at Philadelphia, on the second Monday in May next, to take into consideration the situation of the United States."

Curtis, *History of the Origin, Formation, and Adoption of the Constitution* (1854); and H. J. Ford, *Alexander Hamilton* (1920). (C. C. TA.)

ANNAPOLIS ROYAL, Nova Scotia, capital of Annapolis county and till 1750 of Nova Scotia; on an arm of the Bay of Fundy, at the mouth of the Annapolis river, 95m. W. of Halifax; on the main Canadian Pacific railway. Pop. (1931) 739. It is one of the oldest settlements in North America, founded in 1605 by the French, who called it Port Royal. It was captured by the British in 1710, ceded to them by the treaty of Utrecht in 1713, and renamed in honour of Queen Anne. Its good harbour and beautiful surroundings make it a summer resort. The town is surrounded by apple orchards; fruit is exported.

ANN ARBOR, a city of Michigan, U.S.A., on the Huron river, 38m. W. of Detroit; the county-seat of Washtenaw county. It is served by the Michigan Central and the Ann Arbor railways, and by electric trolley and motor-coach lines. The population was 19,516 in 1920, and was 26,944 in 1930.

Ann Arbor is the trade centre of a rich farming and fruit-growing region. The river provides good water-power, and there are substantial manufacturing industries. In 1927, 47 establishments produced commodities valued at \$7,982,697, including auto-trucks and trailers, furniture, agricultural implements, pianos and organs, pottery and flour. The University of Michigan (*q.v.*) is situated there, and brings to the city a transient population of 12,000 or more in the course of the year. Catering to their needs gives employment, directly or indirectly, to a considerable part of the permanent population. As the university has no dormitories for men, and not enough for women, the single item of providing lodging for students deserves to be mentioned as a major industry.

Ann Arbor was settled, laid out, and chosen as the county-seat in 1824; incorporated as a village in 1833; and chartered as a city in 1851. It was named in honour of Ann Allen and Ann Rumsey, wives of two of the founders.

ANNATES, in the strictest sense of the word, the whole of the first year's profits of a spiritual benefice which, in all countries of the Roman obedience, were formerly paid into the papal treasury (Lat. *annatae*, from *annus*, year; also *primitiae*, first-fruits). This custom was only of gradual growth. It had its origin in the right of the bishop to claim the first year's profits of the living from a newly inducted incumbent, of which the first mention is found under Pope Honorius (d. 1227). The earliest records show the *annata* to have been, sometimes a privilege conceded to the bishop for a term of years, sometimes a right based on immemorial precedent. In course of time the popes, under stress of financial crises, claimed the privilege for themselves, though at first only temporarily. Thus, in 1305, Clement V. claimed the first-fruits of all vacant benefices in England, and in 1319 John XXII. those of all Christendom vacated within the next two years. In those cases the rights of the bishops were frankly usurped by the Holy See, now regarded as the ultimate source of the episcopal jurisdiction; the more usual custom was for the pope to claim the first-fruits only of those benefices of which he had reserved the patronage to himself. It was from these claims that the papal annates, in the strict sense, in course of time developed.

The system of annates was at no time worked with absolute

uniformity and completeness throughout the various parts of the church owing obedience to the Holy See, and it was never willingly submitted to by the clergy. Disagreements and disputes were continual, and the easy expedient of rewarding the officials of the Curia and increasing the papal revenue by "reserving" more and more benefices was met by repeated protests, such as that of the bishops and barons of England (the chief sufferers), headed by Robert Grosseteste of Lincoln, at the Council of Lyons in 1245. The subject, indeed, frequently became one of national interest, on account of the alarming amount of specie which was thus drained away, and hence numerous enactments exist in regard to it by the various national governments. In England the collection and payment of annates to the pope was prohibited in 1531 by statute. At that time the sum amounted to about £3,000 a year. In 1534 the annates were, along with the supremacy over the church in England, bestowed on the Crown; but in Feb. 1704 they were appropriated by Queen Anne to the assistance of the poorer clergy, and thus form what has since been known as "Queen Anne's Bounty" (q.v.).

ANNATTO (*anatto*, *arnotto*), a colouring matter produced from the seeds of *Bixa orellana* (family *Bixaceae*), a small tree which grows in Central and South America. The seeds are surrounded with a thin coating of a waxy pulp, which is separated from them by washing in water, passing the liquid through a sieve and allowing the suspended pulp to deposit. The water is then drained away and the paste dried, till it is a thick, stiff unctuous mass. In this state it has a dark orange-red colour and is known as "roll" or "flag" annatto, according to the form in which it is put up; when further dried it is called "cake" annatto. Annatto is much used by South American Indians for painting their bodies; among civilized communities its principal use is for colouring butter, cheese and varnishes. It yields a fugitive bright orange colour, and is used alone, or with other dyes, in the dyeing of silks and in calico printing. It contains a yellow colouring matter, bixin, $C_{16}H_{26}O_2$.

ANNE (1693–1740), empress of Russia, second daughter of Ivan V., Peter the Great's imbecile brother, and Praskovia Saltukova. Her girlhood was passed at Ismailovo near Moscow, with her mother, an ignorant, bigoted tsaritsa of the old school, who neglected and even hated her daughters. Peter acted as a second father to the Ivanovs, as Praskovia and her family were called. In 1710 he married Anne to Frederick William, duke of Courland, who died of surfeit on his journey home from St. Petersburg (Leningrad). The reluctant young widow was ordered to proceed on her way to Mittau to take over the government of Courland, with the Russian resident, Count Peter Bestuzhev, as her adviser. He was subsequently her lover, till supplanted by Biren (q.v.). Anne's residence at Mittau was embittered by the utter inadequacy of her revenue. On her acceptance of the Russian crown, as the next heir after the death of Peter II. (Jan. 30, 1730), she subscribed to nine articles which would have reduced her from an absolute to a very limited monarch. On Feb. 26 she made her public entry into Moscow under strict surveillance. On March 8 a *coup d'état*, engineered by a party of her personal friends, overthrew the supreme privy council and she was hailed as autocrat. Her government, though in many respects excellent, became at last universally unpopular. This was due in the main to the outrageous insolence of her all-powerful favourite Biren, who hated the Russian nobility and trampled upon them mercilessly. Fortunately foreign affairs and the army were in the able hands of two other foreigners, who thoroughly identified themselves with Russia, Andrei Osterman (q.v.) and Burkhardt Münnich (q.v.). The chief political events of the period were the War of the Polish Succession and the second¹ Crimean War. The former was caused by the reappearance of Stanislaus Leszczyński as a candidate for the Polish throne after the death of Augustus II. (Feb. 1, 1733). The interests of Russia would not permit her to recognize a candidate dependent directly on France and indirectly upon Sweden and Turkey, all three powers being at that time opposed to Russia's "system." She accordingly united with Austria to support

the candidature of the late king's son, Augustus of Saxony. So far as Russia was concerned, the War of the Polish Succession was quickly over. Much more important was the Crimean War of 1736–39, which marks the beginning of that systematic struggle on the part of Russia to recover her natural and legitimate southern boundaries. It lasted four years and a half and cost her a hundred thousand men and millions of roubles, and, though invariably successful, she had to be content with the acquisition of a single city (Azov) with a small district at the mouth of the Don. Yet more had been gained than was immediately apparent. In the first place, it was the only war hitherto waged by Russia against Turkey which had not ended in crushing disaster. Münnich had at least dissipated the illusion of Ottoman invincibility and taught the Russian soldier that 100,000 janissaries and spahis were no match, in a fair field, for half that number of grenadiers and hussars. In the second place the Tatar hordes had been well nigh exterminated. In the third place Russia's signal and unexpected successes in the Steppe had immensely increased her prestige on the Continent. "This court begins to have a great deal to say in the affairs of Europe," remarked the English minister, Sir Claudius Rondeau, a year later.

The last days of Anne were absorbed by the endeavour to strengthen the position of the heir to the throne, the baby tsarevich Ivan, afterwards Ivan VI., the son of the empress's niece, Anna Leopoldovna, against the superior claims of her cousin the tsarevna Elizabeth. The empress herself died three months later (Oct. 28, 1740). Her last act was to appoint Biren regent during the infancy of her great-nephew.

Anne was a grim, sullen woman, frankly sensual, but as well-meaning as ignorance and vindictiveness would allow her to be. But she had much natural good sense, was a true friend and, in her more cheerful moments, an amiable companion. Lady Rondeau's portrait of the empress shows her to the best advantage.

See *Letters from a Lady who resided some years in Russia* (i.e., Lady Rondeau) (1775); Christoph Hermann Manstein, *Mémoires sur la Russie* (Amsterdam, 1771; English edition, London, 1856); Gerhard Anton von Halem, *Lebensschreibung des Feldm. B. C. Grafen von Münnich* (Oldenburg, 1803); Claudius Rondeau, *Diplomatic Despatches from Russia, 1728–1730* (St. Petersburg, 1889–92); R. Nisbet Bain, *The Pupils of Peter the Great* (1897); also the chapter in his vol. vi. of the *Cambridge Modern History* (1925).

ANNE (1665–1714), queen of Great Britain and Ireland, second daughter of James, duke of York, afterwards James II., and of Anne Hyde, daughter of the 1st earl of Clarendon, was born on Feb. 6 1665. As a child she resided in France with her grandmother, Henrietta Maria, and, on her death, with her aunt, the duchess of Orleans, and returned to England in 1670. She was brought up, together with her sister Mary, by the direction of Charles II., as a strict Protestant, and as a child she made the friendship of Sarah Jennings (afterwards duchess of Marlborough). On July 28 1683 she married prince George of Denmark, brother of King Christian V., an unpopular union politically, but one of great domestic happiness, the prince and princess being conformable in temper and both preferring retirement and quiet to life in the great world. Sarah Churchill became Anne's lady of the bedchamber and intimate friend. All deference due to the princess's rank was abandoned and the two ladies called each other Mrs. Morley and Mrs. Freeman.

On Feb. 6, 1685, James became king of England. In 1687 a project of settling the crown on the princess, to the exclusion of Mary, on the condition of Anne's embracing Roman Catholicism failed, and beyond sending her books and papers, James appears to have made no attempt to coerce his daughter into a change of faith, and to have treated her with kindness. In any case the birth of his son, June 10 1688, made the religion of his daughters a matter of less importance. Anne was not present on the occasion, having gone to Bath. "I shall never now be satisfied," Anne wrote to Mary, "whether the child be true or false. It may be it is our brother, but God only knows . . . one cannot help having a thousand fears and melancholy thoughts, but whatever changes may happen you shall ever find me firm to my religion and faithfully yours." In later years, however, she had no doubt that the Old Pretender was her brother.

¹Vasily Golitsuin's expedition under the regency of Sophia was the first Crimean War (1687–89).

During the events immediately preceding the revolution Anne remained in seclusion. Though forbidden by James to pay Mary a projected visit in the spring of 1688, she corresponded with her, and was no doubt aware of William's plans. She refused to show any sympathy with the king after William had landed in November and wrote, with the advice of the Churchills, to the prince, declaring her approval of his action. Churchill abandoned the king on the 24th, Prince George on the 25th, and when James returned to London on the 26th he found that Anne and her lady-in-waiting had escaped from Whitehall. They arrived on Dec. 1 at Nottingham, where the princess first made herself known and appointed a council. She returned to London on Dec. 19, when she was at once visited by William. Subsequently the Declaration of Rights settled the succession of the crown upon her after William and Mary and their children.

Meanwhile Anne had suffered a series of maternal disappointments. Between 1684 and 1688 she had miscarried four times and given birth to two children who died infants. On July 24 1689, however, the birth of a son, William, created duke of Gloucester, who survived his infancy, gave hopes that heirs to the throne under the Bill of Rights might be forthcoming. But Anne's happiness was soon troubled by quarrels with the king and queen.

According to the Duchess of Marlborough the two sisters, who had lived hitherto while apart on extremely affectionate terms, found no enjoyment in each other's society. Mary talked too much for Anne's comfort, and Anne too little for Mary's satisfaction. But money appears to have been the first cause of ill-feeling. The granting away by William of the private estate of James, amounting to £22,000 a year, to which Anne had some claim, was a grievance, and a motion brought forward in the House to increase her civil list pension of £30,000, which she enjoyed in addition to £20,000 under her marriage settlement, greatly displeased William and Mary, who regarded it as a plot to make Anne independent and the chief of a separate interest in the state. The Marlboroughs had been active in the affair and had benefited by it, the countess (as she then was) receiving a pension of £1,000. At the close of 1691 Anne had declared her approval of the naval expedition in favour of her father, and expressed grief at its failure. The same year the breach between the royal sisters was made final by the dismissal of Marlborough, justly suspected of Jacobite intrigues, from all his appointments. Anne took the part of her favourites with great zeal against the court, though in all probability unaware of Marlborough's treason; she refused to part with the duchess, and retired with Lady Marlborough to the duke of Somerset's residence at Sion House. Anne was now in disgrace. In May, Marlborough was arrested on a charge of high treason which subsequently broke down, and Anne persisted in regarding his disgrace as a personal injury to herself. In Aug. 1693, however, the two sisters were temporarily reconciled, and on the occasion of Mary's last illness and death Anne showed an affectionate consideration.

The death of Mary weakened William's position and made it necessary to cultivate good relations with the princess. She was now treated with every honour and civility, and finally established with her own court at St. James's Palace. At the same time William kept her in the background and refrained from appointing her regent during his absence. In March 1695 after the reinstatement of Marlborough at court Anne gave her support to William's government. Meanwhile, since the birth of the duke of Gloucester, the princess had experienced six more miscarriages, and had given birth to two children who only survived a few hours, and the last maternal hope flickered out on the death of the young prince on July 29 1700. In default of her own issue, Anne's personal choice would probably have inclined at this time to her own family at St. Germain's, but she acquiesced in the act of Settlement in 1701 and the substitution of the Hanoverian branch.

On March 8 1702, Anne became, by King William's death, queen of Great Britain, being crowned on April 23. Her reign was destined to be one of the most brilliant in the annals of England.

In her first speech to Parliament, like George III. afterwards,

Anne declared her "heart to be entirely English," words which were resented by some as a reflection on the late king. A ministry, mostly Tory, with Godolphin at its head, was established. She obtained a grant of £700,000 a year, and hastened to bestow a pension of £100,000 on her husband, whom she created generalissimo of her forces and lord high admiral, while Marlborough obtained the Garter, with the captain-generalship and other prizes, including a dukedom, and the duchess was made mistress of the robes with the control of the privy purse.

The queen showed from the first a strong interest in church matters, and declared her intention to keep church appointments in her own hands.

She detested equally Roman Catholics and dissenters, showed a strong leaning towards the high-church party, and gave zealous support to the bill forbidding occasional conformity. In 1704 she announced to the Commons her intention of granting to the church the Crown revenues, amounting to about £16,000 or £17,000 a year, from tithes and first-fruits (paid originally by the clergy to the Pope, but appropriated by the Crown in 1534), for the increase of poor livings; her gift, under the name of "Queen Anne's Bounty," still remaining as a testimony of her piety. This devotion to the church, the strongest of all motives in Anne's conduct, dictated her hesitating attitude towards the two great parties in the state. The Tories had for this reason her personal preference, while the Whigs, who included her powerful favourites the Marlboroughs, identified their interests with the war and its glorious successes, the queen slowly and unwillingly, but inevitably, gravitating towards the latter.

In 1704 Anne acquiesced in the resignation of Lord Nottingham, the leader of the high Tory party. In the same year the great victory of Blenheim further consolidated the power of the Whigs and increased the influence of Marlborough, but she long resisted the influence and claims of the *Junta*, as the Whig leaders, Somers, Halifax, Orford, Wharton and Sunderland, were named. Marlborough's successive victories, and the factious conduct of the Tories, who in Nov. 1705 moved in Parliament that the Electress Sophia should be invited to England, drove Anne farther to the side of the Whigs. But she opposed for some time the inclusion in the government of Sunderland, yielded, after a struggle, and only to the appointment of Whigs to bishoprics. In 1708 she was forced to dismiss Harley, who, with the aid of Mrs. Masham, had been intriguing against the government and projecting the creation of a third party. Abigail Hill, Mrs. Masham, a cousin of the duchess of Marlborough, had been introduced by the latter as a poor relation into Anne's service, while still princess of Denmark. The queen found relief in the quiet and respectful demeanour of her attendant, and gradually came to prefer her society to that of the termagant and tempestuous duchess. In the summer of 1707 the duchess discovered to her indignation that her protégée had already undermined her influence with the queen, and had become the instrument of Harley's intrigue.

Even after his retirement, Harley remained Anne's secret adviser and supporter against the faction and the duchess never regained her former influence. The inclusion in the cabinet of Somers, whom she especially disliked as the hostile critic of Prince George's Admiralty administration, was the subject of another prolonged struggle, ending again in the queen's submission after a futile appeal to Marlborough in Oct. 1708, to which she brought herself only to avoid a motion from the Whigs for the removal of the prince, then actually on his deathbed. He died Oct. 28. But no reconciliation with the duchess took place. The queen showed her antagonism to the Whig administration on the occasion of the prosecution of Sacheverell. She was present at his trial, and gave him, immediately on the expiration of his sentence, the living of St. Andrew's, Holborn. Subsequently the duchess, in a final interview which she had forced upon the queen, found her tears and reproaches unavailing. The fall of the Whigs followed.

The queen rejoiced at being freed from what she called a long captivity, and the new Parliament was returned with a Tory majority. On Jan. 17 1711, in spite of Marlborough's efforts to ward off the blow, the duchess was compelled to give up her key

of office. The Queen was now able once more to indulge in her favourite patronage of the church, and by her influence an act was passed in 1712 for building 50 new churches in London. Later, in 1714, she approved of the Schism Bill. She gave strong support to Harley, now earl of Oxford and lord treasurer, in the intrigues and negotiations for peace. To break down the opposition to the terms of the peace of Utrecht Marlborough was dismissed on the 31st from all his employments, while the House of Lords was "swamped" by Anne's creation of 12 peers, including Mrs. Masham's husband. The Queen's conduct was generally approved, for the nation was now violently adverse to the Whigs and war party; and the peace of Utrecht was finally signed on March 31 1713, and proclaimed on May 5 in London.

As the Queen's reign drew to its close, rumours were rife on the subject of the succession to the throne. Both Oxford and Bolingbroke were in communication with the Pretender's party, and on July 27 Oxford, who had gradually lost influence and quarrelled with Bolingbroke, resigned, leaving the supreme power in the hands of Bolingbroke. Anne herself had a natural feeling for her brother. On March 3 1714 James wrote to Anne, Oxford and Bolingbroke, promising, on the condition of his recognition, to make no further attempts against the Queen's Government; and in April a report was circulated in Holland that Anne had secretly determined to associate James with her in the Government. The wish expressed by the Whigs, that a member of the electoral family should be invited to England, had already aroused the Queen's indignation in 1708; and now, in 1714, a writ of summons for the electoral prince as Duke of Cambridge having been obtained, Anne forbade the Hanoverian envoy, Baron Schütz, her presence, and declared all who supported the project her enemies; while to a memorial on the same subject from the Electress Sophia and her grandson in May, Anne replied in an angry letter.

These demonstrations, however, were the outcome merely of her intense dislike of any "successor," "it being a thing I cannot bear to have any successor here though but for a week"; and it is certain that religion and political wisdom kept Anne firm to the Protestant succession. A proclamation was issued (June 23) for the apprehension of James. On April 27, Anne gave a solemn assurance of her fidelity to the Hanoverian succession to Sir William Dawes, Archbishop of York; in June she sent Lord Clarendon to Hanover to satisfy the elector.

The sudden illness and death of the Queen now frustrated any schemes which Bolingbroke or others might have been contemplating. Anne was seized with fatal illness on retiring from a council meeting at two o'clock in the morning. The final act of her life was to secure the Revolution settlement and the Protestant succession. During a last moment of returning consciousness, she placed the lord treasurer's staff in the hands of the Whig duke of Shrewsbury, and measures were immediately taken for assuring the succession of the elector. Her death took place on Aug. 1. She was buried on the south side of Henry VII.'s chapel in Westminster Abbey, in the same tomb as her husband and children. The elector of Hanover, George Louis, son of the Electress Sophia (daughter of Elizabeth, daughter of James I.), peacefully succeeded to the throne as George I. (q.v.).

According to her physician Arbuthnot, Anne's life was shortened by the "scene of contention among her servants. I believe sleep was never more welcome to a weary traveller than death was to her."

By character and temperament unfitted to stand alone, her life had been unhappy and tragical from its isolation. Separated in early years from her parents and sister, her one great friendship had proved only baneful and ensnaring. Marriage had only brought a mournful series of infant funerals. Constant ill-health and suffering had darkened her career. The claims of family attachment, of religion, of duty, of patriotism and of interest, had dragged her in opposite directions, and her whole life had been a prey to jealousies and factions which closed around her at her accession to the throne, and surged to their height when she lay on her deathbed. The modern theory of the relations between the sovereign and the parties, had not then been invented; and Anne, like her Hanoverian successors, maintained the struggle,

though without success, to rule independently, finding support in Harley. Her motive for getting rid of the Whigs was not any real dislike of their administration, but the wish to escape from the domination of the party¹, and on the advent to power of the Tories she carefully left some Whigs in their employments, with the aim of breaking up the party system and acting upon what was called "a moderate scheme."

Anne was a woman of small ability, of dull mind, and of that kind of obstinacy which accompanies weakness of character. According to the duchess she had "a certain knack of sticking to what had been dictated to her to a degree often very disagreeable, and without the least sign of understanding or judgment."² "I desire you would not have so ill an opinion of me," Anne writes to Oxford, "as to think when I have determined anything in my mind I will alter it."³ Burnet considered that "she laid down the splendour of a court too much," which was "as it were abandoned." She dined alone after her husband's death, but it was reported by no means abstemiously, the royal family being characterized in the lines:—

King William thinks all,
Queen Mary talks all,
Prince George drinks all,
And Princess Anne eats all.⁴

She took no interest in the art, the drama or the literature of her day. But she possessed the homely virtues; she was deeply religious, attached to the Church of England and concerned for the efficiency of the ministry. One of the first acts of her reign was a proclamation against vice, and Lord Chesterfield regretted the strict morality of her court. Instances abound of her kindness and consideration for others. Her moderation towards the Jacobites in Scotland, after the Pretender's expedition in 1708, was much praised by Saint Simon.

According to her small ability she served the State well, and was zealous and conscientious in the fulfilment of public duties. Marlborough testifies to her energy in finding money for the war. She surrendered £10,000 a year for public purposes, and in 1706 she presented £30,000 to the officers and soldiers who had lost their horses.

Anne's husband, Prince George (1653-1708), was the second son of Frederick III., king of Denmark. Before marrying Anne he had been a candidate for the throne of Poland. He was created earl of Kendal and duke of Cumberland in 1689.

ANNE OF BRITTANY (1477-1514), duchess of Brittany and queen consort of France, daughter of Francis II., duke of Brittany, and Marguerite de Foix. She was scarcely 12 years old when she succeeded her father as duchess, Sept. 9 1488. Charles VIII. aimed at establishing his authority over her; Alain d'Albret wished to marry her; Jean de Rohan claimed the duchy; and her guardian, the marshal de Rieux, was soon in open revolt against his sovereign. In 1489 the French Army invaded Brittany.

In order to protect her independence, Anne concluded an alliance with Maximilian of Austria, who married her by proxy (Dec. 1490). But Maximilian was immersed in Austrian affairs and could not defend his bride, and in 1491 the young duchess was besieged at Rennes, and compelled to treat with Charles VIII. The terms of peace included the rupture of her marriage with Maximilian, and marriage with Charles. The two sovereigns made a reciprocal arrangement as to their rights and pretensions to the crown of Brittany, but in the event of Charles predeceasing her, Anne undertook to marry the heir to the throne. Nevertheless, in 1492, after the conspiracy of Jean de Rohan, who had endeavoured to hand over the duchy to the king of England, Charles VIII. confirmed the privileges of Brittany, and in particular guaranteed to the Bretons the right of paying only those taxes to which the Assembly of Estates consented.

After the death of Charles VIII. in 1498, without issue, Anne ruled in Brittany, and in Jan. 1499 she married Louis XII., who had just repudiated Joan of France. The marriage contract was ostensibly directed in favour of the independence of Brittany, for it declared that Brittany should revert to the second son or to the eldest daughter of the two sovereigns, and, failing issue, to the natural heirs of the duchess. Until her death Anne occupied herself personally with the administration of the duchy. In 1504 she made an agreement for the marriage of her daughter, Claude of France, to Charles of Austria (the future Emperor Charles V.). But this unpopular agreement was broken and the queen had to consent to the betrothal of Claude to Francis of Angoulême, who in 1515 became king of France as Francis I. Thus the way was prepared for the definitive reunion of Brittany and France.

(1866 and 1868); P. A. N. B. Daru, *Histoire de Bretagne* (1816); Leroux de Lincy, *Vie de la reine Anne de Bretagne* (1860-61); A. Dupuy, *Histoire de La Réunion de la Bretagne à la France* (1880); A. de la Borderie, *La Bretagne aux derniers siècles du moyen âge* (1893), and *La Bretagne aux temps modernes* (1894). (H. S.)

ANNE OF CLEVES (1515-1557), fourth wife of Henry VIII., king of England, daughter of John, duke of Cleves, and Mary, only daughter of William, duke of Juliers, was born on Sept. 22, 1515. Her father was the leader of the German Protestants, and the princess, after the death of Jane Seymour, was regarded by Cromwell as a suitable wife for Henry VIII. She had been brought up in a narrow retirement, could speak no language but her own, had no looks, no accomplishments and no dowry, her only recommendations being her proficiency in needlework and her meek and gentle temper. The marriage treaty was signed on Sept. 24, 1539. The princess landed at Deal on Dec. 27; Henry met her at Rochester on Jan. 1, 1540. The next day he expressed openly his dissatisfaction at her looks; "she was no better than a Flanders mare." The attempt to prove a pre-contract with the son of the duke of Lorraine broke down. On the wedding morning, however, Jan. 6, 1540, he declared that no earthly thing would have induced him to marry her but the fear of driving the duke of Cleves into the arms of the emperor. Shortly afterwards Henry had reason to regret the policy which had identified him so closely with the German Protestantism and denied reconciliation with the emperor. Henry then declared the marriage had not been and could not be consummated, and did not scruple to cast doubts on his wife's honour. On July 9 the marriage was declared null and void by convocation and, subsequently, by an act of parliament. Anne spent the rest of her life happily in England at Richmond

or Bletchingley, occasionally visiting the court, and being described as joyous as ever and wearing new dresses every day. She died on July 28, 1557, at Chelsea, and was buried in Westminster Abbey.

See A. Strickland, *Lives of the Queens of England*, iii. (1851); *Four Original Documents relating to the Marriage of Henry VIII. to Anne of Cleves*, ed. by E. and G. Goldsmid (1884); M. Hume, *The Wives of Henry VIII.* (1905); A. F. Pollard, *Henry VIII.* (1905); for the pseudo Anne of Cleves see *Allgemeine deutsche Biographie*, i. 467. A miniature by Holbein is in South Kensington Museum.

ANNE OF DENMARK (1574-1619), queen of James I. of England and VI. of Scotland, daughter of King Frederick II. of Denmark and Norway and of Sophia, daughter of Ulric III., duke of Mecklenburg, was born on Dec. 12 1574. On Aug. 20 1589, in spite of Queen Elizabeth's opposition, she was married by proxy to King James, without dower, the alliance, however, settling definitely the Scottish claims to the Orkney and Shetland islands. The birth of an heir to the throne (Prince Henry) in 1594 strengthened her position and influence; but the young prince was immediately withdrawn from her care and entrusted to the keeping of the Earl and Countess of Mar at Stirling Castle; in 1595 James gave a written command, forbidding them in case of his death to give up the prince to the queen till he reached the age of 18 years.

On the death of Queen Elizabeth, on March 24 1603, Anne took advantage of James's absence to demand possession of the prince, and, at the "flat refusal" of the Countess of Mar, fell into a passion, the violence of which occasioned a miscarriage and endangered her life. In June she followed the King to England with the prince and the coffin containing the body of her dead infant, and reached Windsor on July 2.

On July 24 Anne was crowned with the King, when her refusal to take the sacrament according to the Anglican use created some sensation. Notwithstanding religious differences she lived in great harmony and affection with the King, latterly, however, residing mostly apart. She helped to raise Buckingham to power in the place of Somerset, maintained friendly relations with him, and approved of his guidance and control of the King. In spite of her birth and family she was at first favourably inclined to Spain, disapproved of her daughter Elizabeth's marriage with the elector palatine, and supported the Spanish marriages for her sons, but subsequently veered around towards France.

She used all her influence in favour of the unfortunate Raleigh, answering his petition to her for protection with a personal letter of appeal to Buckingham to save his life. Her interest in State matters was only occasional, and secondary to the preoccupations of court festivities, dresses, jewels, which she much enjoyed; the court being, says Wilson—whose severity cannot entirely suppress his admiration—"a continued maskarado, where she and her ladies, like so many nymphs or Nereides, appeared . . . to the ravishment of the beholders," and "made the night more glorious than the day." Her extravagant expenditure, returned by Chamberlain at her death at more than £84,000, was unfavourably contrasted with the economy of Queen Elizabeth; her debts in 1616 were reckoned at nearly £10,000, while her jewellery and her plate were valued at her death at nearly £500,000. Anne died after a long illness on March 2 1619, and was buried in Westminster Abbey. She was generally regretted. She was intelligent and tactful, a faithful wife, a devoted mother, and a staunch friend. Besides several children who died in infancy she had Henry, Prince of Wales, who died in 1612, Charles, afterwards King Charles I., and Elizabeth, electress palatine and queen of Bohemia.

ANNE OF FRANCE (1460-1522), dame de Beaujeu, was the eldest daughter of Louis XI. and Charlotte of Savoy. Louis XI. betrothed her at first to Nicholas of Anjou, and afterwards offered her hand successively to Charles the Bold, to the duke of

Brittany, and even to his own brother, Charles of France. Finally she married Pierre de Beaujeu, a younger brother of the duke of Bourbon. Before his death Louis XI. entrusted to Pierre de Beaujeu and Anne the entire charge of his son, Charles VIII., a lad of 13; and from 1483 to 1492 the Beaujeus exercised a virtual regency. Anne was a true daughter of Louis XI. Energetic, obstinate, cunning and unscrupulous, she inherited, too, her father's avarice and rapacity.

Although they made some concessions, the Beaujeus succeeded in maintaining the results of the previous reign, and in triumphing over the feudal intrigues and coalitions, as was seen from the meeting of the Estates General in 1484, and the results of the "Mad War" (1485) and the war with Brittany (1488); and in spite of the efforts of Maximilian of Austria and Henry VII. of England they concluded the marriage of Charles VIII. and Anne, duchess of Brittany (1491). But a short time afterwards the king disengaged himself completely from their tutelage, to the great detriment of the kingdom. In 1488 Pierre de Beaujeu had succeeded to the Bourbonnais, the last great fief of France. He died in 1503, but Anne survived him 20 years. From her establishments at Moulins and Chantelle in the Bourbonnais she defended the Bourbon cause against the royal family.

Anne's only daughter, Suzanne, had married in 1505 her cousin, Charles of Bourbon, count of Montpensier, the future constable; and the question of the succession of Suzanne, who died in 1521, was the determining factor of the treason of the Constable de Bourbon (1523). Anne had died on Nov. 14 1522.

See P. Pelicier, *Essai sur le gouvernement de la Dame de Beaujeu* (Chartres, 1882).

ANNEALING, a process of heating and cooling applied to glass and various metals and alloys, with the object of relieving stresses, or of altering the properties of the material. The result is softening, due to rearrangement. In its modern form the process is effected in closed furnaces. Another class of annealing is chemical in nature, being practised in the production of malleable iron castings. The chemical action occurs through the agency of substances, containing oxygen, packed with the castings in boxes and left for many days in the furnace. These substances extract the carbon from the castings.

Annealing Tool Steels.—Annealing becomes necessary for a variety of reasons in numerous manufactures. An early primary reason was and is to soften steel used to make tools, so that it can be cut, filed, turned, and so on, tools having no effect on hardened steel, though it may be ground with an abrasive wheel. Hence any hard bar or tool, if it cannot be worked up or sharpened by grinding, must be softened or annealed first. Bars and tools likewise require annealing after certain processes in manufacture, as casting, rolling, forging, and machining, in order to relieve the internal stresses caused thereby, otherwise the tools made therefrom would crack in hardening or in use. Annealing temperatures vary from 700° to 800° C. for carbon tool-steels, and from about 750° to 900° C. for high-speed tool-steels.

Annealing is also used in processes of manufacturing glass and many other materials. Not only relieving the strain, the annealing causes a rearrangement of the micro-constituents, improving homogeneity. An important essential is to avoid such application of heat as will cause scaling of the metal or alloy. Entire protection in a box or a muffle is sometimes given, or if direct flame impinges on the article, the quality of flame is regulated suitably to avoid fierce action. What is termed bright annealing is the most remarkable attainment in this direction, whereby stampings and other objects of steel, copper, brass, German-silver, etc., may be annealed once or several times with entire freedom from oxidation, scaling or discolouration. Polished surfaces left from rolling, drawing or other machines thus remain clean and bright, and cleansing treatments are rendered unnecessary.

An important application of annealing is its use on chains for pulley-blocks, cranes and other hoisting tackle, as well as some sorts of couplings subject to incessant duty. These become crystalline and fatigued if kept in service too long, and they are liable to fracture; but if the chains are annealed at intervals, this danger disappears.

Annealing Furnaces.—Furnaces for annealing are heated by coal, coke, town or producer gas or oil. The two first-mentioned fuels are not employed much for small furnaces. The smallest furnaces are but a few inches inside capacity, the largest will take steel plates, as much as 60ft. in length. Pieces of work go direct on the floor of the furnace, or in closed boxes, or the furnace is of muffle type, the flame being kept outside the heating chamber. Insertion and removal of the smaller specimens is performed by hand methods, but large units or batches of stampings, coils of wire, etc. require the help of a trolley or a crane. Special charging machines are also used that push the articles in by electric power, or hand gearing. In the case of the 60ft. plates referred to insertion or removal may be effected in 1½ minutes, leaving no risk of overheating of the end of the plate which enters the furnace first and leaves it last.

Large quantities of articles of small or moderate size are dealt with continuously by some form of conveyor system. For cartridges a rotary machine is utilised, having gas-burners which impinge on the shells whilst these are carried around automatically, and afterwards discharged down a chute. Closed furnaces have a spiral retort that passes the components through in a certain time, or a conveyor chain takes these through the length of the furnace. Bright annealing is largely done with conveyors.

Variations in Furnace Types.—In some furnaces the flames are kept away from the work, being carried round hollow walls. If the reverberatory construction is adopted, the heat descends directly on to the objects. Gas furnaces operate by natural draught or by blast, the latter giving a quicker heating up, and greater

FIG. 1.—SECTION OF A BRAYSHAW, OVEN TYPE, ANNEALING FURNACE SHOWING ONE OF THE BURNERS AND ONE AIR-PIPE. The body is of fire-brick. Waste products, passing in the direction shown by the arrows, heat the air-pipes and thus assist combustion.

temperature. Oil may be used in such furnaces, with a difference in the form of burner. Fig. 1 may be studied to understand the arrangement of an oven type annealing furnace. The body is composed of fire-brick bound together with plates and bars, and the design is of the recuperative style; the waste products pass in the direction of the arrows, and so heat the air-pipes, thus assisting combustion. In another design the incoming air is pre-heated by first passing under the furnace floor. In either class there is a marked saving in fuel. The twin-chamber furnace affords another example of economy, this having an upper chamber heated by waste products from the main one below; the work consequently may be pre-heated before being put into the main chamber. A section of a Manchester furnace (fig. 2, p. 988) shows the grate and flue arrangements; heating can be done by coal or coke or

both mixed. Special recuperative flues are built in alongside the fire-box for pre-heating the air, these not in the section. Temperatures up to 1100°C are easily maintained. It may be mentioned that uniformity of heating is imperative for good work, while maintenance of the correct temperature (within a few degrees) should be guaranteed. See also MATERIALS, STRENGTH OF and FORGING. (F. H.)

FIG. 2.—A MANCHESTER FURNACE WHICH CAN MAINTAIN, WITH CLOSE UNIFORMITY, A TEMPERATURE OF 1100°C

ANNECY, a chief town of the department of Haute Savoie, France. Pop. (1926) 15,389. It is situated at a height of 1,470ft., amid fine scenery under the Crêt du Maure at the north end of the Lake of Annecy, 25m. by rail N.E. of Aix-les-Bains. Annecy was in the 10th century the capital of the counts of the Genevois, from whom it passed in 1401 to the counts of Savoy, becoming French in 1860 on the annexation of Savoy. The town, with its arcaded streets, is intersected by canals, and contains a 16th century cathedral church, an 18th century bishop's palace, and 14th-16th century castle (formerly the residence of the counts of the Genevois), and the reconstructed convent of the Visitation (10th century), which contains the body of St. François de Sales, born at Sales, close by, who held the see from 1602-22. The bishop's see of Geneva was transferred hither in 1535, after the reformation, but suppressed in 1801, though revived in 1822. Linen and cotton goods, chocolate, leather, paper and small mechanical fittings are made; and a bell foundry at Annecy-le-Vieux is celebrated. This last-named place existed in Roman times.

The lake of Annecy, about 9m. by 2m., is 1,465ft. above sea level. It discharges, by means of the Thioux canal, into the Fier, which flows through remarkable gorges cut in the soft local sandstone, west of the town, to join the Rhône.

ANNELIDA. The Phylum Annelida includes the segmented worms. They differ from the Arthropoda in the possession of a perivisceral cavity which is a part of the coelom and from the Mollusca in the fact that the body is segmented. This segmentation has its origin in the mesoblastic somites of the embryo, just as the perivisceral coelom is derived from the paired cavities of the embryonic mesoblast. Except for the majority of the Hirudinea, a few Archiannelida and Oligochaeta, the whole phylum possesses segmentally arranged chitinous chaetae or bristles, from which the name Chaetopoda or bristle-footed worms is derived.

They are with few exceptions elongated, bilaterally symmetrical animals with a body composed of a series of similar segments, not modified to form different parts of the body as in the Arthropods, from which the Annelids differ also in the unjointed character of their locomotory appendages. A head-region is however normally distinguished, and the thorax is often marked off from the abdomen.

Chaetae.—The chaetae (*setae*) or bristles which are, except for the Brachiopoda (*q.v.*), specific to this group, are delicate chitinous structures showing immense variability in size and shape.

Coelom.—In its simplest form the coelom consists of a series of chambers which correspond to the segments of the body and

are separated from one another by intersegmental septa extending from the body-wall to the gut. This condition may be modified either in the direction of the suppression of the septa as in some Polychaeta, or of the further sub-division of the coelom as in the more modified Oligochaeta. The latter tendency is most marked in the Hirudinea in which the coelom is partially suppressed. The coelom communicates with the exterior by a number of ways; by the dorsal pores of the Oligochaeta, by the nephridia and by the coelomoducts.

Nephridia and Coelomoducts.—A nephridium is typically a ciliated tube from the coelom to the exterior, consisting of a chain of cells in which a continuous lumen is pierced, and ending internally in a ciliated funnel. Its function is to remove excretory products from the coelom. The coelomoducts, which include the majority of the genital ducts of the Annelids, are somewhat similar structures but the lumen of the tube is intercellular. Moreover according to E. S. Goodrich the true nephridium is an ingrowth from the ectoderm, whereas the coelomoduct is a coelomic outgrowth. These distinctions are only valid within limits.

The Vascular System.—This system in the Annelids is typically closed, that is to say there is in addition to the coelom a further system of closed spaces, the haemal system, between the gut and the body-wall. A dorsal and a ventral vessel joined by a number of connectives are usually present.

Nervous System.—The nervous system consists of a ventral ganglionated cord joining the cerebral ganglia or brain by a circumoesophageal commissure. The cord normally lies in the coelom but in a few forms it is embedded in the epidermis.

Gonads.—The gonads are segmental proliferations of the coelomic epithelium.

Classification.—The Phylum Annelida is usually divided into the following classes:—The Archiannelida, the Polychaeta or marine bristle-worms, the Oligochaeta or aquatic and terrestrial bristle-worms, the Myzostomaria, and the Hirudinea or leeches.

If we except the Echiuroidea, the Chaetopoda are co-extensive with the Annelids.

ARCHIANNELIDA

The Archiannelida or Haplo-drili are a small group of simply organized marine, aquatic and terrestrial worms, which have been affiliated by various authors with the Rotifera, the Turbellaria and the Annelida. The most recent opinion is that they are modified and often degenerate Annelids allied to the Polychaeta. The view taken of the group as a whole must depend upon the number of forms the student elects to include in it. For example E. Reisinger in his survey of the group published in 1925 claims as Archiannelids the genera *Aeolosoma* and *Pleurophleps* usually attributed to the Oligochaeta; similarly he includes in that group as the family *Ctenodrilidae* the genera *Zeppelina*, *Ctenodrilus* and *Raphidrilus*, which P. Fauvel treats as a sub-division of the Polychaete family *Cirratulidae*, and again Fauvel regards as a true Polychaete *Histiobdella*, which Reisinger put among the Archiannelida.

The older view that the Archiannelida are primitive forms is no longer generally held: many of the features regarded by the older authors as primitive are due to the persistence into adult life of larval characters or to degeneration, the outcome of a parasitic habit of life. Moreover these putatively primitive features are in most cases equally found in well characterized Polychaetes. Thus the fusion of the nervous system with the epidermis, the presence of bands of cilia, a very simple vascular system, even

AFTER KORSCHULT FROM FAUVEL, "POLYCHETES SEDENTAIRES," BY COURTESY OF FED. FRANC. DES SOC. DE SCIEN. NAT.
FIG. 1.—DINOPHILUS GYROCILATUS, ENLARGED

the absence of chaetae have their counterpart in the Polychaeta. A definition of the group as a whole is rendered impracticable by its heterogeneous nature, and the families are best treated separately.

Fauvel recognizes four families: I. The *Dinophilidae*; II. The *Parergodrilidae*; III. The *Polygordiidae*; IV. The *Nerillidae*.

The *Dinophilidae* are small marine Archiannelida without either appendages or chaetae, with bands of cilia and with a short caudal region provided with adhesive glands: there is an unarmed exsertile proboscis; the sexes are separate and often a marked sexual dimorphism exists. They have been affiliated with both the Rotifera and the Turbellaria: E. Perrier who created for them the class Trichotoma, regarded them as intermediate between the Turbellaria and the Nemertea. They are probably Annelids which have retained their larval characters. The reproductive processes of *Dinophilus gyrocolatus* are of great interest and have been much studied.

The *Parergodrilidae* are terrestrial Archiannelids living in humus and in damp leaves: only one species, *Parergodrilus heideri*, is known. They are distinctly segmented, without appendages or bands of cilia, with segmental dorsal glands, with two rows of chaetae of an Oligochaetous type, with a cerebral ganglion, an unsegmented unpaired nerve-cord in direct contact with the epidermis, a well developed digestive system and several pairs of nephridia. They are hermaphrodite; and they use their exsertile proboscis and chaetae for climbing.

The *Polygordiidae* are relatively large marine, rarely freshwater, vermiform Archiannelids, more or less cylindrical in shape, usually with a ventral ciliated groove and segmental bands of cilia; with two tentacles and with a pygidium provided with adhesive glands. *Polygordius*, distinguished from *Protodrilus* by the absence of the ventral ciliated groove and of distinct lobes

FIG. 3.—DORSAL VIEW, ENLARGED,
OF TROGLODRILUS BERANECKI

a freshwater worm found in caves. *Nerilla* and *Nerillidium* are both marine forms. *Nerilla* has many points of resemblance to *Protodrilus* and *Saccocirrus*. *Nerillidium* is an intermediate form between *Troglodrilus* and *Nerilla*.

BIBLIOGRAPHY.—The more recent comprehensive works on the group are: K. Heider, "Über Archianneliden" *Sitzber. Ak. Wiss. Berlin*, VI.

(1922); E. Reisinger, "Ein landbewohnender Archiannelide. (Zugleich ein Beitrag zur Systematik der Archianneliden)" *Zs. Morphol. Oekol. Tiere*, Bd. III. (1925); P. Fauvel, "Archiannelides" in "Polychètes sédentaires," etc., *Faune de France* XVI. (1927), containing a large bibl. incorporated with the general Polychaete bibl.; the extensive specific synonymies make it easy to pick out the works dealing with the Archiannelida. (C. C. A. M.)

POLYCHAETA

The Polychaeta include the marine bristle-worms. A very few species have adopted a freshwater habitat. They differ from the other great subdivision of the Annelida, the Oligochaeta, in the following ways. In the Oligochaeta there are no appendages, and the bristles are embedded directly in the body-wall; there is a clitellum and hermaphroditism is the normal condition. In the Polychaeta there are almost always appendages of various kinds, the numerous bristles are borne by special organs, the parapodia; there is no clitellum and the sexes are separate.

External Anatomy.—The general form varies greatly according to the mode of life of the animal, which may be active or sedentary. The body is usually divided into the cephalic lobe or prostomium, the buccal segment or peristomium, together usually called the head (fig. 4) (in forms where cephalization is advanced this term includes additional elements), the metastomium or body proper which is often marked off into thorax and abdomen, and the pygidium or terminal segment. The prostomium may assume a variety of forms, square, conical, complex or annulated. It is

FIG. 4.—A. SIDE VIEW OF THE HEAD REGION OF NEREIS CULTRIFERA.
B. DORSAL VIEW

usually provided with eyes, which range from simple pigment spots to complex organs with a crystalline lens. The head often carries a number of appendages, the tentacles, palps, tentacular cirri, which are innervated from different sources. Morphologically the appendages in the Polychaeta are divisible into two groups, those which are purely epidermal and solid and those which are hollow and contain all the elements of the body-wall. In the majority of the appendages these two groups are com-

bined, the hollow basal portion being designated by the termination—phore, and the solid terminal portion by the termination—style. Thus there are palpostyle and palpophore, cirrostyle and cirrophore.

Parapodia.—The parapodia or feet in which the bristles are implanted are hollow outgrowths of the body-wall. They are typically composed of two branches, the dorsal or notopodium

FROM MCINTOSH, "BRITISH ANNELIDS," BY COURTESY OF THE RAY SOCIETY
FIG. 5.—FOOT OF NEREIS CULTRIFERA

and the ventral or neuropodium. The foot may be a very complex structure as in the *Nereidae*, with various membranous expansions and lamellae. (Fig. 5.) Each branch of the parapodium is supported internally by stout chitinous rods, the acicula, and there are usually a dorsal and a ventral cirrus: on the upper surface of the foot in some groups simple or ramified branchiae are present. In the sedentary orders the ventral lobe is reduced to a transverse ridge or torus uncinigerus, in which are embedded numerous small hooks.

Bristles.—The chaetae or bristles display an immense variety of form. They are divisible into bristles proper and hooks. The bristles proper may be simple or compound. Simple bristles may be smooth and capillary, or toothed in an almost indefinite number of ways. They may be shaped like a paintbrush as in *Panthalis*; pectinate as in the *Eunicidae*; winged as in the *Terebellidae*; transversely excavated as in *Nephtys*; or paddle-shaped as in the heteronereids. The compound bristles consist of a basal article with which is articulated a terminal piece. The uncini or

hooks of the Sedentaria are small chitinous plates the external edge of which is broken up into a series of minute teeth; or there may be one main tooth with rows of smaller teeth above it. (Fig. 6, a to h.)

Morphology.—The outer layer of the body-wall consists of an epidermis, which is sometimes ciliated, and a cuticle. The epidermis is composed of supporting cells and gland cells. The bases of the supporting cells may form a basal layer, and in certain regions the epidermis may be greatly thickened as in the gland shields of the *Terebellids* which secrete the mucus employed in the building of their tubes. Beneath the epidermis there are three muscle-layers, a circular, a longitudinal, and an oblique, of which the longitudinal is the most important. The muscles are unstriped. The body-wall is lined by a coelomic epithelium and besides the sexual elements the coelom contains amoebocytes, leucocytes, phagocytes, etc. In the Sedentaria there is a tendency for the segmental septa to break down and for the coelom especially in the thoracic region to become a continuous cavity extending over many segments, as in *Arenicola*.

Alimentary Canal.—The alimentary canal is usually a straight tube from mouth to anus; but in some of the Sedentaria, notably in the *Amphictenidae*, it is much coiled. In a number of families the digestive tube begins with an exsertile proboscis provided sometimes with complex chitinous jaws and sometimes with soft papillae. It can often be divided up macroscopically into a number of regions, a pharynx, gizzard, stomach, intestine, etc. *Nereis* for example has a stout armed proboscis, an oesophagus, a thick walled gizzard with caeca and a moniliform intestine. *Syllis* has a buccal bulb followed by a pharynx armed with a tooth; then comes a curious barrel-shaped proventriculus, a ventriculus with a pair of T-shaped caeca and a moniliform intestine. In the *Capitellidae* there occurs an accessory intestine or siphon similar to that in the *Echiuridae*.

Vascular System.—This system is very variable. It is normally closed, and in the widest terms consists of a dorsal and a ventral vessel with a number of transverse connectives. In some groups it is rudimentary or even absent as in the *Glyceridae* and the *Capitellidae*. In certain families of the Sedentaria there is a special contractile body known as the heart which may enclose a cardiac body. The blood is usually bright red: it may be colourless as in the *Syllids*, or green as in the *Serpulidae*. The latter colour is due to the presence of chlorocruorin in solution in the

plasma. In a few species in addition to a closed vascular system there are red blood corpuscles in the coelomic fluid. A similar condition is found in certain echiuroids.

Respiration.—In many Polychaeta there are no special organs of respiration, this function being performed by the vascularized integument of the entire body. In those groups in which there is no differentiated vascular system the hollow outgrowths

C. Branchial filament of *Potamilla torelli*

of the body-wall filled with coelomic fluid only are known as lymphatic branchiae. The true branchiae enclose an expansion of the vascular system in the form of a loop. Branchiae may be simple filaments as in *Nephtys*, ramified as in *Terebella* or pectinate as in *Eunice*. In the *Sabellidae* and *Serpulidae* they form in front of the head a large plume composed of numerous filaments provided with ciliated barbules. Generally in the Sedentaria they are confined to the anterior end of the body and in the Errantia they are metamerically arranged on the dorsal surface of the feet and may occur on a large number of the body-segments. (Fig. 7, a to c.)

Excretion.—Excretion is principally carried out by the segmental organs or nephridia. These consist typically of a ciliated tube often with an intercellular lumen opening into the coelom by a

ends blindly in branches provided with vibratile flame-cells or solenocytes. In the *Phyllodocidae* at the time of sexual maturity this blindly ending nephridium fuses with the large ciliated funnel and thus forms a passage for the escape of the genital products. In the *Capitellidae* the genital and excretory passages remain separated, and in many of the Sedentaria the nephridia are reduced in number and confined to the thoracic region. In the *Terebellidae* also the anterior pairs are purely excretory and the posterior act as gonoducts, a specialization of function having taken place.

Nervous System.—The nervous system consists of a dorsal nerve mass or brain which may be formed by the fusion of several pairs of ganglia, and the perioesophageal commissure or nerve loop joining the brain to the main system, the ventral nerve-chain. This chain consists of two longitudinal cords with segmental ganglionic swellings and segmental lateral nerves. The two ventral cords may be widely separated as in *Serpula* or completely fused into one as in *Arenicola*, which has no ganglionic swellings in its nerve cord. There are many intermediate stages between these two extreme conditions. (Fig. 9, a and b.)

Sense Organs.—Under this heading may be classed the eyes, the nuchal organs, the lateral organs and the tactile organs. Eyes are present in most Polychaeta dorsally on the prostomium; they occur also in other parts of the body. In certain *Opheleidae* they are ranged segmentally on the

side of the body. In *Amphiglene* the pygidium is furnished with eyes. In many *Serpulidae* the branchiae are provided with eyespots. The eyes themselves show every stage of development between the simple pigment spot and the complex organs of the pelagic *Alciopidae*, which have a crystalline lens, a retina and a vitreous body.

The otocysts, which are really organs of equilibrium rather

B. Diagram of the nephridium of *Aloiopoe* into which opens the large genital funnel (coelomostome)

vibratile funnel and to the exterior by a small pore, the nephridiopore. The segmental organs are as a rule complex organs formed by the junction of an excretory tube with a genital funnel. (Fig. 8, a and b.) In *Nephtys* in addition to the segmental organ there is a large ciliated organ in close connection with it. E. S. Goodrich considers this to be a genital funnel modified to form a phagocytic organ, for it acts as a leucocyte-collector. The leucocytes gather together the waste products and there may be a physiological connection between it and the nephridium. In *Nephtys* as in the *Glyceridae* and *Phyllodocidae* the nephridium

than of hearing, are confined to the Sedentaria. There are three types of this organ, a sac communicating with the exterior by a ciliated canal and containing a foreign body such as a grain of sand, which functions as an otolith (*Arenicola marina*, *Branchiomma*); a closed ciliated cavity containing an otolith which has been secreted (*Jasmineira*); a closed cavity without cilia which contains a number of secreted otoliths (*Arenicola ecaudata*).

The nuchal organs are ciliated pockets above the hinder portion of the brain. They are paired and sometimes eversible as in the *Glyceridae*. The lateral organs are richly innervated segmental

ciliated pads found along the side of the body in a number of families. Ciliated organs may occur as in the *Spionidae* in very different parts of the body, and Söderström thinks that certain dorsal sense organs in the latter family may function as olfactory organs and help to bring the males and females together at the time of sexual maturity.

The tactile organs are the palps, tentacles, cirri and various papillae.

Reproduction.—The Polychaeta are normally dioecious. Hermaphroditism is confined to a few species mostly belonging to the *Serpulidae*. The cosmopolitan Nereid, *Platynereis dumerilii* is notable in being polymorphic and having a hermaphrodite form. Except for the copulatory chaetae in the *Capitellidae* and for the differentiated gonad in *Arenicola ecaudata* and *Hesione sicula*, the Polychaeta do not possess specialized genital organs. The germ-cells are proliferated from the coelomic epithelium lining the parapodial blood-vessels and drop off into the coelom in which their development is completed. There is a variety of ways by which the ripe germ-cells are released, of which the commonest is by way of the segmental organs. In a few instances (*Owenia fusiformis*, *Micronereis variegata*) the eggs and sperm are set free through special anal pores, and in *Perinereis cultrifera* (male) through the anus itself. Often the body-wall is ruptured, and sometimes as in *Clitostomus lineatus* and the Palolos the modified part of the body bearing the sexual elements breaks off in its entirety from the rest. Sexual dimorphism is the exception in the Polychaeta. Those groups which pass through an epitokous phase at the time of sexual maturity, a phase which involves a kind of metamorphosis, and those groups in which reproduction takes place by budding show external differences between the sexes. Otherwise except for the copulatory chaetae in the Capitellids and the genital papillae in the Terebellids the sexes are distinguished by their germ cells alone. (Fig. 10, a to c.)

Epitoky or sexual metamorphosis is most marked in the Nereids, but it occurs also in several other families. At the time of sexual maturity a great change both external and internal takes place. The appearance of the head is much altered, the eyes grow

At the same time great internal changes take place. The muscles and digestive tube undergo histolysis, which is accompanied by a certain amount of histogenesis. According to A. Dehorne the coelomic leucocytes at this period take on the rôle of active phagocytes. The name *Heteronereis* is applied to Nereids undergoing the sexual phase. At this time the sexes are often distinguished by differences in the pygidium.

Among the Syllids reproduction takes place by budding and by fission or division of the body. To these processes the names blastogamy and schizogamy have been given. In blastogamy a parent individual, which is asexual, buds off at its posterior end a chain of sexual individuals or stolons which break away from the parent stock to lead an independent existence. Budding takes place just in front of the pygidium. The anterior segment forms a head and the remaining segments are intercalated between this and the pygidium. In *Autolytus* the male stolons are known as *Polybostrichus* and the female as *Sacconereis*. In schizogamy one of the segments of the parent individual forms a head with appendages and the stolon is formed at the expense of the posterior region of the parent's body. Often reproduction takes place by a combination of blastogamy and schizogamy, the schizogamous stolons themselves budding a number of segments before breaking away from the parent individual (*Procerastea*).

Development.—In the Polychaeta cell-division is normally spiral, and when the embryo leaves the egg-membrane and begins to lead a free larval existence it is called a Trochophore. The Trochophore is described as atrochous (*Terebella*), monotrochous (*Chaetopterus*), polytrochous (*Ophryotrocha*) according to the number and position of the ciliated bands which encircle it. (Fig. 11, a and b.) The trochophore stage is followed by a phase, often

free-swimming, in which the young differs greatly from the adult. In the course of time the various appendages are developed, the larval bristles are replaced by the adult bristles and the fully grown worm is formed.

Classification.—For a historical account of the Polychaeta the reader is referred to the introduction to J. H. Ashworth's *Catalogue of the Chaetopoda in the British Museum* (Part 1, London, 1912), and to de Quatrefage's *Histoire des Annelés* (Paris, 1865); the works mentioned in our bibliographies on pp. 994 and 998 below, should also be consulted.

Fauvel following Audouin and Milne Edwards divides the Polychaeta into the Errantia and the Sedentaria. He defines the Errantia as Polychaeta in which the segments of the body are all similar except the segments adjoining the mouth and the terminal segment or pygidium; and the Sedentaria as Polychaeta in which the body is divided into several regions, the head is small or profoundly modified, the feet are almost always simple, the ventral branches often in the form of a torus armed with hooks or uncini; the branchiae are normally confined to a definite region and the species are habitually tubicolous. W. B. Benham's arrangement of the group into seven sub-orders (Vol. II. of the *Cambridge Natural History*, 1896) is still commonly adopted.

Phylogeny.—There has been much speculation about the origin and affinities of the Annelids. The most recent is that of R. Woltereck based on his study of the development of the Archannelid *Polygordius*. Before the separation of the mouth and the anus, the Annelid Trochophore bears some resemblance to a primitive Ctenophore, and Woltereck suggests that a primitive Ctenophore-like ancestor took to a burrowing mode of life in its adult stage; that segmentation was the result of the adoption of wriggling in place of a ciliary mode of locomotion. On this hypothesis the presence of segments in the free-swimming larva has to be attributed to a telescoping of the racial history. Objections to Woltereck's hypothesis are stated at length by Söderström in his *Das Problem der Polygordius-Endolarve* (Uppsala, 1924).

FIG. 10.—REPRODUCTION

- A. Heteronereid phase of *Nereis dumerilii* (After McIntosh)
 B. The Pacific Palolo, or the epitokous phase in *Eunice viridis* (After Gravier)

to a great size and the palps shrink. The body appears to be made up of two distinct parts, the anterior end, sometimes filled with genital cells, in which the feet remain unmodified, and the posterior end in which the feet are furnished with enormous foliaceous lobes and with special paddle-shaped swimming chaetae.

Ecology.—Except for about a dozen freshwater species, mostly *Nereidae*, and half that number of euryhaline species, the Polychaeta are marine. They occur most abundantly between tide-marks and in shallow water near the shore, but they have also been dredged from very great depths. Their mode of life is very variable. Some live in tubes in the mud or sand, others in holes in the rock, or fixed to stones and shells, and in every kind of crevice. A number of species are pelagic. Others again attach themselves to Echinoderms or sponges.

Coloration.—The majority of the Polychaeta are brilliantly coloured in life, and a number, chiefly Syllids, are phosphorescent. *Chaetopterus* is also exceedingly phosphorescent, and its normal green colour is derived from the Algae on which it feeds.

Regeneration.—Autotomy is of common occurrence in the group, especially among the Polynoids and the Eunicids. In fact it is usual on examination of a member of the latter group to find that it is regenerating or has regenerated its posterior end, and the Polynoids shed and regenerate their elytra or scales with great facility.

Food.—Some Polychaeta are active and predatory carnivores with large prehensile jaws, others feed on Algae.

Many of the Sedentaria feed on small organisms in suspension in the water, which become entangled in their tentacles and gill plumes. Some like the *Arenicolidae* ingest large quantities of mud and sand and derive nourishment from the organic matter mixed with them.

Parasitism.—Parasitism is uncommon in the group. The only internal parasites known belong to the *Eunicidae*, and, with the exception of *Oligognathus bonelliae* which is parasitic in the body-cavity of *Bonellia* and the doubtful *Ophiuricola cynips* in a deep-sea *Ophiuroid*, they attack other Polychaeta only. External parasites are even rarer. *Ichthyotomus sanguinarius* is a parasite on the eel, *Myrus vulgaris*, and *Parasitosyllis* on other Polychaeta and on Nemertines.

Commensalism.—Commensalism is of common occurrence, and of all the families the *Polynoidae* are the most prone to this habit. *Polynoe rutilans* occurs with an Alcyonarian *Xenia*, *Scalissetosus communis* is found with an Ophiuroid, and *Scalissetosus echini* with *Echinus esculentus*. *Lepidasthenia pulchra* lives with a Holothurian, *Stichopus*, *Hololepidella commensalis*

that incubation and parental care are not uncommon in the group. Several species of Polynoids incubate their eggs on their backs beneath their scales. In the Syllid *Exogone gemmifera* the developing eggs are attached in longitudinal rows to the ventral surface of the mother, where they remain until they are capable of fending for themselves. Some Syllids carry their young on their backs: the Spionids lay their eggs in the tubes which they inhabit and in some species the young remain in the tubes of their parents until an advanced stage of growth. During this time a certain number of eggs and larvae cease to develop and serve as food for the others. According to Söderström in *Polydora nutrix* a portion of the maternal tissue undergoes histolysis and serves as a sort of nutritive mass in which the young develop. *Capitella capitata* and the hermaphrodite form of *Nereis dumerilii* build tubes at the time of sexual maturity, and do not leave them before their young are old enough to take care of themselves. In *Autolytus* and its allies the females at the moment of egg-laying secrete a viscous fluid which hardens on contact with the water and forms a sort of brood-pouch in which their fertilized eggs develop. C. Gravier observed a similar phenomenon in a Phyllocid *Eteone gaini*. (Fig. 12, a to c.)

Potamilla antarctica is said to keep its developing young inside its branchial plume. The spirorbids are unique in incubating their young in their operculum, which is the dilated end of a single branchia, normally used as a sort of stopper to their tube. Finally a small number of Polychaeta are viviparous, that is to say incubation takes place actually within the body of the parent. The Syllids, *Syllis vivipara* and *Ehlersia nepiotica* are viviparous, as are also a few *Serpulidae*. M. Caullery and F. Mesnil have suggested that the so-called viviparous Syllids are immature forms reproducing themselves parthenogenetically, and that when mature they are normally dioecious and behave as the rest of the family.

Tube-building.—The tubes of the Polychaeta are varied in form. Some secrete from their mucous glands, which in the Terebellids form the thick ventral gland shields, tough parchment envelopes, and others reinforce these with small particles from the surrounding medium. *Lanice conchilega* builds its tube with small shells and grains of sand, *Sabella* with small particles of mud. The *Serpulidae* secrete carbonate of lime with which their hard brittle tubes are built.

Economic.—The Polychaeta have little economic importance. *Arenicola*, the common lug-worm, several species of *Nereis*, *Marphysa sanguinea* and a *Nephtys* are used as bait by fishermen. The natives of Samoa and the adjacent islands eat the famous Palolo. At certain times of the year the posterior modified segment of the body of *Eunice viridis*, which has undergone a sexual metamorphosis, breaks off from the anterior end and laden with ripe germ-cells swarms in enormous numbers at the surface. These are collected and eaten by the natives.

Palaeontology.—Our knowledge of the geological history of the group is largely based on the study of calcareous tubes found attached to stones and to other fossils. *Spirorbis* is found in the Silurian and other Palaeozoic strata. *Serpula* is very abundant in the Jurassic where its occurrence has given rise to Serpulite chalk. The Nereidiformia, of which several species have been described from the Jurassic slate of Bavaria and from Palaeozoic beds in Canada survive mostly in the form of jaws and acicula. Walcott however in 1911 described a number of very well preserved Middle Cambrian Polychaeta from the Burgess shale in British Columbia. Many tracks and burrows in the rock of doubtful interpretation have been attributed to the Polychaeta.

Distribution.—Fauvel's contention that no well-defined zoological regions exist for the Polychaeta is now generally accepted by students of that group. Out of the five most important families of the Errantia more than one half of the total number of species known from the coasts of France are common to the Channel, to the Atlantic and to the Mediterranean. Furthermore out of 122 species collected by the Prince of Monaco at the Azores, 40 or nearly one-third are also part of the Arctic fauna and 29 are equally found in the Antarctic. Out of a total of 300 species collected by him between the Azores and Spitzbergen

B. *Grubea limbata* carrying its eggs on its back
C. *Eteone gaini* surrounding its eggs

with a *Clypeaster* and *Acholoe astericola* in the ambulacral grooves of starfishes.

A large number of Polynoids also live in the tubes of other Polychaeta, chiefly Terebellids and Serpulids. Webster found *Harmothoe parasitica* living under the scales of *Lepidometria commensalis* which is itself a commensal with *Amphitrite ornata*.

Incubation.—Many Polychaeta shed their eggs and sperm in the surrounding water and this constitutes their total reproductive activity; but an increasing number of observations show

about 60 are common to both hemispheres. Again out of a collection of 72 species from Madagascar 46 or nearly two-thirds were common to the northern part of the Indian ocean and to the Philippines. Finally a certain number of species, of which the most well known are *Serpula vermicularis* and *Nereis dumerilii*, are cosmopolitan. An examination of the littoral Polychaeta fauna of the tropics discloses a number of species which never desert the warm zones, but are found equally in the same latitudes all over the world. With regard to bathymetric distribution the greater majority of the Polychaeta are found between the tide-marks or within the 100 fathom zone. Beyond the continental shelf their number decreases rapidly.

Thus out of the Prince of Monaco's collections only 25% were found between the 1,000 and 2,000 metre line and only 5% between the 4,000 and 5,000 metre line. There are very few strictly abyssal forms, most of the examples found at great depths belonging to common littoral species.

(C. C. A. M.)

OLIGOCHAETA

Next to the Polychaeta, the largest division of the Annelida, are the Oligochaeta. More than four-fifths of the species are earthworms; also comprised within the group are a number of small or minute worms, some of fresh-water habit, others (belonging to the family Enchytraeidae) plentifully present, though inconspicuous, in cultivated ground and under stones on the shore between tidemarks. Wholly marine Oligochaeta are rare.

Oligochaeta have the wormlike segmented body with spacious body-cavity characteristic of most members of the Annelid phylum. In common with the Polychaeta they possess organs of locomotion in the form of setae (chaetae); the bundles of setae are not, as in the Polychaeta, set in parapodia, they merely protrude from the general level of the body surface. The most important distinction of the Oligochaeta from the Polychaeta, however, is that they are hermaphrodite, and have a much more complicated system of reproductive organs.

The Oligochaeta are in all probability descended from marine ancestors belonging to the group Polychaeta; the Polychaete stock has remained marine, the Oligochaete branch has wandered inland and taken possession of the earth and fresh waters; those that are now found on the shore and below low-water mark are descendants of terrestrial or fresh-water worms which are, as it were, returning towards their ancestral home. On the other hand, the Oligochaeta have in turn given rise to the leeches (Hirudinea).

Classification.—A fairly definite line can be drawn between the larger forms, living mostly in the earth—the Megadrili ("earthworms")—and the smaller forms or Microdrili which live for the most part in water or mud (though many Enchytraeid genera are terrestrial). Five families of Megadrili are recognized; the Moniligastridae, confined to India, Ceylon, the Malay archipelago and East Africa; the Megascolecidae, the largest family of all, predominating in India, Farther India, the Australasian region, over much of Africa and part of South America; the Eudrilidae, mainly Central African; the Glossoscolecidae, in South and Central America, parts of Africa and of the Mediterranean region; and the Lumbricidae, to which most of the earthworms of Europe, North America and North Asia belong. The Microdrili comprise the delicate Aelosomatidae and Naididae, fresh-water worms, cosmopolitan in distribution, of small size, fascinating objects of microscopical study; the Tubificidae, fresh-water and mud dwellers, mainly in the northern hemisphere and predominantly in the temperate zone; the Enchytraeidae, a numerous group, terrestrial,

littoral, occasionally fresh-water, mainly in the Arctic and temperate regions of the northern hemisphere; the Lumbriculidae, fresh-water, in Europe, Siberia and North America north of Mexico; and the small families Phreodrilidae, Haplotaxidae, Alluroididae and Branchiobdellidae, the last named all external parasites of crayfish.

The terms Terricolae and Limicolae, *i.e.*, earth-dwellers and mud-dwellers, are sometimes used, rather loosely perhaps, and correspond generally to Megadrili and Microdrili (exclusive, perhaps, of the Enchytraeidae) respectively. There are however not a few Megadrili, "earthworms" by outward appearance and affinities, which live in marshy or even aquatic habitats.

Comparative Anatomy.—In fig. 13 a marked external ringing indicates the division of the body into a series of more or less similar segments. In size, selected individuals of some of the largest species measure between three and four feet, while *Megascolecides australis* is recorded as having attained a length of six or even seven feet. But taking earthworms in general, the British Lumbricidae are perhaps rather above the average in size. The Microdrili are usually much smaller; some species of Aelosomatidae and Naididae are only about one millimetre in length, while the majority of Enchytraeidae are less than an inch. In fully mature worms the clitellum appears as a thickening of the body, girdle-like and extending over several segments; the surface cells of this region secrete, at the time of egg-laying, a cocoon in which the eggs are received, and in which the early stages of the development of the young are passed through.

FIG. 13.—ANTERIOR END OF THE LUMBRICUS TERRESTRIS, THE COMMON BRITISH EARTHWORM (VENTRAL VIEW)

The mouth is overhung by the prostomium, a small lobe in front of the first true segment. The setae, four couples per segment begin in segment II. The swollen region embracing segments xxxii-xxxvii is the clitellum. Life size

The setae (fig. 14) are rodlike or sometimes hairlike structures implanted in the body-wall; the rodlike setae are relatively short and project only slightly, while the hairs are longer and project to a greater extent; the hairs are found only in a few families of Microdrili. The setae of earthworms are in general like that represented for *Lumbricus* (fig. 14a); a greater variety occurs among the Naididae and Tubificidae. They are organs of locomotion; an earthworm uses them for obtaining a hold on the substratum, and then draws up the hinder part of the body; it then extends the anterior end, takes a fresh purchase with the setae of its front region, pulls up the hinder part again, and so on. The Limicolae use their rodlike setae on the substratum in the same way; but the bundles of hair-setae are swimming organs. In most earthworms there are eight setae per segment, arranged as two couples on each side, one couple (ventral) low down, the other (dorsal or lateral) higher up on the side of the worm. In some earthworms the number of setae is much larger; there may be any number from eight to 100 or more, and they are then arranged in a ring round each segment. In the commoner forms of Microdrili the setae, while arranged, as in most earthworms, in dorsal and ventral bundles, are not limited to two per bundle; the number per bundle varies, but may be as many as 16 or occasionally even more.

The body-wall, body-cavity, vascular and nervous systems are of the general Annelid type. The excretory organs are nephridia. In connection with the alimentary canal may be mentioned (a) the gizzard, a strongly muscular section of the gut, present in most earthworms, the function of which is to grind up the ingested earth and so facilitate digestion of the contained organic matter; it is absent in the Limicolae. (b) The calciferous glands appear in many forms; they are essentially a part of the oesophagus,

which is either merely dilated or pouched outwards so as to form saccular appendages; the lining of the oesophagus, or of the sacs, is thrown into an often very complex system of folds, within which there is a copious circulation of blood. The glands are present in many but by no means all earthworms; their function is hardly yet fully known. In the Lumbricidae, and in a few worms belonging to other families, small crystals of calcium carbonate are produced between the folds and are discharged into the main cavity of the alimentary tube; this may serve to neutralize the humus acids in the earth ingested by the worms; it may also be a means of getting rid of the carbon dioxide produced in the organism, and the glands may in this sense be respiratory organs. But it is not certain that such a secretion is produced by all the structures grouped together under the name calciferous glands.

A few aquatic Oligochaeta possess branchiae (gills), processes of the body-wall with a copious blood supply, as organs of respiration; but in general respiration is carried out through the unmodified body-wall. Sense organs are not well developed in the Oligochaeta. Earthworms avoid light, except of a very low intensity; the perceptive organs are certain specially constituted cells of the surface layer; the segments at the anterior and posterior ends are the most sensitive to light, and in these regions the sensory cells are most numerous. Some of the small freshwater Naididae have a pair of black eye-spots on the head. Other specially modified cells of the surface layer, in both Mega- and Microdrili, and the free endings of fine nerve-twigs between the surface cells, are also doubtless sensory, and may have to do with the perception of mechanical and chemical stimuli. Earthworms can distinguish between the taste of different vegetable foods; but no special organs are known. All Oligochaeta are hermaphrodite. The testes are either one or two pairs, the ovaries usually a single pair; they are situated in the anterior part of the body—in the Lumbricidae in segments x. and xi. (testes) and segment xiii. (ovaries). Before being shed, the male cells usually develop and ripen in sacs known as seminal vesicles, the female cells in the cavity of the ovarian segment or in special ovisacs; the genital products reach the exterior by special ducts, the endings of the male ducts being seen in the common Lumbricidae on segment xv. as slitlike apertures on prominent papillae. In many worms (but not in the Lumbricidae) glandular organs (so-called prostate glands) open near or in common with the endings of the male ducts. Spermathecae are generally present.

Reproduction and Development.—Though the Oligochaeta possess both male and female organs, fertilization of the eggs by the animal's own sperms never, so far as is known, occurs (except perhaps in the common fresh-water *Tubifex*). In copulation mutual transfer of sperms takes place, and the partners separate; at a subsequent period the eggs attain maturity; a secretion of the clitellum, soft at first but rapidly hardening to a hornlike consistence, forms the cocoon, which is passed forwards over the animal's head. As the cocoon passes over the female apertures the eggs are discharged into it, and as it passes over the apertures of the spermathecae sperms received in copulation are ejected into it; fertilization of the eggs takes place immediately. The ends of the cocoon close up, owing to elasticity, when it becomes free from the worm. The young are nourished by an albuminous fluid contained within the cocoon, produced by certain gland cells of the clitellum at the time the cocoon is formed. They hatch out as young worms after some weeks, the length of time varying with the temperature.

FIG. 14.—SETAE OF CERTAIN OLIGOCHAETE WORMS
The seta of *Lumbricus terrestris* is shown implanted in the body wall. A fine transparent web stretches between the terminal prongs of the needle-seta of *Aulophorus carteri*. Magnification is respectively X 45; X 400: X 625

In the families Aeolosomatidae and Naididae the above (or sexual) mode of reproduction is largely replaced by fission, an asexual process, in which a worm divides into two, with the formation of a new tail in the case of the anterior, a new head in the case of the posterior of the two animals so produced.

Zoogeographical Distribution.—*Aeolosoma* and several genera of Naididae (small fresh-water forms) are cosmopolitan; even the same species is sometimes found in widely separated localities, even in different continents. This is due to the ease with which they or their cocoons can be transported; they can without difficulty colonize the whole of a river system once they gain an entry; they, or more often their cocoons, may be carried in the mud on the feet of water-birds from one pond or lake to another, or from one river-system to another. The same considerations apply to the Tubificidae and other Limicolae.

The species of earthworms are on the whole much more localized; instead of being passively carried by the stream, or casually transported (themselves or their cocoons) in mud, their migrations are in the main due to themselves alone, and largely to their slow tunnelling through the soil; streams, deserts, rocky or snow-clad mountain ranges form insuperable obstacles. Yet even among earthworms there are many species which have a wide distribution; some of the common Lumbricids are found in all parts of the world where European intercourse has penetrated (e.g., *Allobophora caliginosa*, perhaps the commonest of all earthworms); some species of the Far Eastern genus *Pheretima* are now circum-mundane in the warmer regions of the globe. It is evident that this can only have come about by their (or their cocoons) having been passively transported. Certain species, in fact, are now recognized as being very liable to accidental transportation, and as being able, when thus transported, to establish themselves with ease in new surroundings; insomuch that near South American and Australian towns with considerable European intercourse the indigenous earthworms have been entirely displaced by Lumbricid intruders, and have to be sought in the remoter parts of the country. Species which spread in this way are known as peregrine.

It is obvious that no general conclusions can be drawn from the distribution of the peregrine earthworms and the Limicolae. But the case is different with those genera of earthworms which do not bear artificial transportation readily, which spread slowly and which are limited by the physical features of the land; if, for example, the same genus is found in two regions now entirely cut off from each other by sea, this is presumably because these regions were at one time united by a land bridge. The Oligochaeta are thus of much value to the science of Palaeogeography.

Natural History and Behaviour.—Some degree of moisture to prevent their desiccation, and some admixture of organic matter in the soil to furnish them with food, are for earthworms necessary conditions of existence; they are therefore not found in desert tracts, nor in pure sand. They live principally in the surface layers of the soil, but penetrate more deeply in winter, since the temperature is higher and more constant at deeper levels; in hot weather also, especially in warm countries, they retreat downwards to avoid desiccation; Darwin met with burrows between five and six feet from the surface, and quotes other observers who found burrows going down to 6–8 feet.

The number of worms in the soil varies widely according to the nature of the soil, and may be very large; the numbers per square metre given by different observers range from about 30 to 2,000; in meadows and garden earth 300–1,000 seem to be usual. But the small Enchytraeidae are much more numerous; in Switzerland, Bretscher found 1,650–8,000 per square metre.

Earthworms are nocturnal animals, retreating into their burrows in the daytime, and emerging at night. As a rule, while protruding and gathering the vegetable debris within their reach, they maintain their hold on their burrows by their tail. In forming their castings, however, the hinder end is protruded; the ejected earth is deposited with some care, first on one then on the other side around the mouth of the burrow. The castings thus surround and cover the aperture; the mouth of the same burrow is used for this purpose for some time, so that each mass is the product of several operations or of several worms. Castings may be of

considerable size; the largest Darwin could find at Down weighed nearly four ounces; in warmer countries they may be larger.

The burrows of earthworms are excavated in two ways, by pushing the earth away on all sides, and by swallowing it. The burrows run more or less perpendicularly, and seldom branch; they are lined with a firm smooth layer of fine earth voided by the worms, and so may be compared to tunnels lined with cement.

Earthworms drag leaves, seeds and other portions of plants into their holes, and parts of these, at least, they eat; they also ingest earth, utilizing the organic matter contained in it as food. They will devour raw fat, raw and roasted meat and dead worms if placed within their reach.

A number of earthworms are luminescent, among them the common *Eisenia foetida* (the brandling). The light is given off by a fluid which escapes from mouth and anus, or in some cases from the dorsal pores (apertures in the body-wall along the middle line of the back); the ultimate source of the fluid is in either case the body-cavity.

Economic and General.—Earthworms are continually engaged in swallowing earth below ground and evacuating it on the surface; Darwin calculated the quantity of earth thus brought up to be from $7\frac{1}{2}$ to 18 tons per acre per year, equivalent in ten years to a layer 1–2 inches thick. Lime, flint, cinders, etc., and even larger stones and boulders, are gradually covered; ancient roads, pavements, tiled floors, walls and ruins are buried and preserved for the archaeologist. As to the soil itself, the mould is triturated and sifted, no particles larger than earthworms can swallow being left in it; it is periodically exposed to the air; organic matter is added to it from the leaves, etc., which are dragged into the burrows. The burrows admit of the aeration of the soil, and aid materially in its drainage; they facilitate the downward passage of roots. Many seeds owe their germination to having been covered by castings; in some cases earthworms act as actual tree-planters, by dragging seeds, e.g., the winged seeds of the silver maple, into the ground.

The chief economic use of Oligochaeta at the present day is as bait in fishing. Worms from Thames mud, doubtless Tubificidae, used to be sold to feed fish in aquaria; and Tubificid worms are sold as food for goldfish in Japan. Certain earthworms were until recent times used as food by the Maoris. Earthworms have often been employed in medicine; passing over their use in antiquity and the middle ages, they are given at the present day in China and Japan in fever, in Burma in a variety of affections and in Gippsland in Australia for rheumatism. See EARTHWORM.

BIBLIOGRAPHY.—C. R. Darwin, *The Formation of Vegetable Mould through the Action of Worms, with Observations on their Habits* (1881), still contains the best account of the activities and manner of life of earthworms; F. E. Beddard, *A Monograph of the Order of Oligochaeta* (1895), though now somewhat antiquated, is the latest monograph on the whole subject; W. Michaelsen, "Oligochaeta," in *Das Tierreich* (1900), systematic only; F. E. Beddard, *Earthworms and their Allies* (1912), handy, semi-popular; H. Friend, *The Story of British Annelids* (1924), popular. (J. St.)

HIRUDINEA

The Hirudinea or, popularly, leeches, are hermaphrodite Annelids provided with a sucker at both ends. There are no parapodia or chaetae, except in *Acanthobdella*, a form which is assigned by some authorities to the Oligochaeta. There are no appendages except branchiae, which occur in a few species. The number of segments is constantly thirty-four. The coelom is reduced to a series of intercommunicating spaces except in *Acanthobdella*, where it consists of a series of segmental chambers as in the Oligochaeta. A clitellum is present and the testes are usually numerous and continuous with the sperm-ducts. There is a single pair of ovaries continuous with the oviducts and the sexual pores are median and single. The nephridia are paired, always with an intracellular lumen and often with closed funnels; rarely they form a network from segment to segment. Eyes are usually present and the nervous system lies in the coelom. The Hirudinea are aquatic, terrestrial and marine; they are carnivorous and parasitic.

Annulation.—The limits of the segments in the Hirudinea are obscured by the presence of annuli or rings, which in the

fully developed segment of the middle body may vary in number from two to fourteen. The 34 segments correspond to and are innervated from 34 ganglia in the nervous system; and the number of segments and their limits is determined by the number and position of the ganglia. The ring in which the sensillae or segmental sense organs externally and the ganglia internally are located is normally the central ring of the segment.

External Anatomy.—Leeches vary in size from about 5 millimetres to 18 inches, and their shape changes according to their state of contraction; they may be linear, oviform, subcylindrical or foliaceous; in life many species are brilliantly coloured with a variety of elaborate colour patterns.

The body may be divided into five regions. The *cephalic region*, consisting of six segments, the majority of which are composed of a single ring, includes the anterior sucker, the mouth, the eyes and the jaws, when present. The anterior sucker may be discoid as in the majority of the *Ichthyobdellidae* or spoon-shaped as in most *Arhynchobdellidae*. The eyes are often complex, consisting of an optic nerve and ganglion, a sheath of visual cells containing a vitreous body, the whole surrounded by a dense cup of pigment. The second region or *pre-clitellum* contains the pharynx and anterior nephridia, and is marked by the intermediate condition of development of the segments. The middle region, further divided into the *clitellum* and *post-clitellum*, contains the main part of the organs of the reproductive, digestive and excretory systems. The clitellum, which usually extends over three complete segments, consists of a thick layer of unicellular glands. The postclitellum is followed by the *anal region*, in which the segments are again incomplete. This leads to the posterior sucker, composed of segments 28 to 34, disc-like and directed ventrally except in the burrowing *Lumbricobdella*; it constitutes the *caudal region*.

The sensillae or segmental tactile organs are found on the sensory ring of each segment. They appear as round white patches on the skin, and there are usually four to six pairs to each ring; they are provided with sensory hairs and are retractile.

Internal Anatomy.—The nervous system is Annelidan in character, consisting of a double nerve cord with segmental ganglia and lateral nerves. The cords diverge in front to loop round the oesophagus and meet above in the supraoesophageal nerve mass or brain. The six ganglia of the cephalic region are fused into a suboesophageal ganglionic mass below the alimentary tract, and a similar condition prevails with the seven ganglia of the caudal region.

The musculature is very complex; besides the main oblique, circular and longitudinal layers, of which the last are the thickest, there are vertical and transverse sheets of fibres.

Coelom.—The most remarkable feature of leech morphology is the coelom or body-cavity. In *Acanthobdella* its condition resembles that found in the Oligochaeta, but in other leeches it is largely filled by the growth of connective tissue of various kinds and reduced to a series of canals or lacunae connected by an elaborate system of delicate branches. In the *Glossiphoniidae* there are five main longitudinal lacunae; hypodermal lacunae are also present in the form of fine canals running round the body just beneath the skin. By bringing the contained coelomic fluid

FROM HARDING AND MOORE, "HIRUDINEA," FAUNA OF BRITISH INDIA, BY COURTESY OF SECRETARY OF STATE FOR INDIA IN COUNCIL
FIG. 15.—EXTERNAL ANATOMY OF A TYPICAL TEN-EYED LEECH

The somites are indicated on the left side by Roman numerals and the annuli on the right by Arabic numbers. Eyes, sensillae, nephropores, gonopores and anus are also shown

close to the air they assist in respiration. Most of the *Ichthyobdellidae* possess strongly contractile lateral lacunae, and certain members of the family have pulsating vesicles beneath the skin, resembling cutaneous sacs which are rhythmically inflated and deflated. These are filled with coelomic fluid from a branch of the segmental lacunae encircling the body, and the contraction of the muscular walls of the vesicles drives the fluid into the lateral lacunae; the vesicles are provided with a valve formed by an invagination of the wall, which opens and closes as they pulsate.

The *Rhynchobdellidae* have a closed vascular system in addition to the lacuna system, and in the *Arhynchobdellidae*, in which the obliteration of the coelom has advanced still farther, the lacuna system, wholly or in part, takes the place of the vascular system of the former family; in the *Arhynchobdellidae* the coelom is invaded by the so-called botryoidal tissue, consisting of curious pigmented and excavated cells, the precise function of which is still not fully understood.

Vascular System.—The true vascular system of the *Rhynchobdellidae* consists typically of a dorsal and a ventral vessel running the length of the body and connected at the extremities by a system of branches: anteriorly a part of the dorsal vessel is muscular and contractile, functioning as a heart; and the dorsal

the *Rhynchobdellidae* a large cavity surrounding the eversible pharynx or proboscis. The oesophagus leads into the stomach or crop, usually provided with caeca, and essentially an organ of storage; the crop is followed by the intestine, a long straight tube except in the *Hirudidae*, in which it is sacculated. The rectum is a simple tube leading to the anus.

Reproductive System.—The leeches are hermaphrodite with paired male and female organs. The testes are segmentally arranged, except in certain *Arhynchobdellidae* in which they are subdivided into numerous small ovoid bodies. A small segmental duct leads to the *vas deferens* on each side, which enlarges anteriorly to form an epididymis or sperm-vesicle; this leads into the *ductus ejaculatorius*, which finally empties into the common eversible male organ. The female organs consist essentially of two large ovisacs, containing the ovaries and leading to the exterior by a common female aperture.

The sperm is packed in spermatophores, in which it is conveyed from one individual to another. Copulation occurs in the *Hirudidae* by means of the eversible male organ, but in the other families impregnation is normally hypodermic. One leech plants a spermatophore upon the body of another leech; the sperm escapes and makes its way through the tissues into the ovisacs where fertilization takes place. In many groups the spermatophores have to be planted on a definite area of the body, beneath which lies the special conductive tissue through which the sperm passes.

Nephridia.—The convoluted nephridia are formed of rows of tubular cells set end to end like drain-pipes. Externally they open by a vesicle on the ventral surface of the segment, and the internal funnel communicates with the lacuna system.

Phylogeny and Classification.—There is much evidence to show that the leeches are derived from the Oligochaeta. Apart from *Acanthobdella*, to whose systematic position reference has already been made, the leeches are divided into two suborders:—the *Rhynchobdellidae*, marine and freshwater leeches with colourless blood, with an exsertile proboscis, without jaws; and the *Arhynchobdellidae* or *Gnathobdellidae*, freshwater and terrestrial leeches with no proboscis, typically with jaws, with red blood.

Development.—The eggs are laid in cocoons formed from glands in the clitellum; segmentation is unequal and in the *Arhynchobdellidae* the young hatch early and swim about inside the cocoon, feeding on the contained albumen. After leaving the cocoon the young often attach themselves to the ventral surface of their mother.

Distribution.—The Continental leeches are limited in range, both vertically and horizontally, by temperature alone. Below 40°F they cease to be active, and consequently they are not found in the polar regions or above certain altitudes in the mountain ranges. The marine leeches, however, are carried by their piscine hosts far into the polar seas.

Economics and Ecology.—A brief sketch of the economic relations of leeches is given in the article LEECH. For further information and for an account of their habits, with special reference to tropical forms, the reader is referred to Harding and Moore's "Hirudinea," *Fauna of British India* (London, 1927).

(Contains a good historical account, a good but incomplete sketch of the morphology, much information regarding habits, distribution and economics, and an extensive bibliography.) W. A. Harding, "A revision of the British Leeches," *Parasitology*, III. (2) (1910; very good bibliography). An extensive bibliography is also to be found in C. Pinto, "Enseio Monographico dos Hirudineos," *Revista de Museum Paulista* (1923). (C. C. A. M.)

MYZOSTOMARIA

The Myzostomaria are small aberrant annelids living as external or internal parasites on echinoderms. The great majority of their hosts are crinoids; a few are among the ophiuroids and asteroids. Originally attributed by Leuckart to the trematodes, the Myzostomaria have been put by various authors among the turbellarians, the leeches, and even among the Crustacea; but their trochophore larva is undoubtedly annelidan, and they are now regarded as a modified branch of the Polychaeta.

FROM HARDING AND MOORE, "HIRUDINEA" FAUNA OF BRITISH INDIA, BY COURTESY OF THE SECRETARY OF STATE FOR INDIA IN COUNCIL

FIG. 16.—THE GENERAL INTERNAL ANATOMY OF A TYPICAL TEN-EYED LEECH, BASED ON *HIRUDINARIA GRANULOSA*. THE ROMAN NUMERALS INDICATE THE SOMITES

vessel expands into an intestinal blood sinus surrounding the gut; the peristaltic contractions of the intestine drive the blood out of this sinus through a series of valves, which close behind it, into the heart-region, from which it receives a further impetus.

Alimentary Canal.—The alimentary canal is divided into oral chamber, buccal sinus, pharynx, oesophagus, stomach, intestine, rectum and anus. The oral chamber is the cavity of the anterior sucker leading into the buccal sinus, in the *Arhynchobdellidae* a shallow cavity containing the jaws, when present, and in

Morphology.—The body is discoid, oval, or more rarely oblong, furnished along its edge with usually ten pairs of more or less well-developed cirri. On the ventral (very rarely on the lateral) surface there are five pairs of parapodia provided with acicula and hooks; the latter consist of a stout hooked chaeta supported by a bristle with a membranous or chitinous expansion at its tip. There are normally four pairs of suckers, homologous with the lateral sense-organs of the Polychaeta, and alternating with the parapodia. An anterior ventral mouth leads into an unarmed retractile pharynx provided with a bulbus musculosus. The pharynx is followed by a stomach and an intestine; the stomach sends off a varying number of caeca. There is a terminal cloaca.

The body cavity is reduced to a space above the mid-gut and a pair of latero-ventral cavities; the former serves as an ovisac from which comes off a duct opening into the common cloaca; the latter give rise to the testes and their ducts which end in penis-papillae at the root of the third parapodium of either side. The circulatory system consists of a series of intercellular lacunae filled with coelomic fluid. The nervous system, consisting of a ventral nerve-cord and an oesophageal loop, is of the rope-ladder kind. Except in *Protomyzostomum* there is only a single pair of nephridia.

Classification.—Von Stummer-Traunfels recognizes four families: The *Myzostomidae*, with 106 species; the *Protomyzostomidae*, with 3 species; the *Mesomyzostomidae*, with 1 species; and the *Stelechopidae* with 1 species. They are distinguished by the number of intestinal caeca, position of the parapodia, etc.

Ecology.—The *Myzostomaria* climb by means of their hooks on the disc and arms of their hosts or form a kind of gall upon them: sometimes they are internal parasites and live in the digestive tract or the gonad of their host. They are normally protandric hermaphrodites. The young animal functions as a male and then, when the sperm has been discharged and the eggs are ripe, it be-

AFTER VON STUMMER-TRAUNFELS IN KÜKENHAL AND KRUMBACH, "HANDBUCH DER ZOOLOGIE." BY PERMISSION OF WALTER DE GRUYTER & CO.

FIG. 17.—MYZOSTOMUM ANTARCTICUM

Semi-diagrammatic figure of the anatomy seen from the ventral surface comes a female; when the eggs ripen before the total emission of the sperm a true hermaphroditic phase ensues; otherwise there is an immature stage between the male and female conditions. Certain species carry on their backs young forms still functioning as males.

BIBLIOGRAPHY.—The best account of the group with an extensive bibliography is that of von Stummer-Traunfels in the *Handbuch der Zoologie*, W. Kükenthal and T. Krumbach, Band III., pp. 132-210, text-figs. (1926). P. Fauvel gives a good and concise account of the European forms in "Polychètes sédentaires," etc. *Faune de France*, xvi., pp. 445-450, text-figs. (1927). (C. C. A. M.)

ANNEN, a town in the Arnsberg district of the Prussian province of Westphalia, 6m. S.W. of Dortmund. Pop. (1925) 17,831. Coal-mining is carried on and glass, soap, chemicals and metals manufactured.

ANNEXATION, a formal act of state (*see* ACT OF STATE), whereby a state claims *dominium* or sovereignty over territory which is unoccupied by civilized people, or which is occupied by its own subjects, or over which it has established a protectorate, or which it has occupied by treaty, or which has been subjugated by its armed forces. Annexation alone is incapable of giving a good title. In the case of territories which are no part of the possessions of any civilized state, annexation must be accompanied by settlement. It matters not which comes first, but there must be some formal act of annexation. This is usually the hoisting of the national flag and the reading of a proclamation declaring the intention of the annexing state to take the territory in question as its own. If subordinate authorities perform the act of annexation their proceedings are invalid until ratified by their supreme government. Thus when Queensland in 1883 annexed the greater part of New Guinea together with New Britain, New Ireland and other islands, Great Britain only ratified the annexation of a portion of the south-east of New Guinea, after which Germany annexed another portion and established a protectorate over New Britain and New Ireland. A protectorate has frequently been a first step to annexation. Thus France which had in 1885 acquired a protectorate of Madagascar by treaty, in 1896 annexed it as a colony of the republic. Thus in 1908 Austria formally annexed Bosnia and Hercegovina, which she had occupied by virtue of the Treaty of Berlin, 1878; and in 1914, on the outbreak of the war with Turkey, Great Britain annexed Cyprus, which she had administered under the suzerainty of the Sultan. The proclamations by Lord Roberts in 1900 of annexation of the Orange Free State and the South African republic were premature and invalid, since the war did not terminate for nearly two years. A good title was only acquired by the cession of these territories by the Boer generals by the Convention of Vereeniging, 1902. The surrender of territories by Germany and her allies in the peace treaties following the World War, although substantially annexation by conquest, was legally cession by agreement. Consequently the title of the succession States is founded on cession. For the legal effects of annexation *see* STATE SUCCESSION.

See C. F. Randolph, *Law and Policy of Annexation* (1901); T. J. Lawrence, *The Principles of International Law*, 7th ed. 1923. (H. H. L. B.)

ANNICERIS, a Greek philosopher of the Cyrenaic school. A follower of Aristippus, he denied that pleasure is the general end of human life. To each separate action there is a particular end, namely the pleasure which actually results from it. Secondly, pleasure is not merely the negation of pain. There is, however, an absolute pleasure in certain virtues such as belong to friendship. In these a man will have pleasure, even though it may result in painful consequences. He maintains, in opposition to most of the Cyrenaic school, that prudence alone is an insufficient guarantee against error. The wise man is he who has acquired a habit of wise action; human wisdom is liable to lapses at any moment.

ANNING, MARY (1799-1847), English fossil-collector, was born at Lyme Regis. When but a child in 1811 she discovered the first specimen of *Ichthyosaurus* which was brought into scientific notice; in 1821 she found remains of a new saurian, the *Plesiosaurus*, and in 1828 she procured, for the first time in England, remains of a pterodactyl (*Dimorphodon*).

ANNISTON, a city of Alabama, U.S.A., 56 m. E. by N. of Birmingham, on the slope of Blue mountain, the county seat of Calhoun county. It is on the Bankhead highway, and is served by the Southern and the Louisville and Nashville railways. The population was 17,734 in 1920, of whom 5,834 were negroes, and was 22,345 in 1930.

Anniston is a trade centre for cotton and other products, and has extensive manufactures, especially of iron, steel, cotton and chemical products. The output of the 51 establishments in 1927 was valued at \$12,115,000. Camp McClellan, a permanent post of the U.S. Army, is situated here.

An iron furnace was built on the site of Anniston during the Civil War, and was destroyed by Federal troops in 1865. The city was founded in 1872 as a private enterprise by the Woodstock Iron Company, chartered as a city in 1879, and opened for general settlement in 1884.

ANNO or **HANNO, SAINT** (c. 1010–1075), archbishop of Cologne, belonged to a Suabian family, and was educated at Bamberg. He became confessor to the Emperor Henry III., who appointed him archbishop of Cologne in 1056. Anno was the leader of the party that abducted the young King Henry IV. from his mother Agnes. He then seized the regency, but was compelled to share it with Adalbert, the powerful archbishop of Bremen. In 1064 he left the court, but recovered some of his former influence on Henry when Adalbert fell in 1066. His most important service was his action at the Council of Mantua (May 1064) when he secured the recognition of Alexander II. as pope, against his rival Honorius, who was originally a nominee of the German Court. He was killed at Cologne on Dec. 4 1075, and canonized in 1183.

BIBLIOGRAPHY.—A *Vita Annonis*, written about 1100, appears in the *Monumenta Germaniae historica: Scriptores*, Bd. xi. (Hanover and Berlin, 1826–92). See also the *Annolied*, or *Incerti poetae Teutonici rhythmus de S. Annone*, written about 1180, and edited by J. Kehrein (Frankfort, 1865); Th. Lindner, *Anno II. der Heilige, Erzbischof von Köln* (Leipzig, 1869).

ANNOBON or **ANNO BOM**, an island in the Gulf of Guinea, in 1°24' S. and 5°35' E., belonging to Spain. Length about 4m., breadth 2m., and area 6½ square miles. It presents a succession of beautiful valleys and steep mountains, covered with rich woods and luxuriant vegetation, and culminating in the Pico de Fogo (about 3,000ft.) an extinct volcano with a crater lake. The inhabitants number (1926) about 2,000, the chief settlement being San Antonio de Praia, which has a poor roadstead. Ships can obtain here water and fresh provisions. The island was discovered by the Portuguese on Jan. 1, 1473, from which circumstance it received its name (=New Year). Annobon, together with Fernando Po, was ceded to Spain by the Portuguese, by the treaty of El Parado, 1778, with a stipulation for the continuance of "free and open traffic and commerce in negroes." The Portuguese had valuable plantations, and in their hands Annobon was of some importance. The islanders are negroes, believed to be the descendants of a cargo of slaves shipwrecked there in the 16th century, with an admixture of Portuguese blood, and professedly Roman Catholics. They revolted against the Spaniards and kept practical independence until the time of the partition of Africa, when, about 1885, Spanish authority was established. The governor general of Spanish Guinea is represented by a native deputy.

See Arnold Schultze, "Die Insel Annobon" in Petermann's *Mitteilungen*, band lix. (1913) with map.

ANNOA, in Roman mythology, the personification of the produce of the year (Lat. *annus*, year). Her attributes in works of art and on imperial coins were a corn-bushel, a ship's prow pointing to the transport of the grain over the sea, ears of corn, and a horn of plenty (*cornu copiae*).

The Latin word itself has various meanings: (1) the produce of the year's harvest; (2) all means of subsistence, especially grain stored in the public granaries for provisioning the city; (3) the market price of commodities, especially corn; (4) a direct tax in kind, levied in republican times in several prov-

inces, chiefly employed in imperial times for distribution among officials and the support of the soldiery.

In order to ensure a supply of corn sufficient to enable it to be sold at a very low price, it was procured in large quantities from Umbria, Etruria and Sicily. Almost down to the time of the empire, the care of the corn-supply formed part of the duties of the aedile (q.v.), and possibly of certain special commissaries. As a consequence of the second Punic War, Roman agriculture was at a standstill; accordingly, recourse was had to Sicily and Sardinia (the first two Roman provinces) in order to keep up the supply of corn; a tax of one-tenth was imposed on it, and its export to any country except Italy forbidden. The price at which the corn was sold was always moderate; the corn law of Gracchus (123 B.C.) made it absurdly low, and Clodius (58 B.C.) bestowed it gratuitously. The number of the recipients of this free gift grew so enormously that both Caesar and Augustus were obliged to reduce it. From the time of Augustus to the end of the empire the number of those who were entitled to receive a monthly allowance of corn on presenting a ticket was 200,000. A *praefectus annonae* was appointed by Augustus to superintend the corn-supply, who was assisted by a large staff in Rome and the provinces. In the 3rd century bread formed the dole. The office lasted till the latest times of the empire.

ANNONAY, a town in France, dept. of Ardèche, 50m. S. of Lyons by the P.L.M. railway. Pop. (1926) 13,218. Annonay is built on a hill above the confluence of the deep gorges of Déôme and Cance (tributaries of the Rhône), which supply power to local factories. A reservoir constructed in the Ternay

THE CENTRAL SQUARE AT ANNONAY, NOW THE PLACE MONTGOLFIER, AS IT APPEARED IN 1783 AT THE TIME OF THE FAMOUS FLIGHT OF JOSEPH AND ÉTIENNE MONTGOLFIER, WHO INVENTED THE BALLOON

valley, an affluent of the Déôme, to the north-west of the town, provides water for industrial and domestic purposes. The brothers Montgolfier, inventors of the balloon, and Marc Seguin, engineer, were natives of Annonay. A tribunal of commerce, a board of trade-arbitrators, and chambers of commerce and of arts and manufactures are among the public institutions. Annonay is the principal industrial centre of its department, making paper, silk, leather, etc.

ANNOY, to vex. In the sense of "nuisance" (q.v.) "annoyance" is found in the English "Jury of Annoyance" appointed by an act of 1754 to report upon obstructions in the highways.
